LONGMAN, BROWN, GREEN, AND LONGMANS,

PATERNOSTER ROW.

1842.

PREFACE.

THE advantages of Encyclopædias are now so universally acknowledged, that it would be wholly superfluous to endeavour to recommend the present work by dwelling on their peculiar merits. But though the utility of such works be no longer in dispute, it may, notwithstanding, be reasonably supposed that at a period when so many voluminous Encyclopædias, and special Dictionaries, have recently issued, and are still daily issuing from the press, this department of literature must be fully occupied, and that there can be no well-founded call for any farther addition to the number.

It will be found, however, on a little consideration that this is by no means the case. By far the greater number, or rather, perhaps we might say, all the Encyclopædias and Dictionaries of modern times, are either too voluminous or too special for ready reference and general use. The *Encyclopédie Française*, *Rees's Cyclopædia*, the *Encyclopædia Britannica*, the *Encyclopædia Metropolitana*, and the *Penny Cyclopædia*, are all works of vast extent, comprising many volumes, and embracing an infinite variety of articles, or rather treatises, which, if published separately, would each make a considerable work. Now it is obvious that such voluminous publications, whatever may be their merits in other respects, want that facility of reference and precision of statement which ought to be the distinguishing features of a useful Dictionary. No man can carry about with him any of the great modern Encyclopædias; while the extensive plan on which they are compiled renders them at once far too expensive for general circulation, and wholly unsuitable for ready consultation. The supply, indeed, of that concise and authentic information on the various subjects of science, literature, and art, which a book of reference should furnish with the utmost facility to all classes of readers, has been but a secondary object with the compilers of our great Encyclopædias; and though it had been otherwise, the length, theoretical character, and frequent obscurity of the articles in such works, must have effectually precluded their ever being used for mere purposes of reference. They are valuable as substitutes for libraries, as repositories of the various knowledge connected with the different departments of which they treat; and being so, they cannot be convenient manuals.

Special Dictionaries, on the other hand, though they may exhaust some one branch or department of science, literature, or art, and be invaluable to those engaged in its cultivation, and to those who wish to become acquainted with its details, are not intended to supply information on other branches. A work therefore like that now offered to the public, possessing the comprehensive character of a general encyclopædia without its amplitude, and

affording in a convenient form an abstract of the principles of every branch of knowledge, and a definition and explanation of the various terms in science, literature, and art which occur in reading and conversation, appears to be still wanting.

May we hope that this desideratum which has been long felt to exist in encyclopedical literature, has been at length supplied! Such at least will be the case, should the present work answer the expectations of its authors and publishers. They have endeavoured to produce a condensed and compendious Dictionary, of a convenient size, and adapted to the wants and means of all classes, that may be advantageously used as a manual or reference book in every department of science, literature, and art: and they flatter themselves that by rejecting all discussion and details not indispensable to the proper elucidation of the different topics, the work will be found, notwithstanding its comparatively narrow limits, to furnish, in the readiest possible manner, precise and accurate information on the all but infinite variety of subjects which it embraces. Great pains have been taken to make the definitions and explanations correct, clear, and concise. The principles of the most popular and important departments of science, literature, and art are also distinctly though briefly explained; and notices are given of their rise, progress, and present state.

Neither must it be supposed that because these articles are for the most part brief and compendious, they are either flimsy or superficial. On the contrary, they have been compiled throughout with the greatest care. Popularity has not been sought for at the expense of science, nor brevity by the sacrifice of useful facts or appropriate illustrations. The work contains not a few new and original views; and it is confidently believed that in every department it will be found to embody the latest information, and to be on a level with the most advanced state to which knowledge has attained, not merely in this but also in other countries. No statement has been made as to any unusual or doubtful matter, without referring to the authority whence it has been derived; and when subjects of general interest and importance are noticed, the reader is referred to the works relating to them in which they are handled with the greatest ability. Not only, therefore, will those who may consult this work have a guarantee for the authenticity of its information, but they will learn the sources to which they may resort with the greatest advantage, should they wish to make farther inquiries.

Such, in a few words, is the design of this work; and, unless its publishers be greatly deceived as to its execution, it can hardly fail to be useful to individuals of all ranks and conditions — to the man of business, and the man of pleasure, the student and the superficial reader, the busy and the idle. Every one who takes any share in conversation, or who dips, how cursorily soever, into any newspaper or other publication, will every now and then find the advantage of having access to the Dictionary of Science, Literature, and Art.

In finally submitting the work to the judgment of the public, the publishers may, perhaps, be allowed to say that they have left no means untried that appeared likely to insure the accuracy and excellence of the work. It was distributed into divisions or departments, each embracing a single subject,

or a class of closely allied subjects; and these were respectively assigned to gentlemen distinguished by their attention to, and proficiency in, the topics to be treated of. This seemed the most likely means to avoid mere compilation; to insure accuracy and adequate information; and to make the work not only a comprehensive and correct, but in some measure also an original, digest and synopsis of human knowledge.

List of the principal Authors of the work, with the departments for which they are respectively responsible.

GENERAL EDITOR,

W. T. BRANDE, F.R.S.L. & E.

Of Her Majesty's Mint; Professor of Chemistry in the Royal Institution of Great Britain; Prof. of Chemistry and Materia Medica to the Apothecaries' Company, &c.

Assisted by JOSEPH CAUVIN, Esq.

1. ARCHITECTURE, MUSIC, AND THE FINE ARTS	JOSEPH GWILT, F. S. A. & F. R. A. S.
2. BOTANY	J. LINDLEY, PH.D. F.R.S. L.S. &c. Professor of Botany in University College, and in the Royal Institution.
3. CHEMISTRY, GEOLOGY, MINERALOGY, MEDICINE, AND THE ARTS AND SCIENCES DEPENDING ON CHEMICAL PRINCIPLES	W. T. BRANDE, ESQ. (Editor).
4. GARDENING AND AGRICULTURE	J. C. LOUDON, F. L. S. H. S. &c.
5. LAW	HERMAN MERIVALE, A. M. Late Fellow of Baliol College.
6. GENERAL LITERATURE	J. R. M'CULLOCH, ESQ., AND JOSEPH CAUVIN, ESQ.
7. MATHEMATICS, AND THE ARTS AND SCIENCES DEPENDING ON MATHEMATICAL PRINCIPLES	THOS. GALLOWAY, M. A. F. R. S.
8. NAUTICAL SCIENCE	LIEUTENANT RAPER, R. N. &c.
9. POLITICAL ECONOMY AND STATISTICS	J. R. M'CULLOCH, ESQ.
10. THEOLOGY	THE REV. CHAS. MERIVALE, M. A.
11. ZOOLOGY, ANATOMY, AND PHYSIOLOGY	RICHARD OWEN, F. R. S. &c.

A

DICTIONARY

OF

SCIENCE, LITERATURE, AND ART.

A. The first letter of the Alphabet, in all known languages, with the exception of the Amaric, a dialect of the Ethiopian, in which it is the 13th, and of the Runic, in which it is the 10th. It was called *Alpha* by the Greeks, and *Aleph* by the Hebrews.

ABACI'SCUS (*see* ABACUS). In Architecture, any flat member. The square compartment of a mosaic pavement.

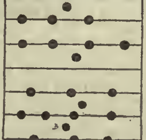
ABA'CK, in sea language, denotes the position of the sails when flatted against the mast by the force of the wind. This may happen either by a sudden change of the wind, or an alteration of the ship's course; or the sails may be *laid aback* for the purpose of avoiding some imminent danger.

A'BACOT. A cap of state worn by the old English kings.

A'BACUS. (Gr. αϐαξ, *a slab.*) In Architecture, the upper part or crowning member of the capital of a column. This member alone seems to have constituted the primitive capital. It is an essential and constituent part of the capital. In the Tuscan, Doric, and Ionic orders it is square, and in the Corinthian and composite curved inwards on its plane and truncated at the quoins or angles at 45 degrees with the face of the entablature. The use of the abacus is to give breadth to the top of the column, and present a larger surface of level bed for the reception of the architrave.

ABACUS. An ancient instrument used for assisting numerical calculations. This term has been variously derived; from the Greek word, *abax*, signifying a table; a Phœnician word, *abak*, signifying sand (because when covered with sand it served for the purposes of writing); but its derivation is most probably to be referred to the three first letters of the Greek alphabet.

The use of the abacus will be readily understood from the annexed figure. A parallelogram is divided by parallel bars, on which small pebbles or counters are placed. The counters on the lowest bar denote units, those on the second tens, those on the third hundreds, and so on; one counter on a superior bar being equal to ten on the bar immediately below it. By means of nine counters for each bar, it is obvious that any number may be thus expressed. But the number of counters may be diminished by placing a counter on the intermediate space between two bars, giving it the value of five on the bar below. When seven bars are used, any number may be expressed under ten millions. The number represented in the figure is 845,398. It will be observed that the artificial value given to the counters, according to the positions which they occupy, is entirely analogous to our numerical system of digits. The form of the instrument admitted of considerable variety. The Grecian abacus was an oblong frame, having wires stretched across it, strung with perforated beads or little ivory balls. In the Roman abacus the counters were slid along grooves. Its use formed an essential part of the education of every noble Roman youth: —



> Nec qui *abaco numeros, et secto in pulvere metas,*
> Scit risisse vafer —— *Pers. Sat.* I. 132.

The Chinese, like the Greeks, employ wires with beads; and with them the abacus or Swan-pan is in universal use, as it conveniently adapts itself to their decimal divisions of weights and measures. The abacus continued to be used in European countries during the middle ages. Instead of a board, however, with bars or wires, it became the practice to cover a bench or *bank* with chequered cloth, on which the counters were disposed. Hence our terms exchequer, bankrupt, &c. A chequered board, such as is still sometimes seen as a sign at the doors of public houses, was formerly used in this country as an abacus. For an excellent account of the abacus, and of palpable arithmetic generally, see the article on Arithmetic, in the Supplement to the Encyclopædia Britannica, by Sir John Leslie.

ABA'FT, or AFT, in sea language, signifies towards the stern, or hinder part of the vessel. Thus a thing is abaft the foremast when it is between the foremast and the stern.

ABA'NDONMENT. A term used in insurances, where, before compensation can be demanded, the insurer must abandon his interest in any portion of the rescued property. It is also used in the language of the customs, to signify the abandonment of an article by the importer to avoid payment of the duty.

ABA'TEMENT, Plea of, in Law, is pleaded to a declaration, writ, &c., on account of some defect in form. (*See* PLEADING.)

ABATEMENT. In Heraldry, symbols of disgrace introduced into arms: mentioned for the most part only by English heraldic writers. A *delf*, or *quadrant* spot, is the sign of a revoked challenge: an *escutcheon reversed*, belongs to an ungallant person or deserter: a *point dexter parted*, to a boaster: a *point in point*, to a coward: a *point champain*, to one who kills a prisoner of war: a *gore sinister*, to effeminate persons: a *gusset dexter* denotes voluptuousness, a *gusset sinister* intoxication. The only abatement now used in practice is the *baston*, which belongs to bastards; it is in the form of the bend sinister, contains one fourth of its dimensions, but does not reach quite to the circumference of the escutcheon.

A'BATIS. (Fr. abattre, *to knock down.*) A military term, signifying trees cut down, and laid with their branches towards the enemy, so as to form a defence for troops stationed behind them. *Abatis*, among the writers of the barbarous ages, denotes an officer in the stables, who had the care and distribution of the provender.

A'BATON. (Gr. αϐατον, *an inaccessible place.*) An edifice at Rhodes so called by Vitruvius, lib. 2., the

entrance whereof was forbidden to all persons, because it contained a trophy and two bronze statues erected by Artemisia in memory of her triumph on surprising the city.

ABATTOIR. (Fr. abattre, *to knock down.*) A building appropriated to the slaughtering of cattle. In Great Britain we have no example of such a structure, our slaughter-houses not deserving the appellation as applied by the French. Paris possesses some fine specimens of this sort of architecture, constructed in 1809; the most magnificent is that in the neighbourhood of Montmartre.

ABBE′. The French term for the superior of an abbey. Before the Revolution the title was assumed also by a class of persons who had not in all cases received the tonsure, or undertaken to connect themselves with the church. They held a conspicuous place in society, and generally attached themselves to fashionable or literary patrons. This anomalous class seems to have taken its rise from the great number of abbeys, the revenues of which were allowed to be bestowed upon laymen, upon condition of their taking orders within a year after their preferment, which latter clause was frequently evaded.

A′BBESS. (Fr. *Abbesse.*) The governess or superior of a monastery or abbey for females. By a decree of the Council of Trent she must be of the age of forty years, and have professed eight years at least.

A′BBEY. (Fr. *Abbaïe.*) In Architecture, properly, the building adjoining or near a convent or monastery, for the residence of the head of the house, abbot or abbess. It is often used for the church attached to the establishment. In ecclesiastical history an Abbey was a monastery under the superintendence cf on abbot, maintaining in later times the highest rank among religious houses, and enjoying some superior privileges.

A′BBOT. The superior of a monastery for men. Monastic societies, being originally composed of laymen, were obliged to have recourse to the assistance of a neighbouring priest to administer the sacraments and perform other clerical functions among them. Afterwards the superior of the society in many cases entered into orders, and exercised the ministerial office for the convenience of his community, under the title of abbot. (Heb. abba, *father.*) From the beginning of the sixth century this practice became universal, the abbot having absolute power within his own monastery, but being himself subject to the authority of his diocesan. This subjection, however, the abbots gradually threw off to a great extent, and in many places themselves assumed the titles and authority of bishops. Such were the mitred abbots, and the crosiered abbots; the former of whom, to the number of 26, sat in the English parliament with the bishops and two priors in the reign of Henry VIII.

Abbots are properly superior in rank to Priors; the latter being often appointed by the abbot to superintend a dependent foundation. But the distinction does not appear to have been regularly observed, and there are certain orders whose superiors are always called priors; —as the monks of Vallombrosa, the Cistercians, Bernardists, Feuillants, Trappists, Grandmontanists, and Præmonstratenses.

ABBREVIA′TION. (Lat. brevis, *short.*) In Arithmetic. The process by which a fraction is reduced to lower terms; thus the division of the numerator and denominator of $\frac{16}{24}$ by 8 reduces or abbreviates the fraction to $\frac{2}{3}$.

ABBREVIATION. In Music. A stroke which, placed over or under a note, divides it into quavers if there be only one; if two, into semiquavers; if three, into demisemiquavers.

ABBREVIATION. In Writing. Before the invention of printing, a variety of abbreviations were used, most of which have gradually fallen into disuse: they generally consisted in substituting the initials for the words. Of the abbreviations at present in use, the following are those which most commonly occur:—in Titles,

A. M., Master of Arts.	K. C. H., Knight Commander of Hanover.
A. B., Bachelor of Arts.	K. G., Knight of the Garter.
B. C. L., Bachelor of Civil Law.	LL. D., Doctor of Laws.
B. D., Bachelor of Divinity.	M. A., Master of Arts.
Clk., Clerk or Clergyman.	M. D., Doctor of Medicine
C. B., Companion of the Bath.	M. P., Member of Parliament.
D. C. L., Doctor of Civil Law.	M. R. I. A., Member of the Royal Irish Academy.
D. D., Doctor of Divinity.	R. A., Royal Academy.
F. R. S., Fellow of the Royal Society.	R. E., Royal Engineers.
	R. M., Royal Marines.
G. C. B., Grand Cross of the Bath.	R. N., Royal Navy.
G. C. H., Grand Cross of Hanover.	S. T. P., Doctor of Divinity, or Sanctæ Theologiæ Professor.
K. B., Knight of the Bath.	E. I. C., East India Company.
K. C. B., Knight Commander of the Bath.	W. S., Writer to the Signet.

Miscellaneous, Diplomatical, &c.

A. D., the year of our Lord.	A. C. or B. C., the year before Christ.
A. H., the year of the Hegira.	A. U. C., the year from the building of Rome.
A. M., the year of the world.	
i. e., that is to say.	Nem. con., no one contradicting.
ib., in the same place.	
id., the same.	Nem. dis., no one dissenting.
N. B., observe.	M. S., manuscript.
viz., for videlicet, to wit.	A. M., morning.
L. S., (in a deed) the place of the seal.	P. M., afternoon.
	H.M.S., His Majesty's ship, or service.
R. S. and L. S., right and left side.	D. G., by the grace of God.
N. S., new style, (since 1752.)	F.D., Defender of the Faith.
	H. R. E., Holy Roman Empire.
O. S., old style, (before 1752, and in the Greek calendar.)	U. S., United States of America.

ABDICA′TION. (Lat. abdico, *I abdicate.*) In Politics, the renunciation of an office or dignity by its holder; but it is commonly meant to express the voluntary renunciation of supreme power. The most famous examples of this on record, are the abdication of the dictatorship by Sylla, 75 years B. C.; of the imperial throne, by Dioclesian, anno 305; of the emperor Charles V., in 1556; and of Christina, queen of Sweden, in 1654.— Of all the sovereigns who have made voluntary abdications, Dioclesian, is, perhaps, the only one who did not regret the step. Examples of forced or involuntary abdication are too numerous to require to be pointed out. The modern history of France and England furnish some very striking instances with which every one is familiar. The convention parliament of 1688 used the word abdication to express the act of James II. in abandoning the government and kingdom. The word "desertion" was rejected, as implying the possibility of a return. The Scottish convention of estates declared that James had "forfeited" the kingdom. Abdication is said to differ from resignation, the former being unconditional, the latter done in favour of some other person.

ABDO′MEN. (Lat. abdo, *I conceal.*) The great cavity of the animal body, which is liable to temporary changes in its dimensions, independently of respiration. In entomology it forms, in insects the third, in arachnidans the second, in both classes the most posterior, of the sections into which the body is externally divided, and contains the principal digestive and respiratory, and the whole of the generative organs. The enlargements of the abdomen, in relation to the activity of the generative functions, is most remarkable in insects; in some of which, as the white ant, or termite, it constitutes at the full development of the ova an immense proportion of the entire body of the female. In vertebrates the abdomen is not divided externally from the thorax; and only in one class, the mammalia, by an internal partition, or diaphragm.

The abdomen is the first-formed cavity in the development of the animal body, and is the most constant in its existence throughout the animal series. (*See* CRANIUM and THORAX.)

ABDO′MINALS. *Abdominales.* An order of malacopterygious fishes, including those which have the ventral fins situated under the abdomen, behind the pectorals.

ABDU′CTION. (Lat. ab, *from,* and duco, *I lead.*) In Law, the forcible carrying away of a woman, for the purpose of marriage or defilement. Where the female has property, or is presumptively entitled to it, such abduction is felony: and in all cases the taking of a girl under sixteen from under the protection of her parents is a misdemeanour. The crime of abduction, according to Sir W. Scott (see his Notes and Introduction to Rob Roy), was at one period extremely common on the border of the Scottish Highlands; it is now an ordinary offence in Ireland: the number of convictions in the last 7 years amounts to 61; executions, 5.

ABDU′CTOR. Abductor muscles are those which pull back or separate the limbs to which they are affixed.

A′BELITES, or *Abelians,* in ecclesiastical history, a sect mentioned by St. Augustine, in Africa. They are said to have enjoined marriage and virginity, after the pretended example of Abel. (*See* Mosheim, *Eng. Trans.* i.233.)

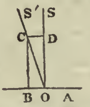
A′BER. A Celtic term, implying the mouth of a river; as Aberdeen, the mouth of the Dee; Aberystwith, the mouth of the Ystwith, &c.

ABE′RDEVINE, or European Siskin; (*Carduelis spinus,* Cuv.) A small green and yellow finch, belonging to the same sub-genus as the goldfinch of this country. Its song is similar to that of the goldfinch, but is not so sweet, and ends with a harsh jarring note. Its flight is a series of successive undulating courses, accompanied by a chirp, at each propelling motion of the wings, as in other species of *Carduelis.* The Aberdevine winters in the south of England, and flies northward in the month of March, to breed in the pine forests of Scotland. The

nest is built among the higher branches of the pine: the eggs are four or five in number; of a bluish-white colour, speckled with purplish-red. They begin to re-appear in the south in the month of September. The Aberdevine resembles in the markings of its plumage the common redpole, (*Linaria pusilla*, Cuv.) but the colours are different.

ABERRA'TION. (Lat. ab, *from*, and erro, *I wander.*) A term used in astronomy, to denote a change in the positions of the celestial bodies arising from the combined effects of the motion of light and the motion of the earth in its orbit.

To explain the cause of this remarkable phenomenon, conceive a ray of light to proceed from a star S to an observer at O. If the station of the observer were at rest, or if the motion of light were instantaneous, the star would be seen in its true place at S. But neither of these circumstances has place; the observer is carried rapidly forward by the motion of the earth in its orbit, and light occupies a certain time in coming from any of the heavenly bodies to the earth.



Suppose, then, that while a particle of light advances from D to O, the observer has been carried forward by the earth's orbital motion from A to O. At O the particles of light will strike the eye with a velocity proportional to D O, and the eye will impinge against the particle with a velocity proportional to A O. Thus a double effect will be produced: first, that of the motion of light proportional to D O, and, secondly, that arising from the motion of the observer proportional to A O. But it is obvious that the question will in no way be affected if we suppose that, instead of the observer having been carried forward from A to O, he had remained at rest in O, and the light had advanced to him in the opposite direction, and with a velocity B O = A O. Thus the eye would receive two simultaneous impressions in the directions D O and B O of the parallelogram B C D O; and by the theory of the composition of velocities the effect would be exactly the same as if the eye had received a single impression from a particle proceeding in the direction of the diagonal C O, and with a velocity proportional to C O. Hence the apparent place of the star will be at S′, in advance of its true place at S.

The angle C O D is the *aberration*, and its magnitude can easily be determined when we know the relative magnitudes of D O and B O, and the inclination of those lines; that is, when we know the relative velocities of light and of the earth, and the relative direction of their motions. It is obvious that the aberration will be greatest when those lines are perpendicular to each other; when they are parallel it vanishes altogether.

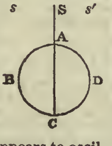
From the eclipses of Jupiter's satellites, and other phenomena, it has been ascertained that light is transmitted through space with a velocity of 192,000 miles per second. The mean velocity of the earth in its orbit is about 19 miles per second; we have, therefore, when B O and D O are at right angles, the proportion

$$192{,}000 : 19 = \mathrm{D\,O} : \mathrm{B\,O} = \text{rad.} : \text{tan. } \mathrm{C\,O\,D};$$

hence the tangent of C O D, or the aberration (or in so small an angle the tangent is equal to the arc), is found by the Trigonometrical Tables = 20″·5. This being the greatest value of the angle, is called the *Constant of Aberration.*

From Bradley's observations the Constant of Aberration was determined by Bessel (*Fundamenta Astronomiæ*) to be 20″·25. Dr. Brinkley found it = 20″·37. Mr. Richardson, from a series of 2000 observations made with the two mural circles in the Greenwich Observatory, found the value of this important element = 20″·307. (*Memoirs Royal Astr. Society*, vol. iv.)

The effect of aberration on any particular star depends on the position of the star with reference to the ecliptic. Let A B C D be the orbit of the earth, and S a star in the plane of the ecliptic. When the earth is at A the star will be thrown forward by the effect of aberration to *s*. When the earth arrives at the opposite point of its orbit C, the star will be thrown back to *s′*. At B and D the earth is moving in a direction parallel to the ray of light proceeding from the star, and there is, consequently, no aberration.



Hence a star situated in the plane of the ecliptic appears to oscillate backwards and forwards in a straight line, always returning to its former position at the end of a year.

A ray of light proceeding from a star situated in the pole of the ecliptic, is always at right angles to the direction of the earth's motion; consequently, a star having this position will appear to describe annually, about the pole of the ecliptic, a circle of which the radius = 20″·3.

In any other position the apparent path of a star, so far as depends on aberration, is an ellipse whose major axis = 40″·6, and its minor axis = 40″·6, multiplied by the sine of the star's latitude.

The apparent places of the planets are also affected by aberration; but in this case, as the body from which the light emanates is also in motion, we must consider that the ray of light which enters the eye has proceeded, not from the place which the planet occupies at the instant of the observation, but from that which it did occupy at as long an interval previously as light requires to traverse the distance between the planet and the earth. To this small variation in the place of the planet must be added the space described by the earth in the same interval; and it is easy to see that the sum is the apparent or relative motion of the planet during the time which light takes to pass from it to the earth.

The aberration was discovered, and its physical cause first explained, by Dr. Bradley. It is the most direct proof which astronomy furnishes of the motion of the earth round the sun.

ABERRATION. In *Optics*, denotes the deviation of the rays of light from the true focus of a curved lens or speculum; in consequence of which they do not unite in a single point, but are spread over on a small surface, and form a somewhat confused image of the object. This arises from two causes: 1st, the figures of the lenses or specula; and, 2dly, from a difference in the physical nature of the rays of light.

The surfaces of the lenses or mirrors of optical instruments are worked into a spherical form, because there is no practical means of accurately obtaining the parabolic curvature which theory shows to be necessary to collect parallel rays into a single point or focus. Hence the rays meet the axis of the lens at different points, the amount of deviation depending on the magnitude and curvature of the lens. This is called the *Aberration of Sphericity.* The second cause of aberration arises from the different degrees of refraction which the rays composing a beam of light undergo in passing from one medium into another. On account of this difference of refrangibility, the rays of light are separated, and the colours of the spectrum appear. It was long believed, and even by Newton himself, that it was impossible to refract, without decomposing, light; and hence the attempts that have been made to perfect reflecting telescopes, and adapt them to circular instruments. But it has since been discovered that the refractive and dispersive powers of different diaphanous substances are in different proportions, and that the decomposition of the light may be prevented by combining substances of different refractive powers; for example, crown and flint glass, in the same lens. (*See* ACHROMATISM.)

ABE'TTOR. (Sax. abedan, *to incite*,) In *law.* An instigator or incitor; a person who promotes or procures the commission of an offence or felony, by his advice or encouragement. If an abettor, or as he is then termed, an aider and abettor, be present at the commission of the crime, he is treated as a principal; if absent, he becomes an *accessory* before the fact. But in almost all cases of felony the abettor is considered as much a principal as the actual felon, especially in the case of murder; and the abettors of offences punishable summarily by justices of the peace, are subjected to the same penalties as the principals.

ABE'YANCE. (Norm. Fr. beyer, *to expect.*) In *law.* The fee simple, or inheritance of lands is said to be in abeyance, when there is no person *in esse* in whom it can vest and abide, although limited and ready to vest whenever the proper heir appears. Thus, in a grant to A for life, and afterwards to the heirs of B, the inheritance remains in abeyance until the death of B, as there can be no heir to a living person. A peerage descending to coheiresses is said to be in abeyance.

A'BIB. The first month of the Hebrew year, more generally known by the Chaldean name of *Nisan.* It is first mentioned in the 4th verse of the 13th chapter of Exodus.

A'BIES. (Lat. abies, *a fir tree.*) The name of all those fir trees which, like the spruce, the larch, the cedar of Lebanon, have their leaves growing singly upon the stem, and the scales of the cones round and thin. The wood called by timber-merchants "white deal" is produced by Abies excelsa, and a resinous, or terebintaceous substance by others; as Canadian balsam by A. balsamea, the balm of Gilead; Strasburgh turpentine by A. pectinata, the silver fir; Venetian turpentine by A. larix, the larch. Besides these, the substance called extract of spruce is furnished partly by A. canadensis, and partly by A. nigra. All the species are hardy, and, with the exception of larches, are evergreen, and in cultivation in this country. The most valuable for the timber are, A. Douglasii, A. excelsa, and A. larix; the most ornamental are, A. cedrus, the cedar of Lebanon, deodara, and larix. The most worthless in Great Britain are, A. canadensis, picea, balsamea, and pectinata; the three latter form, however, fine trees in favourable situations. The wood of the fir is in very extensive use, and it is, perhaps, the most serviceable of all trees.

ABIETI'NÆ. A division in the natural order of coniferous plants, comprehending the true firs, pines, and

araucaria-like pines, all which have cones with many rows of scales in which the seeds are formed.

ABJURA'TION, *Oath of.* (Lat. ab. *from*, and juro, *I swear.*) Introduced by stat. 13 W. III., and regulated by 6 G. III. An oath asserting the title of the present royal family to the crown of England. By this oath the juror recognises the right of the king under the Act of Settlement; engages to support him to the utmost of his power; promises to disclose all traitorous conspiracies against him; and expressly disclaims any right to the crown of England in the descendants of the Pretender.

Abjuration *of the Realm* (in law) signifies a sworn banishment; or the taking of an oath to renounce and depart from the realm for ever.

Abjuration also signifies a solemn recantation of opinion: as, the abjuration of heresy required by the Romish Church. Henry IV. abjured Protestantism at Saint Denis in 1593. Galileo was compelled to abjure his philosophical opinions by the Inquisition at Rome, in 1633.

A'BLATIVE *case.* (Lat. ablatus, *taken away.*) The sixth case of the Latin nouns implied in English by the preposition *from.* (See Grammar.)

A'BLU'TION. (Lat. ablutio, *washing.*) A religious ceremony, consisting in bathing the body, or part of it. It constituted a part of the Mosaic ceremonial, and was afterwards practised among the Jews, both by the priests and people. But ablutions are most rigidly enforced by the Mahometans. The term is also applied to the cup given, without consecration, to the laity in the popish churches.

ABNO'RMAL. (Lat. ab, *from*, and norma, *a rule.*) Any thing without, or contrary to, system or rule. Thus Horace calls a well-informed sagacious countryman, —

Rusticus, abnormis sapiens, crassâque Minervâ.

In *botany*, if a flower has five petals, the rule is that it should have the same number of stamens, or some regular multiple of that number; if it has only four or six stamens, then, in such a case, the flower would be abnormal.

ABOA'RD, within the ship; also one vessel is said to get aboard of another when she gets foul of her.

ABORI'GINES. The first, or original (*a prima origine*) inhabitants of a country, that is, those who occupied it at the period when it began to be known, and who either were indigenous to the soil or had immigrated thither before the dawn of history. Some of the ancients supposed they had always inhabited the same soil, and were created from it, as the Athenians, who thence called themselves *autochthones*, coeval with and sprung from the land. But the Romans and modern nations use the word Aborigines to designate those inhabitants of a country of whose origin nothing certain is known. Thus the Indians of America are properly called Aborigines, because they were found there at its discovery, and we have no accounts of their having immigrated from any other quarter.

ABO'RTION. (Lat. abortus, *miscarriage.*) This term is usually applied to the morbid or unnatural expulsion of the fœtus in the human subject after the sixth week, and before the sixth month, of pregnancy. Before the sixth week it is called a *miscarriage*, and after the sixth month, *premature labour.*

ABO'RTIVE. Is said of parts in plants that do not acquire their usual state of perfection; a flower only partially formed, a stamen whose filament has no anther, a seed which contains no embryo, or which consists only of skin, are cases of abortion. The term is also applied to parts which, although perfect in the beginning, cease to grow, and so end in being imperfect; thus ovules, which are not impregnated, and which shrivel up instead of growing into seed, are called abortive.

ABO'UHANNES. An African bird, supposed to be the Ibis of the ancients.

ABRACADA'BRA. A celebrated term of incantation: especially used as a spell against fevers. The manner in which it was written and carried for that purpose may be seen in Defoe's History of the Plague at London. The word seems to be connected with *Abrasax* or *Abraxas*; a name found inscribed on certain stones or amulets, in such characters, together with the figure of a human body, with the head of a cat and feet of a reptile. Various explanations have been attempted of the object of these curiosities: some from the cabalistic and an Egyptian derivation. Bellermann (Berlin, 1817,) and Neander, have written on the subject of the Abraxas stones.

ABRA'DING. In Agr. (Lat. ab, *from*, and rado, *I scrape or rub off.*) Applied to the sloping surface of banks of earth, which crumbles down from the effects of frost, or the alternate action of drought and moisture.

ABRA'MIS. (*Abramis*, Cuv.) The name of a subgenus of Malacopterygious or soft-finned abdominal fishes, characterized by the absence of spines and barbels; by the dorsal fin being short and placed behind the ventrals, and the anal fin being long. The common bream is a species of this genus.

ABRA'NCHIANS. *Abranchia*, Cuv. (Gr. α, *without*, βραγχια, *gills.*) An order (the third in Cuvier's arrangement) of anellidans, so called because the species composing it have no external organs of respiration; they are divided into the setigerous abranchians, or worms, and the non-setigerous abranchians, or leeches.

ABRA'SION. (Lat. abrado, *I rub off.*) In Numismatology, implies the waste of coins, or the loss by wear and tear in the pocket. This forms a considerable item in the expense of a metallic currency; and various means have been employed to lessen it, by alloying the coins so as to render them harder, by raising the borders so as to lessen the surface exposed to be rubbed, &c.

ABRA'XAS. A genus of Lepidopterous insects, of the family Geometridæ; founded by Dr. Leach for the common magpie moth (*Abraxas glossulariata*) and other allied species. It is the larvæ of the *Abr. glossulariata* which commit the well-known ravages upon the gooseberry trees of our gardens; consuming the leaves almost as soon as they appear. They feed early in the morning, before the dew is off or the sun has much power; and it is at this time that they should be sought for and removed.

ABRI'DGEMENT. In Literature. (Lat. abbrevio, *I shorten.*) A compendious arrangement of the matter contained in a larger work. Before the invention of printing, when manuscripts were valuable, and the labour of writing them great, the compiling abridgements of considerable works was an important branch of authorship; and it has been doubted whether we have lost or gained more by the practice: since, on the one hand, the contents of many lost authors are thus partially preserved to us: and, on the other, the abridgement becoming popular may, in some cases, have caused the loss of the original. Among the best known abridgements of antiquity are the History of Justin, being an abridgement of the lost History of Trogus Pompeius: the Natural History of Solinus, chiefly abridged from that of Pliny, &c. Few modern abridgements, taking the phrase in its strict sense, merit peculiar notice, or have been compiled with any other view than that of assisting education. This, however, is not the case with some of those works called abridgements, intended to exhibit a summary view of some science or department of literature. The *Abrégé Chronologique de l'Histoire de France*, by the president Henault, is a work of this kind. It has, perhaps, been praised beyond its deserts, but still it possesses uncommon merit. Its success led to the publication of various works of the same kind, of which the *Abrégé Chronologique de l'Histoire de l'Allemagne*, by Pfeffel, is probably the best. Dr. Robertson drew from it most of his knowledge of the constitution of the German empire. To abridge well requires a thorough knowledge of the subject, with tact to seize upon the prominent points, and ability to state them clearly and succinctly. Tacitus, says Montesquieu, "*abridged all because he knew all*," but Tacitus's are rare.

ABROGA'TION. The annulment of a law by competent authority. (From the Latin ab, *from*, and rogo, *I ask.*) A phrase derived from the practice of the Roman popular assemblies, in which the several tribes, curiæ, &c. were said rogare suffragia, to demand the suffrage: whence also the modern word *prerogative.* (*See* Comitia.)

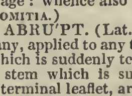
ABRU'PT. (Lat. abrumpo, *I break off.*) A term in Botany, applied to any thing which happens suddenly. A leaf which is suddenly terminated without tapering to a point, a stem which is suddenly bent, a pinnated leaf without a terminal leaflet, are all abrupt.

Abrupt. In Ichthyology is applied to the lateral line when divided into two or more parts not contiguous.

A'BRUS. (Gr. ἁβρὸς, *delicate*, or *elegant.*) A West Indian tree with papilionaceous flowers, and pods containing bright red seeds with a broad black scar on one side of them. The seeds are often strung into necklaces for children.

A'BSCESS. (Lat. abscedo, *I separate.*) Inflammation in the membranous or fleshy parts of the body, attended by the formation of *pus*, and the consequent separation or distension of the parts affected; thus the integuments separate from the parts beneath, and form a tumour.

A'BSCISS, or ABSCISSA. (Lat. ab scindo, *I cut off.*) A term used in geometry to denote a segment cut off from a straight line, by an ordinate to a curve. The position of a point on a plane is perfectly determined when its distances, measured in given directions, from two straight lines given by position, are known; and as curve lines may be regarded as formed by the continuous motion of a point, their various properties may be investigated by means of the relation common to all points of the same curve between the two distances so measured. Thus, let A B and A C be two straight lines given by position, and P any point in a curve X Y. Draw P Q parallel to A C, and meeting A B in Q, then P Q is called the ordinate of the point P, and A Q is the *absciss.* The absciss and ordinate, considered together, are called the co-ordinates



of the curve, and the point A, where they intersect, is called the origin of the co-ordinates. For every point of the same curve a certain unavoidable relation exists between A Q and P Q, which is called the equation of the curve. In order to represent this equation algebraically, the absciss A Q is represented by x, and the ordinate P Q by y. The co-ordinates may be inclined to each other at any angle, but in general the investigations are much simplified by assuming them at right angles. The origin of the co-ordinates, or the point from which the absciss is reckoned, may be taken any where in the plane of the curve. When a particular curve, however, is to be investigated, it is often convenient to place the origin at some point which is related to the other parts of the curve. Thus, if the curve is a circle, the co-ordinates are conveniently reckoned from the centre.

ABSENTE'E. In Politics, a word which has received, from usage, a peculiar signification: a landed proprietor who habitually resides at a distance from the district in which his property is situate: especially applied to Irish landlords and clergy. In 1715 a tax was imposed on absentees from Ireland, in all cases where their residence within it was for less than six months in the year; power of dispensation being secured to the crown. But it ceased to be levied in 1753, and has not since been renewed. Whether or not the absence of a landed proprietor be injurious to a country, in an economical sense, is a question which has been much debated of late years. See the evidence of Mr. J. R. M'Culloch before the Committees of the Lords and Commons, to inquire into the state of Ireland, 1825; and the controversy occasioned by that evidence, in the Edinburgh Review, No. 85., and Quarterly Review, Vol. 33. See also Mr. M'C.'s evidence before the Committee on the state of Ireland in 1830, and Mr. Senior's Outline of Political Economy, Encyclopædia Metropolitana.

A'BSIS, or APSIS. (Gr. ἁψις, *an arch.*) In Architecture, a word used by ecclesiastical authors to signify that part of the church wherein the clergy were seated, or the altar was placed. This part of the church was so called from its usually being domed or vaulted, and not, as Isidorus imagines, from its being the lightest part, from *apta*. The apsis was either circular or polygonal on the plan, and domed over at top as a covering. It consisted of two parts, the altar and the presbytery, or sanctuary; at the middle of the semicircle was the throne of the bishop; and at the centre of the diameter was placed the altar, towards the nave, from which it was separated by an open balustrade, or railing. On the altar was placed the cibarium and cup. The throne of the bishop having been anciently called by this name (apsis), some have thought that thence this part of the edifice derived its name, but the converse is the real truth.

A'BSOLUTE. ABSOLUTISM. In Politics, a government is strictly said to be absolute when the supreme head is above the control of law, and has unrestricted power of legislation. "El rey assoluto," is the common watchword of the anti-constitutional party in Spain. Yet in that country, as in almost every other, the theory of absolute sovereignty has some limit: since we find the same party denying the king the right of altering by his single will the fundamental laws of succession to the throne. (*See* DESPOTISM.)

ABSOLU'TION. (Lat. ab, *from*, solvo, *I loose.*) A ceremony practised in various Christian churches. In the Roman Catholic, the priest not only declares absolution to the repentant sinner, but is believed to have the power of actually releasing him from his sins: and this authority is declared by the council of Trent to belong to him in its full extent. The Church of England, in the Order for the Visitation of the Sick, has retained nearly the same words; but her authorities seem not to be exactly agreed as to the force and effect of the absolution so conferred. In the daily service, the words of the absolution are merely declaratory.

ABSO'RBED. (Lat. absorbeo, *I suck up.*) In Painting. Sucked up, imbibed. A term applied by the French connoisseurs to a picture in which the oil has sunk into the canvass or ground whereon it is painted, leaving the colour flat, and the touches indistinct. Our picture dealers used the term *chilled* to express the same thing. It may be remedied by rubbing the picture over with oil, and varnishing, after it has been well cleaned.

ABSO'RBENT *Ground*. In Painting. A ground prepared for a picture, either on board or canvass, chiefly with distemper or water-colour mixture, by which expedient the oil is immediately taken or sucked in from the colours, expedition gained, and a brilliancy imparted to the colours.

ABSORBENTS. In Medicine, substances which remove acid at the stomach, such as magnesia and chalk.

ABSO'RPTION. In Physiology, is one of the vital organic functions, the object of which is primarily to convey to the circulating organs the due supply of the materials for the growth and support of the system; and, secondarily, to remove and carry to the same organs the decayed and useless parts of the body. *See* LACTEALS.

A'BSTRACT (Lat. abstraho, *I take away*), signifies a general view or analysis of a whole work, or part of a work. It differs from *abridgment* chiefly in this, that while in the latter it is often necessary to enter into somewhat minute details, the former is always confined to a notice only of the leading particulars. *See* ABRIDGMENT.

A'BSTRACT MATHEMATICS, or PURE MATHEMATICS. That branch of science which treats of the relations or properties of magnitudes or quantities, considered generally, and without restriction to any individual magnitude. Thus, the proposition that the three angles of a triangle are, together, equal to two right angles, is an abstract truth, not confined to an individual triangle, or to a particular species of triangles, but belonging to all triangles whatever. Abstract mathematics is opposed to *mixed mathematics*, wherein abstract properties or relations are applied to sensible objects.

ABSTRACT NUMBERS. Numbers considered in themselves, and without reference to any particular thing. The operations of common arithmetic are performed on abstract numbers.

ABSTRA'CTION. (Lat. abstraho, *I draw off.*) In Metaphysics and Logic, the faculty by which, in contemplating any object, we can attend exclusively to some circumstances or qualities belonging to it, and withhold our attention from the rest. It is by the means of this faculty that we generalise, and arrive at the common terms or predicables (*see* PREDICABLES) which belong to a number of objects. Thus, in considering a horse, by abstracting mentally the qualities which belong to that particular animal, we arrive at the notion of a quadruped, thence at that of an animal, &c. &c.; which notions constitute, in logical language, the successive genera and species of the individual horse.

ABSU'RDUM, or REDUCTIO AD ABSURDUM. A term used in geometry to denote a mode of demonstration in which the truth of a proposition is established, not by a direct proof, but by proving that the contrary is *absurd*, or impossible. There are many examples of this mode of demonstration in the Elements of Euclid.

ABU'NDANT NUMBER (Arithmetic) is a number such that the sum of its divisors is greater than the number itself. Thus, 12 is an abundant number, because its divisors being 1, 2, 3, 4, and 6, their sum, which is 16, is greater than 12. An abundant number is opposed to a *deficient* number, of which the sum of the divisors is less than the number itself; and to a *perfect* number, of which the sum of the divisors is equal to itself.

ABU'TMENT. (According to some, from the French, aboutir, *to abut*, among whom the learned Spelman; but according to others, with more probability, from the Saxon abutan, *about.*) In Architecture, the solid part of a pier from which the arch immediately springs. Abutments are either artificial or natural. The former are usually formed of masonry or brickwork, and the latter are the rock or other solid materials on the banks of a river, in the case of a bridge, which receive the foot of the arch. It is obvious that they must be of sufficient solidity and strength to resist the arch's thrust.

ABU'TTALS. The buttings or boundings of land, showing by what other lands, highways, rivers, &c. they are bounded.

ACA'CIA. (Gr. ακακια.) A genus of spiny leguminous trees, with pinnated leaves, and small flowers collected in balls or spikes, of a white, red, or yellow colour. They are all inhabitants of the warmer parts of the world; some of them, as A. vera, arabica, &c., yield gum arabic; others gum senegal: the bark of A. catechu furnishes the astringent substance called catechu, or terra japonica. The flowers of A. farnesiana are exceedingly fragrant, and form one of the principal ingredients in Italian perfumery. The bark of many species abounds in tanning principles. New Holland, and some other countries, produce great number of species in which true leaves are not formed, but in their stead the branches are furnished with broad dilated petioles looking like leaves.

ACADE'MICS. A name given to a series of philosophers, who taught in the Athenian Academy, the scene of Plato's discourses. They are commonly divided into three sects, which go under the names of the Old, the Middle, and the New Academy. 1. The Old Academy, of which Plato was the immediate founder, was represented successively by Speusippus, Xenocrates, and Polemo. These philosophers, as far as the scanty notices remaining of them allow us to form a judgment, seem to have confined themselves to the task of elucidating and defending the doctrines of their great master. (*See* PLATONISM.) A list of their works is given us by Diogenes Laertius, b. iv. To them succeeded Arcesilaus, the founder of (2) the Middle Academy. Under his hands, the Platonic method assumes an almost exclusively polemical character. Whatever may have been his belief regarding the positive part of Plato's doctrines, he confined himself in public to the support of the negative portion; that, namely, which relates to the uncertainty

of the impressions on the senses, and, consequently, of the judgments founded on them. His main object was to refute the Stoics, who maintained a doctrine of perception identical with that promulgated by Dr. Reid in the last century. (*See* PERCEPTION.) Socrates is said to have professed, that all he knew was, that he knew nothing. Arcesilaus denied that he knew even this. Wisdom he made to consist in absolute suspension of assent; virtue, in the probable estimate of consequences; in the latter doctrine combating the ethical dogmatism of the stoics, as in the former the intellectual. He was succeeded by Lacydes, Telecles and Evander, and Hegesinus. 3. The New Academy claims Carneades as its founder. It is not easy to define the limits between this and the Middle Academy. Like Arcesilaus, Carneades appears to have taken up a negative and polemical position. His system is a species of mitigated scepticism. He considers probability to be the sole legitimate object, alike in speculation and in practice. The doctrines of this school were adopted by Cicero, more, probably, in consequence of the advantage which, as an orator, he would derive from the practice of discussing both sides of a question, than from any solid conviction. Carneades was succeeded by his disciple, Clitomachus. Charmides, the third and last of the New Academicians, appears to have been little more than a teacher of rhetoric: an accusation, indeed, to which the whole school is in no small degree liable. To these three academies a fourth and fifth are added, by some writers: of which Philon and Antiochus are produced as the representatives. The latter was the friend of Cicero and other distinguished Romans. Neither of them can in any justice be named academics, their doctrines being, in fact, in most points, of a diametrically opposite nature.

ACA′DEMY. (Gr. ἀκαδημια.) A society of learned men, associated for the advancement of the arts or sciences. The name is derived from that of a place near Athens, where there was a famous school for gymnastic exercises (*see* GYMNASIUM), at which also philosophy was taught, and the sophists gave their lectures. But the first institution of which we read, at all resembling our modern academy, was the society of scholars established at Alexandria by Ptolemy Soter. The Jews in various cities, the Constantinopolitan emperors, and the Arab caliphs, founded societies of the same description. Charlemagne, among his various efforts for the propagation of literature, collected an association of learned men, who read and compared the works of antiquity, and gave themselves, in their academic intercourse, the assumed names of different ancient authors. But this institution was dissolved at the death of Alcuin; nor do we find any memorial of a similar society, except a few among artists, chiefly in France, until after the taking of Constantinople by the Turks, when the Greek scholars driven into Italy held literary meetings, which gradually assumed a more regular form. About 1560 a society, called the Academia Secretorum Naturæ, was founded at Naples, in the house of Baptista Porta, but was abolished by a papal interdict. It was, however, succeeded by the Academia Lyncei at Rome, of which Galileo was a member, the objects of which, like those of the former, were chiefly connected with the pursuit of natural history. From the beginning of the 17th century academies multiplied in Italy. Among the most eminent of those which bore a philosophical character, was the A. del Cimento, at Rome, in that century; the Academy of Orossano, in the kingdom of Naples, &c.: and, in more recent times, the Academy of Sciences at Bologna deserves to be mentioned with honour. But Italy has been most prolific in academies of literature and philology, which form by far the greatest number in the catalogue of 550 such institutions which have been enumerated as existing or having existed in that country. A general and somewhat ridiculous fashion prevailed in the 17th and 18th centuries among literary men of that country, of forming themselves into societies for the promotion of literary objects, to which they gave fanciful symbolic names, every member assuming in his own person some analogous appellation. Some of these societies have done real service to literature, but by far the greatest number have contented themselves with multiplying insipid addresses and sonnets. Among the most celebrated was the A. degli Arcadj, at Rome, of which the meetings were held in a meadow, and the members enacted shepherds and shepherdesses: it was founded about 1690, and still subsists, having various affiliated societies in other places. The A. degl'i Umidi, one of the oldest of these associations, became afterwards the Florentine Academy. The A. degli Intronati (of the Deaf), degli Umoristi (of the Humourists), and many others with similar quaint appellations, have acquired celebrity in Italy. Of her philological academies, the most illustrious is that della Crusca (of the Sieve), at Florence, which, by the publication of its dictionary, established the Tuscan dialect as the standard of the national language; it is now incorporated with the A. Florentina. In France, the Académie Française was founded in 1635 by cardinal Richelieu. It was an association formed for the purpose of refining the French language and style; and, although in its first period it was chiefly remarkable for the adulation which it bestowed on its vain though able founder, it became, in process of time, by far the most celebrated and influential of all European literary societies. It consisted of 40 members, and a place among them was eagerly sought after, for a long period, as one of the highest honours which could be attained by an author. Like that of Crusca, it published a dictionary of the French language, in 1694. The Royal Academy of Sciences was founded by Louis XIV., in 1666, and published 130 volumes of memoirs, up to the year 1793, when it was abolished by the Convention. The Academies of Painting and Sculpture, and that of Inscriptions and Belles Lettres, were the other two principal academies of Paris. The latter was founded by Colbert in 1663, and remodelled in 1701. At the Revolution all four were abolished: and, in 1795, at the suggestion of Condorcet, the National Institute of France was established in their stead. It consisted of four classes, arising out of the four academies of which it was composed. According to its re-organisation by Napoleon, in 1806, these classes were remodelled, and each of them consisted of a certain number of sections, each furnished with a specified number of acting and corresponding members. The first class, or that of sciences, had sixty-three members, and 100 correspondents; that of languages, forty, and 60 correspondents; that of history and antiquities, forty, and 60 correspondents; that of the arts, twenty-eight, and 36 correspondents. The first, third, and fourth, named each eight foreign associates. In 1816, the Institute was again remodelled by Louis XVIII. The four classes again took the name of academies, and became more independent of each other, their joint property being managed by a commission of eight members, two from each, under the superintendence of the minister of the interior. The first academy (that of sciences) retained the same number of members. The second and third were reduced to thirty-eight and thirty-seven respectively; the fourth, increased to forty. The Academy of Inscriptions and Belles Lettres, and that of Sciences, had added to them a class of free academicians, of the number of ten, with no privilege except that of attendance; the Academy of Arts had the right to choose its own number of free members.

Of similar institutions in Germany, the oldest was the Academia Naturæ Curiosorum, a scientific association, founded in 1652, in Franconia; afterwards taken under imperial protection, when it received the name of the A. Cæsareo Leopoldina. The Royal A. of Sciences, at Berlin, was founded in 1700, by Frederic I. of Prussia: Leibnitz was its first director. The Imperial Academy of Sciences at St. Petersburgh was founded by Catharine I., and endowed by Catharine II. with great munificence, but established on the French model: she separated from it the Academy of Arts.

In England, the name academy has been chiefly confined to associations for promoting the arts. The Royal Academy of Arts was founded in 1768, and consists of forty members: it has separate professors of painting, architecture, anatomy, and perspective; and a council of nine is elected annually. The Academy of Ancient Music was founded by private association, in 1710: the Royal Academy of Music, under the patronage of George III., but dissolved shortly after. Our principal literary and philosophical societies, answering in character to the branches of the French Institute, are, 1. The Royal Society of London, which is confined to objects of a scientific character. It had its origin as early as 1645, but was established by royal charter in 1662. Its acts have been published, under the name of Philosophical Transactions, from 1665 to the present day. 2. Those of the Antiquarian Society, which was established in 1751, are published under the title of Archæologia. 3. The Royal Society of Arts originated in 1718. 4. That of Literature, in 1823. Besides these, there are numerous societies which bear the name of the peculiar branch of science to which their exertions are confined. The Royal Society of Edinburgh obtained a charter in 1783, and another, with more liberal provisions, in 1811. Among the most valuable published transactions of academies and similar societies, besides those already mentioned, are those of Colbert's A. des Inscriptions et Belles Lettres (50 vols. 4to. from 1701 to 1793): those of the Institute, being continuations of the memoirs of the former academies of which it was composed: those of the A. Royale des Sciences and Belles Lettres at Berlin; at first in Latin, then in French (from its remodelling in 1744 by Frederick the Great), now in German. The "Acta" of the Imperial Academy of St. Petersburgh. The "Commentarii" of the A. of Bologna. The Antichita d'Ercolano, published by the Herculanean Academy of Naples.

ACADEMY. In the sense of a place of instruction, is now in this country a term chiefly appropriated to schools for students in the fine arts. The fourth division of the Institute at Paris consists of the Académie

des Beaux Arts. In London, an Academy of Painting seems to have been established in 1712, under the presidency of Sir G. Kneller, but to have shortly after fallen into decay. The present Royal Academy of Arts, founded in 1768, has been already mentioned. In France the old universities were suppressed at the Revolution; but most of them, with some recent ones, have since been restored under the title of *Académies Universitaires.* Their collective body, represented by the re-union of their rectors, inspectors, deans, &c., constitutes the University of France, at the head of which is the Minister of Public Instruction. Colleges in France are equivalent to high schools in this country.

ACADEMY FIGURE. In Painting. A drawing usually made with black and white chalk, on tinted paper, after the living model.

ACALE′PHANS, Acalephæ. (Gr. ακαληφη, *a nettle.*) A class of radiate invertebrate animals, so called on account of the singular property possessed by most of the species therein comprehended, of irritating and inflaming the skin when touched. The class includes the animals called 'medusæ,' 'sea-nettles,' 'jelly-fish, 'Portuguese men-of-war,' &c.; these are divided by Cuvier dichotomously into those which have air-bladders for swimming, or the 'hydrostatic acalephans,' and those which have not, or the 'simple acalephans,' and which swim by means of external cilia, or by the contractions and dilatations of their gelatinous body. All the species are aquatic and marine.

ACA′MPTOSO′MES. (Gr. α, *without*, καμπτω, *I bend*, σωμα, *the body.*) An order of cirripeds including all those in which the body is entirely enveloped in a calcareous compound shell, and so attached that it cannot be unfolded and protruded.

ACANTHA′CEÆ. (*See* Acanthus.) A natural order of monopetalous exogenous plants, in which the genus acanthus is stationed. They have irregular didynamous flowers, and are particularly known by their calyx being imbricated in two broken whorls, and by their seed growing from hooks on the placenta. Many of this species have beautiful flowers, others are mere weeds. They are found wild only in hot or temperate climates.

ACA′NTHIA. (*See* Acanthus.) The name of a genus of hemipterous insects of the tribe *Geocorisæ*, characterised by a long and straight rostrum, sheathed at its base, or through its entire length; labrum very prominent; eyes of large size; and the head presenting, at its junction with the thorax, neither a neck nor a sudden constriction. In some of the species (subgenus *Syrtis*) the anterior pair of legs terminate in a monodactyle chela, or forceps claw, like that of the crustacea, adapted for seizing a living prey.

ACA′NTHOCE′PHALANS, Acanthocephala. (Gr. ακανθος, *a thorn*, and κεφαλη, *a head, spiny-headed.*) An order of intestinal worms, or entozoons, which attach themselves to the mucous coat of the intestines by means of a proboscis surrounded with minute recurved spines.

ACA′NTHOPHIS. (Gr. ακανθος, *spine*, and οφις, *serpent.*) A genus of venomous serpents, allied to the viper, peculiar to Australia, and characterised by a horny spine, simulating a sting, at the end of the tail.

ACA′NTHOPODS, Acanthopoda. (Gr. ακανθος, and πους, *a foot, spine-footed.*) This name is applied to a tribe of clavicorn coleopterous insects, including those species which have spiny legs.

ACA′NTHOPTERY′GIANS, Acanthopterygii. (Gr. ακανθος, and πτερυξ, *a wing or fin, spiny-finned.*) Cuvier's first order of fishes, characterised by the bony spines which form the first rays of their dorsal and anal fins, and generally, also, the first ray of the two ventral fins.

ACA′NTHU′RUS. (Gr. ακανθος, *a spine*, and ουρα, *a tail.*) A genus of spiny-finned fishes, characterised by trenchant and serrate teeth, and by having a strong movable spine, sharp as a lancet, on each side of the tail, by means of which these fishes have the power of inflicting very severe wounds.

ACA′NTHUS. (Gr. ακανθος, *a spine.*) A spiny herbaceous plant with pinnatifid leaves, and large whitish flowers enveloped in spiny bracts, found in various parts of the Levant. Its leaf is said by Vitruvius to have been the model on which the architects of Greece formed the leaves of the Corinthian capital, and that the idea of so applying it was derived from the following circumstance: — The leaves of acanthus grow in a tuft close to the ground, and sprout annually. It happened that a basket covered with a tile was left upon the crown of the root of an acanthus plant, which, when it began to grow in the spring, finding itself unable to arrange its leaves in the usual manner, turned them up round the sides of the basket, till encountering the edges of the tile, they gradually curved back in a kind of volute. Other leaves, besides those of the acanthus, are employed in the decoration of capitals; those, for instance, in the composite order of the arches of Titus and Septimius Severus, at Rome, have, from their strong indentations, more resemblance to parsley than to acanthus leaves, whilst those to the Temple of Vesta, at Rome, have a resemblance to laurel leaves. In Egyptian architecture, the palm leaf frequently occurs.

ACA′RDIA. (Gr. α, *without*, and Lat. cardo, *hinge.*) A term applied to a genus of fossil ostracean bivalves, in which the hinge is wanting, and the flat valve is applied to the convex valve, like a lid to a vessel; the two having been connected only by the adductor muscle.

A′CARI. (Gr. ακαρι, *a mite.*) In Entomology the term is restricted to the tracheary arachnidans which have, either a single-jointed chelicer, or pincer representing an antenna, or a suctorious mouth. All the species are extremely minute, or even microscopic, as the cheese-mite (*Acarus domesticus*), and many of them parasitic; of the latter, the itch-insect (*Sarcoptes scabici*) is a remarkable example. The mites are active insects, and possess great powers of life, resisting for a time the application of boiling water, and living long in alcohol.

ACCE′DAS AD CU′RIAM. In Law, the title of a writ which removes a plaint from an inferior court, generally the county court, as the issuing of which is a preliminary to trying a question of right upon a distress of goods by the proceeding called Replevin (which see).

ACCELERA′TION. (Lat. acceleratio, *hastening.*) In Mechanics, an increase in the velocity of bodies in motion. Acceleration is uniform or variable, according as the force by which the motion is produced acts regularly or irregularly.

The most familiar instances of uniformly accelerated motion, are those which are occasioned by the earth's attraction, and are exhibited in the falling of heavy bodies, or their descent along inclined planes. In both these instances, the observer cannot fail to perceive that the velocity becomes greater as the body falls from a greater height, or continues a longer time in motion. In order to explain the theory of acceleration from the action of gravity, it is necessary to recollect that, in virtue of the inertia of matter, a body always perseveres in its state of rest, or of uniform motion in a straight line, till, by some external influence, it is made to change its state. This is Newton's first law of motion, which is admitted as a principle or axiom in mechanics, and from which it follows, that as a body cannot accelerate its own motion, any change in the rate of velocity of a moving body must arise from the action of an extraneous force. Now, suppose a body to be carried to a considerable height above the earth, and abandoned to the action of gravity; and let us examine the circumstances which take place. In this supposition, gravity may be regarded as a force acting uniformly; for, though its intensity diminishes as the distance from the centre of the earth increases, yet any height to which we can reach is so small, compared with the radius of the earth, that the variation in the intensity of gravity depending on it may be disregarded. Let the time which the body takes to fall to the earth be divided into equal and small intervals. During the first interval an impulse is given to the body, and a certain motion is communicated. If gravity now ceased to act, the body would continue to descend uniformly with the velocity it had acquired; but the impulse is renewed with exactly equal vigour during the second interval, and, consequently, the velocity of the body is exactly doubled. The same thing is repeated in the third interval, and, consequently, the velocity of the body is then tripled. In the fourth interval it is quadrupled, and so on; the body continually receiving, during equal and successive intervals of time, equal increments of velocity from the action of the accelerating force, and preserving its acquired velocity in consequence of its inertia. Hence we infer the first great law of uniformly accelerated motion, namely, the velocity at any given moment is proportional to the number of impulses that have been received, or to the number of intervals that have elapsed since the commencement of the motion; in other words, *the velocity is proportional to the time.*

Let us now consider the spaces passed over by the falling body. Suppose the space through which the body falls during the first interval, or second of time, to be one pole. As the velocity is supposed, at the commencement of the motion, to be nothing, and to increase uniformly during the interval, it is evident that the space passed over will be the same as if the body had continued during the interval to move uniformly with the mean velocity, or the velocity it had at the middle of the interval. But the velocity has been shown to be proportional to the time. Hence, at the end of the first second the velocity is the double of what it was at the middle of the second; and, therefore, if gravity ceased to act, the body, during the second interval or second, would descend through two poles. In consequence, however, of the renewed action of gravity, the body receives a fresh impulse during the second interval equal to that which it received during the first, and is, consequently, carried through a space equal to one pole, in addition to that

through which it is carried by its previously acquired velocity. Hence, during the second interval the body falls through three poles. At the end of this time the velocity is the double of what it was at the end of the first interval, and, consequently, during the next second would carry the body through four poles. Add, again, the effect of the renewed impulse, and the space passed over by the body in the third second is five poles. In the same manner, we find the space passed over in the fourth second to be seven poles; in the fifth, nine poles, and so on; the spaces described in the successive seconds being proportional to the series of odd numbers, 1, 3, 5, 7, 9, 11, &c. Adding, therefore, these numbers successively, we shall have the spaces passed over, since the commencement of the motion, represented by the series of square numbers, 1, 4, 9, 16, 25, 36, &c. Whence the second great law of uniform acceleration, namely, *the spaces described are proportional to the squares of the times.*

Galileo was the first who discovered the laws of acceleration of falling bodies. He supposed the acceleration to take place by equal degrees, or to be uniform; and experiment has confirmed his hypothesis. (*See* GRAVITY, GRAVITATION.)

What has now been said, with respect to motion uniformly accelerated, applies equally (*mutatis mutandis*) to motion uniformly retarded. It will also be perceived that the effect of the resistance of the air has been neglected.

ACCELERA'TION OF THE FIXED STARS denotes the apparent greater diurnal motion of the fixed stars than of the sun; in consequence of which they daily come to the meridian of any place at an earlier hour of the solar day than they did on the day preceding. Thus, a star which to-day passes the meridian at six o'clock, mean time, will pass the meridian to-morrow three minutes and fifty-six seconds before six o'clock. The reason of this is, that the sun, which appears to make a complete revolution of the heavens, from west to east, in the course of a year, advances daily nearly a degree eastward among the stars; and the apparent diurnal motion, being from east to west, the sun's passage over the meridian is retarded daily about three minutes and fifty-six seconds of time, in respect of the stars. But our clocks are regulated by the sun; consequently, in reference to them, the daily transit of the stars over the meridian is accelerated. (*See* SIDEREAL TIME.)

ACCELERA'TION OF THE MOON. An increase of the mean angular velocity of the moon about the earth; in consequence of which, the time of her mean periodic revolution is somewhat shorter than it was many centuries ago. This acceleration is exceedingly small, amounting only to about ten or eleven seconds of a degree in a century. It was discovered by Dr. Halley, from a comparison of very ancient with modern observations, and was confirmed by an examination of the observations of the Arabians in the 9th and 10th centuries. Its physical cause long occasioned great perplexity to mathematicians, and was at length detected by the genius of Laplace. It depends on a very slow secular diminution of the eccentricity of the earth's orbit. One of the greatest discoveries in physical astronomy is, that all variations in the elements of the planetary system are periodic. Some centuries after the present time, the eccentricity of the earth's orbit will arrive at its minimum value, and then begin to increase. When this period arrives, the mean motion of the moon, which for many centuries has been accelerated, will begin to be retarded. (*See* PLANETARY SYSTEM, and PERTURBATION.)

ACCELERA'TION OF THE PLANETS. The motion of a planet in its orbit is variable, being quicker or slower, according as the planet is at a less or a greater distance from the sun. Hence, in moving from the apogee to the perigee of the orbit, the motion of a planet is accelerated; and, on the contrary, in moving from the perigee to the apogee, the motion is retarded.

A'CCENT. (Lat. ad, *to*, and cano, *I sing.*) In ordinary language, the greater or less stress laid in pronouncing on each syllable of a word is termed the accent of that syllable. But the accent of a Greek syllable is a species of tone, respecting which very contradictory notions prevail among modern commentators, and of which it is indeed difficult to form any accurate conception. The history of the employment of accentual marks in writing the Greek language, is extremely obscure. They are found in manuscripts of considerable antiquity. In our pronunciation of Greek, they are wholly neglected, quantity being our only guide in the stress which we lay on the syllable of each word. But the modern Greeks pronounce their language, in general, laying the stress on the accented syllables, and neglecting the quantity. The mark of the acute accent is ʹ; of the grave ˋ; of the circumflex, which is a compound of the other two, ^, or ~. But every syllable which has no accentual mark is said to have the grave accent; the grave being only marked on final syllables of words which have no acute accent on any syllable. These three accentual marks are also employed in the French language; but in it they are only employed, for convenience, to mark a difference in the pronunciation, not in the accent; the modifications of the vowel sounds not being all of them expressed by distinct letters.

ACCENT. In Music, a certain stress or forced expression laid on certain parts of a bar or measure.

ACCE'NTOR. A genus of seed and insect-eating passerine birds, of which the hedge-chanter, or as it is commonly called, the hedge-sparrow (*Accentor modularis*), is a well known example.

ACCE'PTANCE. *See* BILL OF EXCHANGE.

ACCE'PTOR. (Law.) *See* BILL OF EXCHANGE.

A'CCESSARY. (Lat. accedo, *I approach.*) In Law, an accessary to an offence is one who is not the chief actor, or present at its performance, but is concerned therein, either before or after the fact. An accessary before the fact, is one "who, being absent at the time of the crime committed, doth yet procure, counsel, or command another to commit a crime." An accessary after the fact, is one who, knowing that a felony has been committed by another, receives, relieves, comforts, or assists the felon. (*See* LAW, CRIMINAL.)

ACCESSARY, or ACCESSORY. (Fr. *accessoire*). In Painting, and the fine arts, is a term which extends to every thing introduced into a work that is not absolutely necessary. In an historical picture, for instance, the figures which are in action are the principal objects; by them the story is told, all the rest are accessories. Especial care is to be taken, that they be so selected and disposed, as not to interfere with the principal group; hence the ancient painters and sculptors were very shy of using them, lest the eye should be drawn away from the principal group, and its interest be thus lessened or destroyed.

ACCE'SSION. In international law, the act by which one power enters into engagements originally contracted between other powers. The accession of a sovereign is the period at which he assumes the sovereignty, and in hereditary monarchies takes place immediately on the decease of his predecessor.

ACCIA'CCATU'RA. (It. acciaccare, *to squeeze.*) In Music, a grace note, one semitone below that to which it is prefixed or, as it were, squeezed in.

A'CCIDENS, *per accidens*. A term used by the older philosophers to denote an effect not following from the nature or essence of the thing, but from some accidental quality. It is opposed to *per se.* Thus, fire burns *per se;* heated iron burns *per accidens.*

A'CCIDENT. In Logic, one of the predicables: in its strictest logical sense, it is that which may be absent from or present in the subject, the essence of the species to which the subject belongs remaining the same. Thus, it may be predicated of a man, that he is "walking," or that he is "a native of Paris:" the first of which examples expresses what is termed a separable accident; the latter, an inseparable; i. e. the individual may cease to walk, but cannot cease to be a native of Paris: but neither of these alter the species, man, to which the individual belongs. But it is to be observed, with regard to the accident, as well as the other predicables, that they exist only relatively to each other; so that the same quality may be accidental when predicated of the species, which is a property when predicated of the individual. Thus, "malleability" is an accident of the subject "metal," because many metals are not malleable. But it is one of the properties of gold, iron, &c., as distinguishing these from the non-malleable metal. (*See* PREDICABLE.)

ACCIDE'NTAL COLOURS. Colours depending on some affection of the eye, and not belonging to light itself, or any quality of the luminous object. If we look for a short time steadily with one eye upon any bright-coloured spot, as a wafer on a sheet of paper, and immediately after turn the same eye to another part of the paper, a similar spot will be seen, but of a different colour. If the wafer be red, the imaginary spot will be green; if black, it will be changed into white; the colour thus appearing being always what is termed the complementary colour of that on which the eye was fixed.

ACCIDE'NTAL POINT. Perspective. The point in which a straight line drawn from the eye, parallel to another straight line, cuts the perspective plane. It is the point in which the representations of all straight lines parallel to the original straight line concur when produced. It is called the accidental point, to distinguish it from the principal point, or point of view.

ACCIDE'NTALS. (Lat. accidentalis, *happening by chance*). In Painting, are those fortuitous or chance effects, occurring from luminous rays falling on certain objects, by which they are brought into stronger light than they otherwise would be, and their shadows are consequently of greater intensity. This sort of effect is to be seen in almost every picture by Rembrandt, who used them to a very great extent. There are some fine instances of accidentals in Raphael's Transfiguration, and particularly in the celebrated picture, the *Notte* of Coreggio, in which the light emanates from the infant Christ. With these effects may be classed such acci-

dental lights as those from a forge or a candle, or some such object, of which the use is extremely important to the painter of still life.

ACCIDENTALS. In Music, are those flats and sharps which are prefixed to the notes in a movement, and which would not be considered so by the flats and sharps in the signature.

ACCI′PITRES. (Lat. accipiter, *a hawk*) The name of the Linnæan order, including the birds of prey.

ACCLI′MATISE. (Lat. ad, *to*, and clima, *a climate*.) The art of cultivating exotic plants so as to inure them to a climate different to that which is natural to them. An acclimatised plant or animal differs from a naturalised one, in always requiring the assistance of art for its continuance in the adopted climate; the naturalised plant or animal continuing its kind without any care from man. The capacities of different plants and animals for being acclimatised, or naturalised, vary, but not to the extent that at first sight may be imagined; what passes under these terms being frequently nothing more than the fortunate discovery that some plant or animal, which had hitherto been found in a warm climate, would thrive equally well in a cold one.

ACCOLA′DE. (Lat. ad, *to*, and collum, *the neck*.) The slight blow given to the neck or shoulder, on dubbing a knight.

ACCO′MPANIMENT. In Music. The instrumental part of a composition which moves with the voice, to which it is to be kept subordinate. Also, the parts which in a concerted piece move with a particular instrument, whose powers it is the object of the composition to exhibit.

ACCOMPANIMENT. In Painting. Any object accessary to the principal subject, and serving to its ornament or illustration.

ACCO′MPLICE. In Law, is defined to be one of many concerned in a felony. (*See* ACCESSARY, APPROVER.)

ACCO′RD. (*See* CONCORD.)

ACCOU′NTANT-GENERAL. The principal or responsible accountant in the offices of Excise and Customs, India House, Bank of England, &c. The accountant-general of Chancery is an officer appointed by act of parliament to receive all the money lodged in court. He keeps his account with the Bank of England, which is responsible for all the sums lodged there by him.

ACCRE′SCIME′NTO. (It. accrescere, *to increase*.) In Music, the increase, by one half of its original duration, which a note gains by having a dot appended to the right of it.

ACCU′MBENT. (Lat. accumbere, *to lie down*.) Is a term applied, in botany, to cases where one part of an organ is applied to another by its edge; it is chiefly used in contradistinction to *incumbent*, where one part is applied to another by its back or face. These terms are principally employed among brassicaceous (cruciferous) plants.

ACCU′SATIVE CASE. That inflexion of the noun which expresses the passing over of an action from one substance to another: it consequently follows verbs active in all languages. In English it survives only in pronouns; and is used after all prepositions without distinction. (*See* GRAMMAR.)

ACE′PHALANS, Acephala. (Gr. ακεφαλος, *headless*.) A term applied to a class of molluscous animals, comprehending those which are without a head. The class is subdivided, according to the modifications of the respiratory organs, into the 'Lamelli-branchiate,' 'Pallio-branchiate,' and 'Hetero-branchiate,' or tunicate orders. (*See* those words.) The oyster, lamp-cockle, and squirter, or ascidia, are their several representatives. In the system of Cuvier it includes only the lamelli-branchiate and hetero-branchiate orders, or the acephala testacea, and the acephala nuda.

ACE′PHALOPHO′RES, Acephalophora. (Gr. ακεφαλος, and φερω, *I bear*.) The name given by Blainville to a class of molluscous animals corresponding to the acephala and brachiopoda of Cuvier.

ACE′PHALOUS. A botanical term, occasionally employed to designate ovaries, the style of which springs from their base, instead of their apex, as in lamiaceæ.

ACEPHALOUS. In Anatomy, is applied to those malformed fœtuses which are without a head.

A′CER. (Celt. ac, *a point*; Lat. acer, *sharp*. Pikes were made from the wood.) A genus of hardy trees, comprehending the common maple, the sycamore, and various kinds of American maples. Their wood is not of much value, being usually light and perishable; but the knotted parts of Acer campestre furnish the pretty bird's-eye maple of cabinet makers. The sap of Acer saccharinum is so sweet that sugar, of good quality, is prepared from it in North America. Acer platanoides, the Norway maple, is one of the best trees for planting in places exposed to the sea air.

ACERA′CEÆ (*see* ACER), or ACERINEÆ. A small natural order of polypetalous exogenous plants, comprehending the genus acer, and three others. It consists of trees, or at least of woody plants, inhabiting the temperate parts of the world; their most essential character consists in their samaroid dicarpellary fruit, connected with a broken whorled calyx, and unsymmetrical flowers without scales at the base of the petals. The uses of the order are the same as those of acer.

A′CERANS, Acera. (Gr. ἀ, *without*, and κερας, *a horn*.) A name applied to a family of apterous insects, characterised by the absence of antennæ: and to a family of gastropodous mollusks, including those species which have no tentacles.

A′CERIC ACID. (Lat. acer, *the maple*.) An acid obtained from the sap of that tree.

ACERO′SE. This word literally means chaffy (Lat. panis acerosus, *chaffy* or *brown bread*). Botanists apply the term to leaves of a narrow, stiff, and pungent nature, like those of fir trees.

ACETA′BULUM. (Lat. *a little cup*, or *dish*.) A term applied to the suckers on the arms of the cuttle-fish, and other dibranchiate cephalopods, which have been, hence, recently termed *acetabulifera*. These suckers were called by Aristotle *kotuloi*, which Taylor has erroneously rendered 'joints,' in the English translation of the History of Animals. In anatomy, *acetabulum* signifies the cavity of the hip-joint. In entomology it is the socket on the trunk in which the leg is planted.

ACETA′RIOUS PLANTS. (Lat. acetaria, *a salad*.) Plants used in salading; such as lettuce, mustard and cress, endive, &c.

ACE′TATES. Salts containing acetic acid. (*See* VINEGAR.)

ACE′TIC ACID. The pure acid contained in vinegar. It is a pungent acrid liquid; its odour, when diluted, is agreeable and refreshing; when perfumed, it is known under the name of *aromatic vinegar*.

ACHÆ′AN LEAGUE. A confederacy which existed from very early times among the twelve states of the province of Achaia, in the north of the Peloponnesus. It was broken up after the death of Alexander the Great, but was set on foot again by some of the original cities, B. C. 280, the epoch of its rise into great historical importance; for from this time it gained strength, and finally spread over the whole Peloponnesus, though not without much opposition, principally on the part of Lacedæmon. It was finally dissolved by the Romans, on the event of the capture of Corinth by Mummius, B. C. 147. The two most celebrated leaders of this league were, Aratus, the principal instrument of its early aggrandisement; and Philopæmen, the contemporary and rival, in military reputation, of Scipio and Hannibal. (*See* Polybius, i. ii. Pausanias, l. vii. Schlosser's Universal History. Clinton's Fasti Hellenici.)

ACHÆ′NIUM, or ACHENIUM. (Gr. ἀ, *without*, and χαινω, *I gape*.) A small bony fruit, containing a single seed, which does not adhere to the shell or pericarp, nor open when ripe.

ACHA′TMA. A genus of terrestrial gastropods, known by the trivial name of agate-snails: characterised by an oval oblong ventricose shell, striated longitudinally; with the aperture ovate and never thickened or reflected, and a smooth, straight columella, truncated at the base. All the species are oviparous, and one, the *Achatma zebra*, produces eggs with a hard, white, calcareous shell, and as large as those of the sparrow.

A′CHERON. (Gr. αχος, *grief*.) The river of sorrow which flowed round the infernal realms of Hades, according to the mythology of the ancients. There was a river of Thesprotia, in Epirus, of the same name, and also one in Italy, near which Alexander, king of the Molossi, was slain; both of which, from the unwholesome and foul nature of their waters, were supposed to communicate with the infernal stream.

ACHIE′VEMENT. (Fr. achever, *to accomplish*.) In Heraldry, denotes generally a shield of armorial bearings; but is more particularly applied to the funeral shield, commonly called hatchment, affixed to the dwelling-house of a recently-deceased person. The achievement is various, according not only to the rank of the deceased party, but to his situation as single, married, or widower.

ACHLAMY′DEOUS. (Gr. ἀ, *without*, and chlamys, *a tunic*.) Plants which have neither calyx nor corolla, and whose flowers are consequently destitute of a covering, or naked.

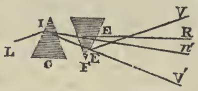
ACHROMA′TIC. (Gr. ἀ, *without*, χρωμα, *colour*.) Free from colour.

ACHRO′MATISM. The destruction of the primary colours which accompany the image of an object seen through a prism or lens. Light is not homogeneous, but compounded of rays unequally refrangible, and differing from one another in other physical properties. In passing into a refracting medium, some of the rays are more refracted, or bent out of their course, than others; whence the image of an object, seen through a lens, is rendered confused and indistinct, and appears encircled by a coloured ring. This circumstance presented a formidable obstacle to the use of the telescope; and, accordingly, soon after the invention of that admirable instrument, the utmost efforts

of mathematicians and artists were exerted to remove the imperfection. The compound nature of light, and, consequently, the theory of unequal refrangibility, were, however, not known till the time of Newton; and after the true source of the difficulty had been made known, it continued for a long time to be believed that achromatism was impossible, or that light could not be deflected without being decomposed. Newton himself was conducted to this conclusion by imperfect experiments. Subsequent discoveries have proved that the conclusion was erroneous, and that the rays of light may be bent without being separated; but, after all, the progress that has been made in the arts, as well as in the theory of colours and light, the subject of achromatism continues to be one of the most delicate and embarrassing, both in regard to theory and practice.

The principles on which achromatism is effected, may be briefly explained, as follows. On observing the spectra formed by prisms of different substances, it is soon perceived that the different colours, though always ranged in the same order, do not occupy the same relative lengths. A prism of flint glass, for example, exhibits proportionally less red, and more violet, than a prism of crown glass; and, in some other substances, the difference is still more remarkable. Hence it follows, that the primary coloured rays, in passing through different substances, do not undergo the same relative refractions; that is to say, the angle formed by two rays, the red and the violet, for example, is greater when the light is refracted by some substances than when it is refracted by others, though in all substances the violet is more refracted than the blue, the blue more than the green, and so on. The angle formed between the extreme rays of the spectrum measures the *dispersion* of the rays; and it is found by experiment that the dispersive power of common flint glass is to that of crown glass in the ratio of about 3 to 2; so that if a prism of flint glass give a spectrum three inches long, a similar prism of crown glass will give a spectrum of only two inches.

Now, suppose a prism of crown glass, C, the faces of which make an angle of 25°, and a prism of flint glass, F, of 20° 21′ 43″, to be placed behind it, and that a ray of direct or white light, L I, falling on the first prism at I, emerges from the second between the points E and E′. It is known by experience, that when the angles of the two prisms



are as above stated, the violet ray E V, on emerging from the second prism, is parallel to the incident ray L I; and that the red ray E′ R must fall below E V, because the red ray only emerges parallel to the incident ray when the angle of the prism of flint glass is 20° 56′ 28″. But if the prism of flint glass were removed, or, which would be the same thing, if its sides became parallel, and, consequently, its angle = 0, the red ray E′ R would fall above the violet ray E V, the violet being more refrangible than the red. While the angle F, therefore, increases from 0° to 20° 56′ 28″, the emerging rays E′ R and E V change their relative positions; whence it follows, that at some intermediate angle of the prism F they will be parallel, and this is the angle of achromatism. It is found by experience to be 11° 58′ 3″; varying, however, between narrow limits according to the peculiar constitution of the two refracting substances; and, therefore, in determining the ratio of the angles of the two prisms, recourse must generally be had to particular experiments on the individual substances of which the prisms are composed.

The achromatism of lenses depends on the same principles, and is determined in the same manner, as that of prisms; but in the case of lenses, the compensation is attended with great practical difficulties, on account of its being necessary to have regard to the spherical aberration.

If the ratios of the dispersion of the different spectral colours were all equal, the achromatism would be perfect when the extreme rays, or, indeed, any two rays, emerge parallel. This, however, is not generally the case; these ratios are in general variable, and, therefore, the angle which renders the red and violet rays parallel is not that which is required for the intermediate colours. It is possible, however, to remedy this defect, by combining a greater number of prisms or lenses. Theoretically speaking, indeed, the number of rays united or rendered parallel is the same as the number of prisms. The achromatic object-glasses of telescopes formerly made in this country, were generally triple; that is to say, consisted of three lenses, namely, a concave lens of flint glass placed between two lenses of crown glass: but almost all the large object-glasses lately constructed consist of only two lenses; the achromatism produced by this combination, though not rigorously exact, being sufficient for optical purposes.

The possibility of refracting light without producing colour was discovered and experimentally proved by Mr. Hall, a country gentleman of Worcestershire, under whose directions an achromatic telescope was made by a London artist in 1733. But, from whatever cause, no notice was taken of Hall's discovery; indeed, it appears to have been entirely forgotten, and contributed nothing whatever to advance subsequent researches. The merit of the discovery of achromatic compensation belongs to John Dollond, who arrived at it through a long course of skilful and systematic experiments undertaken for the express purpose. Its possibility had, indeed, been previously asserted by the celebrated Euler, who, reasoning from the construction of the eye, which, indeed, is a perfect achromatic instrument, proposed various hypotheses for destroying the coloured images. After Dollond's discovery, the subject was examined theoretically by Euler, Clairaut, and D'Alembert, but their profound mathematical investigations led to no practical improvement. The object-glasses made by Peter Dollond (a son of the inventor) were long celebrated throughout Europe as the best that were manufactured. Of late years, however, the science of light has been vastly extended; and the discoveries of Fraunhofer, in particular, have opened up an entirely new view of the composition of the spectrum. The largest and best achromatic glasses have recently been made in Bavaria and Switzerland. (*See* CHROMATICS, REFRACTION.)

ACI′CULAR. (Lat. acicula, *a needle*.) Any thing that is slender, sharp-pointed, and rather stiff; as many kinds of prickles on the leaves of plants, &c.

A′CID. In common language, any *sour* substance; in chemistry the term is less restricted, and often applied to all substances which saturate and neutralise the alcalis and other salifiable bases, without other obvious acid properties.

ACIDIFI′ABLE. Convertible into an acid.

ACI′DULOUS. *Dim.* of acid. Subacid; a term frequently applied to mineral waters containing carbonic acid.

ACI′NACIFORM. (Lat. acinaces, *a scimitar*, and forma, *shape*.) A name applied to certain succulent leaves and fruits, which resemble the blade of a curved sword or Turkish scimitar.

A′CINUS. (Gr. *ακινος*, *the stone of a grape*.) The separate carpels of a succulent fruit consisting of many carpels; as the raspberry. This term is also applied in anatomy to a cluster of the ultimate secerning follicles of certain conglomerate glands; as the liver.

ACIPE′NSER. (Lat. acipenser, *a sturgeon*.) The name of a Linnæan genus of the amphibia nantes, characterised by solitary, lateral, linear gill-openings; the mouth, situated beneath the head, retractile and edentulous; feelers under the snout, in front of the mouth. The sturgeon (acipenser sturio), and most of the other amphibia nantes of Linnæus, form the order chrondropterygii, or cartilaginous fishes of Cuvier. The genus acipenser is separated by Agassiz from the other cartilaginous fishes. It forms a link between the osseous and cartilaginous fishes, having its gills protected by an operculum, and only a single issue, or gill-opening, on each side for the respiratory currents; but at the same time having no rays to the branchiostegal membrane, and having the whole of its true internal skeleton in a cartilaginous state. By Cuvier, therefore, the genus acipenser is placed in the cartilaginous division of fishes, but separated from the rays, sharks, and lampreys, which have five or more gill-openings on each side, to form, along with the genera spatularia and chimæra, the order eleuthero-branchiata, or those which have the branchiæ free at their outer circumference. In the system of Agassiz the sturgeons are joined with the sauroid fishes, siluri, polypterus, and some other genera, to form the order Ganoides. (*See* that word.) And it is worthy of observation, that the polypterus (a ganoid fish of the Nile) has a spiral valve in the intestine like that of the sturgeon.

There are several distinct species of acipenser in the Danube, and other great rivers of Europe; but that which is occasionally caught on our east coast, and is commonly brought to the London market, is the Acipenser Sturio of Linnæus, or the common sturgeon.

The largest specimen ever caught in this country is, probably, that which is recorded by Pennant as having been taken in the Esk, and which weighed four hundred and sixty pounds.

In England the sturgeon is considered a royal fish, and its use is exclusively as an article of luxury for the table; its flesh, like that of most cartilaginous fishes, is firmer than is usual among osseous fishes, and having little peculiar flavour of its own, affords ample scope for the skill of the cook in imparting to it an extrinsic zest.

In the northern parts of Europe this fish is much more numerous than in the British rivers, and extensive fisheries are established for its capture. The best isinglass is manufactured from the sound, or air-bladder; and caviare is prepared from the roe of the female.

ACKNOW′LEDGEMENT-MONEY, in Law, paid according to the custom of some manors by copyhold tenants, on the death of a lord.

A′CME. (Gr. *ἀκμη*, *a point*.) In Rhetoric, the extreme

height, or farthest point of pathos, or sentiment, to which the mind is judiciously conducted by a series of impressions gradually rising in intensity. (*See* CLIMAX.)

ACO'LOGY, or AKOLOGY. (Gr. ἀκος, *a remedy*, and λογος, *a discourse*.) The doctrine of remedies, or of the materia medica.

A'COLYTE. (Gr. ακολουθος, *disciple*.) The second of the inferior orders of clergy in the primitive church, according to the Roman Catholic authorities. The Council of Trent declares the inferior orders to be five—subdeacons, acolytes, exorcists, readers, and doorkeepers; considering them all to be of apostolical institution. By the Protestants they are supposed to be merely occasional or local officers. The office of the acolytes, according to the Roman Catholic Catechismus ad Parochos, is to follow and serve the superior orders, the subdeacons and deacons, in the ministry of the altar. Besides this, they carry lights when the sacrifice of the mass is celebrated, whence they are called also ceroferarii (waxbearers).

ACONI'TA, ACONITINA. A poisonous vegetable principle or alkaloid extracted from the aconite.

A'CONITE. (Acone, a place in the Crimea famous for its poisonous herbs.) A genus of exogenous plants belonging to the natural order ranunculaceæ, with showy purple or yellow helmet-shaped flowers, growing in panicles, deeply cut leaves, and perennial roots of a highly poisonous nature. Those of Aconitum lycoctonum are used for the destruction of wolves, and of A. napellus for certain medicinal purposes; they are exceedingly acrid, and act as violent drastic purgatives. The bish root, with which the natives of Nepal poisoned their wells, during the advance of the British army into their territory, during the last war, was furnished by Aconitum ferox. The name aconite has also been given to another plant related to the original genus, namely, eranthis hyemalis, or winter aconite.

ACO'NTIA. (Gr. ἀκων, *a dart*.) A genus of non-venomous ophidian reptiles, allied to the snakes proper (anguis), but destitute of the bony rudiments of the scapular and pelvic arches. They are known by the trivial name of "Dart-snakes;" are numerous in species, and distributed over the warmer and more arid parts of the old world. They were the subjects of fabulous accounts by the ancient naturalists and poets, who attributed to them the power of projecting themselves with so much force and velocity as to transfix the object aimed at, like a hurled javelin, or arrow shot from a bow. This is as untrue as the assertion that they are venomous. The Dart-snakes are amongst the most harmless of their order; their food consists of small worms, insects, and larvæ.

ACORA'CEÆ, or ACOROIDEÆ. The natural order of plants which includes the genus acorus. It is distinguished from araceæ only by having its carpels separate, and its leaves in the bud state arranged in an equitant manner.

A'CORN. (Accorn, Sax. of aac, *an oak*, and cern, *grain*.) The well-known fruit of the oak, and therefore not a term of art, though belonging to architecture from its use as an ornament. In the early ages acorns constituted a principal part of the food of man. (Ovid. Metamorph. i. 106.; Virgil, Georg. i. 8. &c.) At present they are occasionally used in different parts of the Continent during scarcities; but in England they are never used, except for the feeding of pigs, poultry, &c.

A'CORUS. (Gr. ἀκορος.) A plant with sword-shaped leaves and aromatic stems, found abundantly in the meadows of some parts of England. It bears, but very rarely, its flowers in a little greenish yellow spadix, which appears at a short distance below the end of a leaf-like scape. The leaves, when crushed, exhale a pleasant odour, and are still used for strewing the floors of churches upon the occasion of certain ancient ceremonies. Its stem, or rhizoma, is like that of an iris, and is the calamus aromaticus of the druggists.

A'COTYLE'DONS. (Gr. ἀ, *without*, and κοτυληδων, literally, a hollow or concave part, but applied by botanists to the seed-lobe.) Plants whose seeds have no distinct cotyledons. The term is usually applied to what are more commonly named cryptogamic plants, such as ferns, mosses, lichens, &c., in which there are no seeds, properly so called, but which are propagated by undivided spherical bodies called spores. The word acotyledon is occasionally used for such plants as cuscuta, cactus, &c., whose seeds, although really of the same nature as those in which cotyledons are usually present, have no obvious division; this mode of applying the term is, however, seldom employed.

ACOU'STICS. (Gr. ἀκουω, *I hear*.) The science of hearing, or of sound. (*See* SOUND.)

ACQUI'TTAL. In Law. (Lat. acquietare, *to render tranquil*.) Freedom from services to a superior lord. Also, deliverance from a criminal charge by the verdict of not guilty. This verdict may always be pleaded in answer to a second charge on the same offence: the plea is termed "autrefois acquit"

ACQUI'TTANCE. In Law, the discharge in writing of a sum of money due. An acquittance not under seal is admissible only in evidence, and is not pleadable. An acquittance in full of all demands, is an answer to all debts, except such as are on specialty, which can only be discharged by an instrument of equal force.

A'CRE. A measure of land, that formerly varied in different parts of the United Kingdom. The magnitude of the imperial or statute acre may be referred to that of the square yard, by recollecting that a square, whose side is 22 yards long, is the *tenth* part of an acre; whence the latter contains $22 \times 22 \times 10$, or 4,840 square yards. The *chain* with which land is measured is 22 yards long, so that ten square chains are one acre. The acre is divided into 4 roods, and each rood into 40 perches; so that each perch contains $30\frac{1}{4}$ square yards.

Acre.		*Rood.*		*Perch.*		*Square yards.*		*Side of equivalent squares in yards.*
1	=	4	=	160	=	4840	=	69·5701
		1	=	40	=	1210	=	34·7851
				1	=	$30\frac{1}{4}$	=	5·5

121 Irish acres are equivalent to 196 English acres.
48 Scotch acres are equal to 61 English acres.
The French are is a square, whose side is 10 metres: and 1000 English acres are equivalent to 40·466 ares.

ACRI'DIANS, ACRIDIA. (Gr. ἀκρις, *a locust*.) A family of orthopterous insects, having the genus acridium for the type.

A'CRITES, ACRITA. (Gr. ἀκριτος, *indiscernible*.) The lowest division of the animal kingdom, in which there is no distinct discernible nervous system; and in which the alimentary canal is not separated from the parietes of the body, or contained in a distinct abdominal cavity. It is composed of the classes spongiæ, polypi, polygastrica, sterelmintha, acalepha. (*See* those words.)

ACRODA'CTYLUM. (Gr. ἀκρος, *highest* or *extreme*, and δακτυλος, *a digit*.) In Zoology, the upper surface of each digit.

A'CRODUS. (Gr. ἀκρος, *extreme*, οδους, *tooth*.) The name of a genus of sharks, characterised by the presence of large polygonal obtuse enamelled teeth; aggregated at the extremity of the jaws. The fishes of this genus are found exclusively in the fossil state.

A'CROGENS. (Gr. ἀκρος, and γιγνω, *I grow*.) Plants, otherwise called cryptogamous and acotyledonous. They correspond to ferns, mosses, lichens, &c.; have no sexes; are multiplied by spores instead of seeds; and are remarkable for increasing chiefly in length, by additions to their end, and not in diameter, by the addition of fresh matter to their outside, as in exogens, or to their inside, as in endogens.

ACRO'LITHOS. (Gr. ἀκρος, and λιθος, *stone*.) In Sculpture, a statue whose extremities are of stone, the body being made of wood. According to Vitruvius, there was a temple at Halicarnassus dedicated to Mars, and built by Mausolus, king of Caria, wherein was an acrolithan statue of the god. And from Trebellius Pollio we learn that Calpurnia set up an acrolithan statue of Venus, which was gilt.

ACRO'NYCAL, or ACHRONYCHAL. (Gr. ἀκρος, and νυξ, *night*.) A star or planet is said to be acronycal when it is opposite to the sun, or passes the meridian at midnight. It rises acronycally, when it rises as the sun sets; and sets acronycally, when it sets as the sun rises. The Greek poets designated these different positions of a star, at its rising or setting, with respect to the sun, by the terms *acronycal*, *cosmical*, and *heliacal*; and thereby indicated, in a rude way, the position of the sun in the ecliptic, or the season of the year.

ACROPO'DIUM. (Gr. ἀκρος, and πους, *foot*.) In Zoology, the upper surface of the whole foot.

ACRO'POLIS. (Gr. ἀκρος, and πολις, *city*.) The upper town or citadel of a Grecian city. It was usually the site of the original settlement, and was chosen by the colonists for its natural strength. The most celebrated were those of Athens, Corinth, and Ithome; the two latter of which were termed the horns of the Peloponnesus, as if their possession was enough to insure the submission of the whole peninsula.

A'CROSPIRE. (Gr. ἀκρος, and σπειρα, *a curved line*.) When seeds begin to grow, the part of the germ which afterwards produces the stem shoots forth in the form of a delicate curved fibre, and, gradually bursting the outer covering, makes its appearance at the end of the seed. Maltsters, especially, call this the acrospire of barley.

ACRO'STIC, or ACROSTICH. (Gr. ἀκρος, and στιχος, *line*, or *rank*.) A composition in verse or prose, in which the first or last letter of every line, or of every word, read collectively, form a name or a sentence. Great labour and ingenuity have been exercised in inventing varieties of this and similar curious trifles. Such, for example, is the pentacrostic, in which the initial letter of each verse is repeated five times in every verse, so as to form five repetitions of the same acrostic, as it were, in different columns.

ACROTA'RSIUM. (Gr. ἀκρος, and ταρσος, *tarsus*.)

In Zoology, the upper surface of the tarsus. (*See* that word.)

ACROTE'RIA. (Gr. ἀκρωτηριον, *the extremity of any thing.*) In Architecture, the pedestals, often without base or cornice, which are placed on the centre and sides of pediments, and which are so placed for the reception of figures. Vitruvius gives the rules for their dimensions. The same word is applicable to the ridge of a building. Some have used the word acroterion to signify the statues on the pedestals, but it is strictly the pedestals themselves only to which it is applicable. The word acroteria is also used to denote the small pieces of wall in balustrades between the pedestal and the balusters.

ACRY'DIUM. (Gr. ἀκρις, *a locust.*) The name applied by Fabricius to a genus of locusts, characterised by a carinate thorax; filiform antennæ, shorter than the thorax; and equal palps or feelers.

ACT. In Dramatic literature, a division of a drama, subdivided into scenes. The Greek dramas of the old model were naturally divided into separate portions by the stasima, or choric odes, which occur at intervals, during which the stage was left to the sole occupation of the chorus. Nevertheless, the Grecian writers do not notice this division in express terms; nor do we know the origin of the famous rule of Horace, that every dramatic piece should be restrained within the limits of five acts, neither more nor less. The division into acts must be in great measure arbitrary, although rules have been laid down, by various writers, to define the portion of the story or plot which should be contained in each of them. Thus, Vossius lays it down as a rule, that the first act presents the intrigue, the second develops it, the third is filled with incidents forming its knot or complication, the fourth prepares the means of unravelling it, which is finally accomplished in the fifth. (*See* DRAMA.)

ACT. In the Universities, an exercise performed by students before they are admitted to degrees. The student proposes certain questions to the presiding officer of the schools, who then nominates other students to oppose him. The discussion is syllogistical and in Latin, and terminates by the presiding officer questioning the respondent, or person who is said to keep the act, and his opponents, and dismissing them with some remarks upon their respective merits.

ACT OF PARLIAMENT. *See* STATUTE.

A'CTA DIURNA, *daily proceedings.* Among the various important improvements effected by Julius Cæsar may be ranked that of his furnishing the Romans with a species of newspaper. He was the first to order that the *acta diurna* of the senate and the people should be drawn up in a regular form and published. This publication must consequently have, in many important respects, closely resembled a modern newspaper. — (Sueton. in Cæs. cap. 20.)

A'CTA ERUDITORUM. The title of a celebrated literary and scientific journal, which was commenced at Leipzig, in 1682, by professor Mencke, of that university. The last volume was that for 1776.

A'CTIAN GAMES. (Lat. *Ludi Actiaci.*) Games celebrated in antiquity at Actium in honour of Apollo, hence surnamed *Actius.* The temple of the god was repaired, and the games restored and celebrated with increased splendour by Augustus, in memory of his victory over Mark Antony off Actium.

ACTI'NIA. (Gr. ἀκτιν, *a ray.*) A genus of polypi with very numerous tentacles, which extend, like rays, from the circumference of the mouth. They are amongst the most highly organised of the class, having the alimentary sac distinct from the parietes of the body; feeding on shellfish and other marine animals, which they draw into their mouth with their tentaculæ, and in a short time rejecting, through the same aperture, the shells and indigestible parts. They are of a soft gelatinous texture, and they assume various forms when the tentacles are all expanded, having the appearance of full-blown many-petalled flowers; whence they are called "sea anemones," "sea sunflowers," &c. (*Phil. Trans.* lxiii. p. 361.)

ACTI'NOCA'MAX. (Gr. ἀκτιν, *a ray*, καμαξ, *a pale.*) A name applied by Miller to the fossil shells of an extinct genus of Cephalopodous Molluscs, apparently connecting the *Belemnites* with the existing *Sepiæ*. The remains of the *Actinocamax* appear, as yet, to be peculiar to the chalk formations of England and Normandy.

ACTI'NOCRI'NITES. (Gr. ἀκτιν, *a ray*, κρινον, *a lily.*) The name of a subgenus of extinct Crinoidean radiated animals, or Encrinites, characterized by the numerous rows of angular plates, which, being articulated by their margins, constitute the body.

ACTI'NOLITE. (Gr. ἀκτιν, *a ray*, and λιθος, *stone.*) A variety of hornblende, which usually occurs in fascicular crystals.

ACTINO'METER. (Gr. ἀκτιν, and μετρον, *measure.*) An instrument invented by Sir John Herschel for measuring the intensity of the sun's rays. *See* PHOTOMETER.

A'CTION. (Lat. ago, *I act.*) In Painting and Sculpture, the state of the subject as imagined in the artist's mind at the moment chosen for representation. It must not be confounded with motion, which relates to the mobility of a single figure. Action must be true, simple, natural, and connected; and its unity must be preserved, or the action is weakened.

ACTION. In the Military Art, an engagement or battle between opposing forces; hence *partial* actions, *general* actions, &c.

ACTION. In Oratory, the accommodating or suiting of the countenance, voice, and gesture of the speaker to the matter to be spoken or delivered. This *sermo corporis*, as Cicero calls it, has always been regarded as a most important part of oratory. The ancient masters laid the greatest stress upon it. Demosthenes said that action was "the beginning, the middle, and the end of the orator's office;" and Cicero admits, that "*what* an orator says is not of so much importance as *how* he says it." Hamlet's advice to the players should be kept in mind by those who desire to excel in this art.

ACTION. In Poetry, an event either real or imaginary, forming the subject of an epic poem or play, &c. Thus the wrath of Achilles forms the action or subject of the Iliad, the wanderings of Æneas the action or subject of the Æneid, &c.

ACTION. In the Stock Market in Paris, and other places in France, *action* is the name given to a share of the capital stock of a joint stock company.

ACTION. In Mechanics, denotes sometimes the effort which a body or power exerts against another body, sometimes the effect or motion resulting from such effort. Mechanical action is exerted either by percussion or by pressure; in the former case the effect is instantaneous, in the latter it is continued. In all cases of mechanical action, the effect of the acting body is resisted in an equal degree by the inertia of the body acted upon, which resistance is termed reaction; and it is an axiom in mechanics, that action and reaction are always equal, and exerted in opposite directions. Thus, in driving a nail with a hammer, the stroke acts against the face of the hammer exactly with the same energy as against the head of the nail; and in pressing the hand against a stone, the pressure on the hand and on the stone is precisely the same.

A'CTIONS, in Law, are real, personal, or mixed. Actions, real or mixed, for the recovery of real property, are very numerous, but so prolix and difficult that they are almost wholly abandoned as a means of obtaining justice, and questions relating to title to land are now tried by the simple form of ejectment. The only case in which they have been resorted to, of late years, has been when, from the shorter period to which the action of ejectment was limited (*see* LIMITATIONS), a right survived for the purpose of the former, which was barred as to the latter. But the recent acts on this subject have much reduced the distinction. Actions in common use, *i. e.* personal actions, are also divided into actions of contract and actions of tort, and into local and transitory, in the former of which the place or county where the cause of the action arose must be accurately alleged, for the purpose of the trial taking place there. This allegation is termed the *Venue* of the action, from the Norman-French *visne*, vicinetum, neighbourhood, because the jury impanelled to try an action came originally from the neighbourhood. In the latter it is immaterial. Actions of tort to the person, and all actions of contract, are generally transitory, but under certain circumstances the latter may be local.

ACTI'VITY. The virtue or faculty of acting. The term is used in physics to denote the promptitude of the action of one body on another. Thus we speak of the activity of an acid, of poisons, of the electric fluid, &c.

Sphere of activity, the space within which the action of a body (of a magnet, for example) produces any sensible effect.

A'CTOR, ACTRESS. In the flourishing period of the early Greek drama, so long as a certain remnant of religious solemnity was attached to it, there was no degradation in the character of an actor: in fact, the parts of the chorus were often filled by volunteer performers of birth and station. But when the dramatic performers began to form a profession apart, they appear soon to have been regarded with disrespect. In Rome, the first actors were buffoons (known by the Tuscan name of *histriones*), who enacted the grotesque farces imported from Etruria, and the qualification of actor was among the most dishonourable in the period of the republic; and no circumstance was considered to indicate more decisively the intention of Nero to degrade and subject all classes in the state, than his having persuaded a Roman knight, Laborius, to appear on the stage in the performance of one of his own mimi. Under the dissolute reigns of the first emperors, especially Nero, much favour and countenance was shown to actors. Nero was, however, obliged at last to banish the *pantomimi*, the most popular species of actors, entirely from Italy, together with their performances, in consequence of the strong party spirit which was excited about them. (Sueton. Nero. c. 16.) It seems from Tacitus, that they were soon afterwards restored: again banished

by Domitian; restored by Nerva, and finally expelled by Trajan; but, by the time of the reign of the last-mentioned emperor, the dramatic stage was nearly abandoned, and its place wholly occupied, by gladiatorial shows and other pageants. In England, the first actors were the servants of great nobles, who performed for their diversion; and when regular theatrical companies were formed, they were long in the habit of putting themselves under the protection of distinguished personages: the companies of the greater theatres, as is well known, retain the custom of calling themselves servants of His Majesty. Actresses were not known on the English stage until some time after the Restoration: although ladies of quality had frequently, under James and Charles I., performed parts in masques, &c. Kynaston was the last celebrated male performer of female parts. A singular notice of him will be found in Pepys's Memoirs. In Roman Catholic countries, actors, even to this time, are under the ecclesiastical restriction of excommunication. (*See* DRAMA.)

ACTIVE MOLECULES. (*See* MOLECULES.)

ACTS OF SEDERUNT. (Scotch law.) Statutes made by the Lords of Session sitting in judgment, by virtue of a Scottish act of parliament, passed in 1540, empowering them to make such constitutions as they may think expedient for ordering the procedure and forms of administering justice.

A'CTUARY. Originally a public officer in the Roman courts of justice, who drew up writings, contracts, &c., in the presence of the magistrate; whence his name, from actus, *an instrument.* The clerk who registered the acts and constitutions of the convocation, in the assemblies of that body, was termed actuary. The managing officer of an insurance company is usually termed in England an actuary. (*See* INSURANCE.)

ACU'LEATE. (Lat. aculeus, *a prickle.*) In Botany, any thing covered with prickles; that is, with sharp prominences which originate in the cellular system and have no connection with wood.

ACU'LEATES. In Zoology, a tribe of hymenopterous insects, in which the females and neuters are provided with a sting, generally concealed within the last segment of the abdomen.

ACU'MINATE. (Lat. acumen, *the point of any thing.*) When a leaf or any other body is very much tapered to a point; it is thus distinguished from acute, which means sharp-pointed without any tapering.

ACUPU'NCTURA'TION. (Lat. acus, *a needle*, and punctura, *a puncture.*) Pricking with a needle. In the East this is a common remedy for painful affections of different parts of the body. It has lately been extensively practised here for the cure of chronic rheumatism, a long and sharp needle being thrust into the affected muscles.

ACU'TE. The opposite of obtuse. An acute angle is that which is less than a right angle; an acute-angled triangle is one of which each of the angles is acute; an acute-angled cone is one whose opposite sides form an acute angle at the vertex.

ACUTE. (Lat. acutus, *sharp.*) In Music, the height or pitch of a sound or tone, in respect of another. It is opposed to grave.

AD LI'BITUM. In Music (*at pleasure*), a term applied to an accompaniment which is not essential, and may or may not be performed without interfering with the composition.

AD QUOD DAMNUM. (Lat. *to what damage.*) A writ sued before the grant of certain liberties and franchises, as a fair, market, &c., which may be prejudicial to the king who grants, or the public; by it the sheriff is directed to inquire what damage may accrue from the grant in question.

ADA'CTYLE. (Gr. ἀ, priv. and δακτυλος, *a digit.*) In Zoology, signifies a locomotive extremity without digits.

A'DAGE. (Lat. adagium, *a proverb.*) (See PROVERB.) The proverbs of antiquity are collected by Erasmus in a work entitled *Erasmi Adagia.*

ADA'GIO. (Ital. adagio, *leisurely.*) In Music, the slowest of musical time, grave only excepted. (*See* ALLEGRO.)

ADAMA'NTINE SPAR. (Gr. ἀ, *without*, and δαμαω, *I break*, or *conquer.*) A variety of crystallised alumina, nearly resembling the sapphire in composition, and of extreme hardness. The finest specimens come from India and China. At Bombay it is called corundum.

A'DAMITES. (Theology.) A sect in the early ages of the Christian church who are said to have professed an exact imitation of the primitive state of innocence. They re-appeared in the 15th century in Bohemia. (*Mosheim*, I. p. 233, &c.)

ADANSO'NIA. A remarkable African tree, named after Adanson, a celebrated French botanist and traveller. It is called by the negroes *Baobab.*

A'DAPIS. A name originally applied by Gesner to the Hyrax or coney of Scripture, and adopted by Cuvier to designate another small pachydermatous quadruped, now extinct, but the existence and nature of which that great naturalist detected and deduced from three fragments of the head, which were discovered in that immense depository of fossil bones, the gypsum quarries of Montmartre. The dentition of the Adapis is as follows:— each jaw has four trenchant incisors; two conical canine teeth, the upper ones straight, the lower inclined obliquely forwards; and apparently fourteen molar teeth, of which the first is trenchant, and the three or four posterior ones, on each side, like the posterior molars of the Anoplotherium. Cuvier supposes the animal to have been about the size of a rabbit, and to have closely approximated the Anoplotheria.

A'DDER. (*See* VIPER.)

ADDI'TION. In Arithmetic. The operation by which a number is found equal to several others taken together. It is the first of the four fundamental rules. Addition, in algebra, is the uniting or incorporating of several algebraic quantities into a simple or contracted expression.

A'DDITIVE. Something to be added, in contradistinction to subtractive, which denotes something to be taken away. The terms additive and subtractive are sometimes applied to algebraic quantities, to denote those relations to other quantities which are more commonly, though less correctly, expressed by positive and negative.

ADDU'CTOR. (Lat. adduco, *I draw towards.*) The adductor muscles are opposed to the abductors: they draw the parts to which they are attached, together.

ADE'LPHIA. (Gr. ἀδελφος, *a brother.*) A collection of stamens into a bundle. Linnæus employed this term for those plants in which the stamens, instead of growing singly, combine into one or more parcels, or brotherhoods; thus, monadelphia signified stamens all connected into one parcel, diadelphia into two parcels, and so on.

ADE'NOSTY'LEÆ. (Gr. ἀδην, *a gland*, and στυλος, *a column*, or *style.*) A subdivision of composite plants, comprehending tussilago, liatris, eupatorium, and some other genera, in which the branches of the style are covered with long glandular hairs.

ADE'PHAGANS, ADEPHAGA. (Gr. ἀδηφαγος, *voracious.*) A family of carnivorous and very voracious coleopterous insects.

A'DEPT. (Lat. adipiscor, *I obtain.*) A distinctive term applied to those alchemists who were supposed to have attained the great object of their researches, or to have discovered the philosopher's stone.

ADFE'CTED, or AFFECTED. (*See* the latter term.)

ADHE'SION, (Lat. adhæreo, *I adhere*,) is a property of vegetable matter by which contiguous parts grow together; and is one of the causes of the great diversity of appearance in the organs of plants. Two opposite leaves grow together and form apparently one, through which the stem passes; several in a whorl adhere, and form an involucre; a number of petals adhere, and thus constitute a monopetalous corolla; several stamens adhere, and an adelphia is the result; some carpels contract an adhesion with one another, and form a compound fruit; finally, the calyx adheres to the sides of the ovary, and then seems as if it grew from the apex of it. Irregularity in flowers and fruit is also in many cases produced by the unequal manner in which adhesion takes place between similar parts; of the calyx, two of the sepals adhere into one parcel, and three into another; the result of which is a two-lipped calyx; the same thing occurs in the corolla, and elsewhere.

ADHESION. (Physics.) A term used to denote the force with which different bodies remain attached to each other, when they are brought into contact. Adhesion has often been confounded with cohesion; but the two terms are essentially distinct. Adhesion is the force with which two bodies of different kinds cling to each other when united; cohesion is that which unites the particles of a homogeneous body with each other. Thus, the particles which form a drop of water or quicksilver are united by cohesion; the particles of water which wet the surface of any body are united to it by adhesion.

Adhesion may exist between two solid bodies, between a solid and a fluid, or between two fluid bodies. The adhesion of solid bodies is exemplified in the force required to separate two pieces of marble, whose polished surfaces have been brought into contact. The suspension of water above its level in capillary tubes, or between two plates of glass very nearly in contact, shows the adhesion of a fluid to a solid body; and an instance of the adhesion of two liquids is obtained by covering a plate of glass with oil, and bringing it into contact with the surface of water; a very sensible force is required to raise it perpendicularly from the water.

Dr. Brook Taylor appears to have been the first who undertook to estimate experimentally the force of adhesion; and the method which he employed, was to determine the weight necessary to separate fir-boards from the surface of water. This method, however, unless proper precautions are taken, is apt to give inaccurate results. On separating a fir-board from water, the whole

surface of the board may be observed to be wetted; that is to say, a thin film of water remains attached to the wood, so that the force by which the separation was effected is not the force necessary to overcome the adhesion of the water to the board, but the cohesion of the particles of water to each other. This is fully established by the experimental fact, that, when discs of different substances are applied to a liquid, by which they are perfectly wetted, their adhesion to it is the same, whatever may be their nature, and exactly equal to the cohesive force of the fluid. Discs of glass and discs of copper of the same diameter adhere to water with precisely the same force.

The adhesion of discs to the surfaces of liquids is demonstrated by Laplace to be a capillary phenomenon, arising from the action of attractive forces which are sensible only at very small distances. Supposing the diameter of the disc to be known, and the height to which the same liquid rises in a capillary tube of the same matter, and of a given diameter, Laplace determined from theory the force necessary to detach the disc. The results of his determination, applied to different liquids, as water, oil of turpentine, and alcohol, at different densities, agreed exactly with the numbers found by M. Gay-Lussac, in a series of very accurate experiments on this subject. The perfect identity of the forces producing adhesion and capillary attraction, is also proved by the following experiment: — It is well known that the height to which fluids rise in capillary tubes depends on the angle which the fluid makes with the sides of the tube. But the surface of mercury covered with water in a capillary tube is exactly spherical; consequently, the angle which the mercury makes with the sides of the tube vanishes, and the force is reduced to zero. If, therefore, adhesion depends on a force of the same nature, it follows that, on applying a disc of glass to the surface of mercury, and covering them both with water, no force should be required to separate the disc, excepting what is necessary to overcome its weight. Now, this was found by Gay-Lussac to be exactly what takes place. When the mercury and disc were covered with water, no resistance was offered to their separation; without the interposition of the water, a weight of 296 or even 400 grammes was required to overcome the adhesion. (Laplace, *Mécanique Céleste*, tome iv. Biot, *Traité de Physique*, tome iv. p. 464.)

The adhesion of the polished surfaces of solid bodies is proportional to the extent of the surface, or to the number of points brought into contact. It was formerly believed that the resistance to separation in this case arises solely from the pressure of the atmosphere; but the difference of its amount in different substances proves this opinion to be erroneous; besides, it is found to be the same in a vacuum. (*See* CAPILLARY ATTRACTION.)

ADIA'NTUM. (Gr. ἀδιαντος, *dry.*) A genus of thin-leaved ferns, having their fructification in short marginal lines. The leaflets are usually wedge-shaped and placed upon slender shining petioles. One of the species (A. capillus veneris) was formerly employed in the manufacture of syrup of capillaire.

ADIA'PHORITES. (Gr. ἀδιαφορος, *indifferent.*) A name given to Melancthon, and the party that agreed with him, in submitting, in things indifferent, to an imperial edict. The controversy which gave rise to this name had its origin in the imposition by Charles V., in 1548, of an edict, styled the Interim, because it proposed to accommodate for a time the differences of the papists and protestants, until the whole matter could be set at rest by the authority of a council. The opposite side was maintained by Flavius and the primitive Lutherans; and in the debate which followed there were two principal questions: first, whether it is lawful to yield to the enemies of truth, even in matters which are not of themselves essential; and, secondly, whether, granting the affirmative, the points in which the Interim required compliance, and in which Melancthon yielded it, are properly indifferent. Those points related chiefly to the doctrine of justification by faith, in which Luther and his genuine followers went to a great extreme; while Melancthon, although ostensibly the head of the Lutheran church, after the death of the great Reformer, adopted much more moderate views. Out of this controversy a great variety of other debates were engendered, and from these quarrels many schisms and divisions among protestants derived their origin.

A'DIPOCE'RE. (Lat. adeps and cera, *fat* and *wax.*) A fatty substance produced by the decomposition of the flesh of animals in moist situations, or under water, resembling, in some of its properties, a mixture of fat and wax.

A'DIPOSE. (Lat. adeps, *fat.*) Unctuous, or containing fat. Adipose membrane is the cellular membrane in which fat is deposited.

A'DIT. (Lat. adeo, *I approach.*) A horizontal shaft or passage in a mine, either for access, or carrying off water.

ADJA'CENT ANGLE. In Geometry, an angle immediately contiguous to another, so that one side is common to both angles. It is more particularly used when the two angles, besides having a common side, have their other sides in the same straight line. In this case, the adjacent angle is the same as the supplemental angle.

A'DJECTIVE. (Lat. ad, *to*, and jaceo, *I lie.*) In Grammar, that part of speech which is annexed to substantives, to define more accurately the conceptions intended to be denoted by them. *See* GRAMMAR.

ADJECTIVE COLOURS. Colours which require to be fixed by some base or mordant, in order to be applied as permanent dye-stuffs.

ADJOURNMENT, in Parliamentary language, means a postponement of the sittings or proceedings of either House of Parliament from one time to another specified for its re-assembling. Adjournment differs from prorogation in this, that the latter is an act of royal authority, whereas the power of adjournment is vested in each house respectively, no definite limits being prescribed to it by the constitution. *See* PROROGATION.

ADJU'DICATION. In Scottish Law, the diligence (*i. e.* process) by which land is attached as security for payment of debt. Adjudication for debt is a species of mortgage, redeemable, except in the cases of what are termed general adjudications, or adjudications contra hæreditatem jacentem.

ADJU'STMENT. In Marine Insurance, the settlement of a loss incurred by the insured.

A'DJUTANT. A military officer, attached to every regiment, who relieves the major of part of his duty, and performs it in his absence.

A'DJUTANT-GENERAL. A staff officer, who is to the army what the adjutant is to a regiment. He assists the general, and distributes his orders.

A'DJUTANT-GENERAL OF THE JESUITS. A title given to certain fathers who resided with the general of the order.

A'DJUVANT. (Lat. adjuvare, *to help.*) In Medicine, a substance which assists and promotes the operation of others.

ADMINISTRA'TION. (In Law.) If a person die intestate as to his personalty, letters of administration are granted by the ordinary (*see* LAW, tit. ECCLESIASTICAL COURTS) to such person as is pointed out by the statutes 31 E. 3., and 21 H. 8. These empower the ordinary to grant these letters to the widow, if there be one, or next of kin, at his discretion. Of persons equally near in degree the ordinary may grant to which he please. If none of the kindred take out administration, a creditor may do it. When the will is made without the nomination of any executor, the ordinary grants administration cum testamento annexo. Where a person dies intestate, his personal property descends (subject to his debts) as directed by the statute of Distributions, 22 & 23 C. 2. c. 10., explained by 29 C. 2. c. 30. One-third goes to the widow; the residue in equal proportions to the children, or, if they are dead, to their representatives, i. e. their lineal descendants. If there are none of these, then the widow takes a moiety, and the next of kin in equal degree, and their representatives take the other; if there be no widow, they take the whole. But of representatives none are admitted among collaterals farther than the children of the intestate's brothers and sisters. The order of nearness of kin, with reference to the distribution of intestates' estates, is thus arranged according to the rules of the civil law — children, parents, brothers, grandfathers, uncles or nephews (and the females of each class respectively), and, lastly, cousins.

ADMINISTRATION. (Lat. administratio, *care of an affair.*) In its general sense means the conduct or management of any affair; but in this country the term is usually applied to the management of the public or national affairs by the government, which is thence called *the Administration.*

A'DMIRAL. A great naval officer, who has the same power and authority over the maritime forces of a state that a general has over its land forces; and who also tries himself, or appoints officers to try, maritime cases. There are three ranks of Admirals, the Admiral (or full Admiral), Vice Admiral, and Rear Admiral. Each of these again has three gradations, of red, white, and blue, the colours of the flags they bear. —The Admiral carries his flag at the main, the Vice at the fore, and the Rear at the mizen mast.

ADMIRAL, *Lord High.* The ninth great officer of state in England. The office has been usually given, at least since the reign of Henry IV., to some of the king's youngest sons, near kinsmen, or of the higher nobility. Since the reign of Charles II. it has been, with occasional exceptions, always in commission, and the commissioners are styled 'Lords of the Admiralty.' It was held by the late sovereign William IV., when Duke of Clarence, from 1827 to the following year.

A'DMIRALTY, the Board of Commissioners for executing the Office of Lord High Admiral, and having authority over naval affairs generally.

ADMIRALTY, *Court of.* In Law, is a court of record,

of which the proceedings are carried on, at least to a certain extent, according to the course of the civil law; although, as the judge may have in some cases the assistance of a jury, it has also a resemblance to the courts of common law. It has jurisdiction principally for the determination of private injuries to private rights arising at sea, or intimately connected with maritime subjects; and in most cases, to which its authority extends, it has concurrent jurisdiction, either with the common law courts, or those of equity. Suits may be instituted in this court for assault and battery at sea; for collision of ships; for the restitution of goods piratically taken not under colour of war. It has also an equitable jurisdiction between part owners of a ship, It adjudicates in suits for mariners' wages, and for pilotage. It has a peculiar jurisdiction in cases of bottomry bonds, and other deeds in the nature of a mortgage of the ship; having an exclusive power to grant warrants to arrest the ship itself. It has also jurisdiction in cases of salvage, and incidentally of wreck.

The prize court, which decides prize causes in time of war, is a separate tribunal, although usually presided over by the same judge as that of admiralty. To that able and philosophical jurist, Sir W. Scott (Lord Stowell), who sat in these courts (as well as the ecclesiastical) for many years during the late war, and after its close, the country is indebted, not only for the high character and value of these tribunals, but also for the light thrown on the difficult and important questions of national law, by the most profound and lucid decisions ever applied to that subject.

A'DNATE. (Lat. adnascor, *I grow to any thing.*) Is said when one organ grows to the face of another, and not to its apex, in which case it would be innate. This term is chiefly employed in speaking of anthers.

ADO'NIS. In Mythology. A beautiful youth, son of Cinyras, king of Cyprus, beloved by Venus, and killed by a wild boar, to the great regret of the goddess. It is, also, the name of a river of Phœnicia, on the banks of which Adonis, or Thammuz, as he is called in the East, was supposed to have been killed. At certain seasons of the year this river acquires a high red colour, by the rains washing up particles of red earth. The ancient poets ascribed this to a sympathy in the river for the death of Adonis. This season was observed as a festival in the adjacent country. Facciolati, *Lexicon;* Calmet, *Dictionnaire de la Bible*, art. *Thammuz.*) Milton has beautifully alluded to these circumstances: —

> "——— Thammuz came next behind,
> Whose annual wound in Lebanon allured
> The Syrian damsels to lament his fate
> In am'rous ditties all a summer's day:
> While smooth *Adonis* from his native rock
> Ran purple to the sea; supposed with blood
> Of Thammuz yearly wounded."
> *Parad. Lost*, I. v. 445.

ADO'NIC. (Gr. 'Ἄδωνις, *Adonis.*) A species of verse consisting of a dactyle and a spondee; as in Horace, lib. I. Od. ii. v. 5. *Terruit urbem, visere montes*, &c. It was invented by Sappho, and derived its name from being principally sung at the festivals in memory of Adonis. (Facciolati, *Lexicon.*)

ADO'PTER. A vessel with two necks placed between a retort and a receiver, serving to increase the length of the neck of the former.

ADO'PTION. (Lat. adopto, *I adopt.*) In the Civil Law, signifies the admission of a stranger to the rights and privileges of a son. Adoption was a common custom among the Romans, by whose law a relation, nearly resembling that of master and slave, was constituted between father and son; so that a child, adopted from one family into another, passed, in effect, from the power of his parent to that of his adopter. Adoption is said, in Justinian's institutes, to be of two sorts: the one, also called arrogation, where a person, independent of parental control, is adopted into a family by virtue of an imperial rescript; the other, where, by the authority of a magistrate, a child passes from one family to another. But unless the adopter possessed a certain right by blood over the person adopted (as a grandfather), the parental power of the father was not extinguished. Adoption exists in the jurisprudence of various countries, where derived from the civil law; as in the German states and in France: in the latter country, the person adopting must be one having neither children nor other legitimate descendants.

A'DRAGANT. Gum Tragacanth.

ADRI'FT. Not fastened; as a ship that has parted from her anchor, a boat that has broke from her ship, a gun from the ship's side, &c.

A'DVENT. (Lat. advenio, *I approach.*) The holy season, comprising four Sundays before Christmas. It begins on St. Andrew's day, the 30th of November, or on the Sunday next before or after it, according to the day of the week on which the 25th of December falls.

ADVENTI'TIOUS. (Lat. adventitius, *extraordinary.*) In Botany, when any thing appears out of the ordinary course of nature: if a bud appears where buds do not usually appear, it is adventitious. This term must not be confounded with abnormal, which is used when any thing is *constructed* out of the ordinary course.

A'DVERB. A word annexed to an adjective or verb, to define more closely the modifications of the quality or action denoted. *See* GRAMMAR.

ADVE'RSA. A medallic term, applied to two heads facing each other.

A'DVERSE. (Lat. ad, *to*, and verto, *I turn.*) In Botany, leaves are so called when they present their under surface to the sun.

ADVE'RTISEMENT. (Lat. adverto, *I attend to.*) In its general sense, means any information as to any fact or circumstance. But it is more particularly used to designate notices made by competent authority in the daily papers, and otherwise, of events of local or general interest, as the publication of new books, sales of estates and produce, meetings of creditors, formation and dissolution of partnerships, &c. Such notices, when inserted in the gazette, or in newspapers and literary works published in numbers, pay a duty of 1*s.* 6*d.* each for each time of insertion.

ADULA'RIA. A resplendent crystallised felspar, of a pearly lustre. The finest specimens came from Adula, at the summit of St. Gothard.

ADU'LT. (Lat. adultus, *grown up.*) In its general sense it means any thing grown up, or arrived at maturity. It is that period of human life that extends from youth to old age.

ADU'LTERY. (Lat. adulterium, a word of very uncertain derivation.) The sin of incontinence committed by a married person: adultery between two married persons is termed *double* by some jurists. By the law of Moses, adultery was punished by death, Lev. xx. 10., Deut. xxii. 22.; and passages in Proverbs (c. vi.) and Ezekiel (xvi. 38. 40.) prove that the law was observed in this respect down to the overthrow of the Jewish monarchy, as we know it to have been in the time of our Saviour. The mode of punishment was by stoning; but it is observable that this mode is not ordained in Deuteronomy, as it is for various other offences. The test or ordeal of adultery is detailed in Numbers v. 11—31. Under the Grecian and Roman republics adultery was variously treated; but the celebrated Lex Julia de Adulterio, under Augustus, punished it with banishment (deportatio vel relegatio), Tacit. lib. ii. Annal. It was not until the reign of Constantine, when some tincture of Judaism had been introduced into the state along with the establishment of Christianity, that the punishment of death was formally enacted for it. This penalty was again mitigated under Leo and Mareian; and by the laws of Justinian the adulterer was punishable with death, the adultress with flagellation, imprisonment, &c. But about the same period, the gradual increase of episcopal authority in civil cases seems to have drawn crimes of incontinence almost wholly within the cognizance of the ecclesiastical courts; and the canons contain a variety of directions on the subject of adultery. On the other hand, the jurisprudence of the Northern nations, which visited this as well as other crimes of freemen with very little severity, as mere offences against individuals, reduced the penalty in most of the Western kingdoms to a mere pecuniary one, sometimes attended with public disgrace or corporal punishment. The customs of the several French provinces contain a great variety of penalties and fines; at Castelnaudari, in the fourteenth century, the fine for adultery was fixed at "five sous only!" Such penalties, of course, fell rapidly into disuse; and in the sixteenth century we find it observed by a French civilian (quoted by Thuanus), that "it was never heard that any body had been punished for adultery in France." This observation is quoted by the historian when relating an event which created great sensation at the time, namely, the capital punishment at Orleans of two offenders by St. Cyr, the governor, a rigid Calvinist. The protestants of that sect, in France as well as in Scotland and England, made it their endeavour to introduce primitive severity of manners by severity of punishment. De Thou, the father, appears also to have made some efforts toward putting in force the laws against adultery: but from the time of the religious wars, penal cognizance of adultery may be said to have nearly ceased in France, although, by various arrêts (1637, 1701, &c.), besides the civil consequences of an action of adultery by husband against wife, the latter might be condemned to seclusion in a house of correction for two years, or more. In Geneva, Strasbourg, and other places where the reformed religion prevailed, a temporary strictness of law was introduced about the same period, but with little permanent effect. In England, by the old common law, mutilation was the punishment of this as well as other offences; but under the Plantagenets it became matter of ecclesiastical cognizance (except so far as civil consequences were concerned), and visited

only by the spiritual censure of the church. "The rules of the canon law," says a recent writer, "have manifested an indulgence towards this offence which is chiefly to be accounted for by reference to the constrained celibacy of its early compilers." But in 1650 the puritans, under Cromwell, succeeded in obtaining an ordinance by which adultery, as well as simple fornication, was made felony, without benefit of clergy; an absurd decree, which was soon repealed. In 1694, and again in 1801, the subject of adultery and divorce was discussed at length in parliament, but without producing any enactment. (See Tebbs's Essay on the Scriptural Doctrines of Adultery and Divorce, and on the Criminal Character and Punishment of Adultery, 8vo. Lond. 1822.) For the civil consequences of Adultery, *see* MARRIAGE, LAW OF.

A'DVOCATE. (Lat. advocatus, *he who is called in to plead in a court of law the cause of another.*) The original pleaders of causes at Rome were the patricians, who defended gratuitously their clients; but even before the downfal of the republic, the class had degenerated into a profession, its members receiving rewards for their services, although still among the most honourable of employments. But from the original gratuitous character of advocates arose the peculiar custom by which, among ourselves, the fees of barristers are still regarded as honorary, and cannot be recovered at law. In the later ages of the empire the advocati appear to have formed a distinct class from the jurisconsulti, or chamber-counsel, and to have much declined in reputation. In France the avocats, or counsel, form a separate order, of which each member is attached to a particular local court. The lord advocate, in Scotland, is a public officer, who prosecutes crimes before the court of justiciary.

ADVOW'SON. (Lat. advocatio, *a calling.*) Properly, the relation in which a patron (advocatus) stands towards the living to which he presents, i. e. the patronage of a church. The earliest provision for divine worship, in England and in other countries, was derived from the offerings of the laity, which were distributed by the bishop of each diocese among his clergy, whom he sent from place to place to preach and administer the sacraments. By degrees he was enabled, by the bequests of the faithful, and the customary offering of tithes, to subdivide his diocese, or parochia, as it was originally called, into various districts, and to build churches and establish permanent ministers in each. At the same time it became a common practice among the nobles to build and endow churches for the benefit of themselves and their own dependants; in which case they were allowed to present to the benefice, subject to the licensing power of the bishop and the canons of the church. Advowsons, in legal phraseology are either appendant, where immemorially annexed to a manor; or in gross, where they form separate subjects of property. If the patron of a rectory fails to present within six months after the vacancy happens, the right falls to the bishop; and by similar neglect on his part, to the archbishop, and thence to the king. The presentation is by letter to the bishop; institution, by an instrument registered in the bishop's court; and induction, which completes the incumbent's title, is performed by the archdeacon.

A'DYTUM. (Gr. ἄδυτον, *a recess.*) In Architecture, the secret dark chamber in a temple, to which none but the priests had access. It was from this part that the oracles were delivered. Seneca, in his tragedy of Thyestes, says,

> "Hinc orantibus
> Responsa dantur certa, dum ingenti sono
> Laxantur Adyto fata."

Among the Egyptians, the Secos was the same thing of which Strabo has given a description. The only well preserved adytum of the ancients is in the little temple at Pompeii. It is raised some steps above the level of the temple itself, and is without light.

Æ'DES. (Lat.) In architecture. A small temple consecrated to a god which was not afterwards dedicated by the augurs, from which circumstance, according to Varro, it was different from the templum. This distinction among the Romans in the early ages was afterwards lost, and the words were used indiscriminately.

ÆDI'CULA. (Lat.) A diminutive of the preceding.

Æ'DILE. The title of certain Roman magistrates, so called from their care of buildings (ædes). They were divided into two classes, distinguished by the epithets plebeian and curule. The two plebeian ædiles were, as their name imports, elected from the commonalty (plebs), and were subordinate to the tribunes of the commons, having jurisdiction over lesser causes, submitted to them by those magistrates. The two curule ædiles, so called from their privilege of giving judgment on ivory seats (sellæ curules), were originally elected from the patricians, but afterwards from both plebeians and patricians promiscuously. This magistracy was one of the most dignified in the state, and was allowed the use of the robe of honour (toga prætexta), and a certain precedence in the senate. The peculiar office of the ædiles was the superintendence of public works, markets, &c., in the city. They had also, particularly the curule ædiles, to exhibit public games, which they often did at a vast expense, in order to court popularity. Julius Cæsar added two other plebeian ædiles, called cereal, to inspect the public stores of provisions.

ÆGICE'REÆ. (Gr. αἲξ, *goat*, κερας, *horn.*) A division of myrsinaceous plants, the type of which is the genus ægiceras. It is distinguished by the absence of albumen; the species grow in maritime swamps in tropical countries, and have the embryo germinating within the pericarp, after the manner of mangroves.

Æ'GIS. (Gr. αἲξ, *a goat.*) The mythological shield of Jupiter, which was covered with the skin of the goat Amalthæa, and given by him to Minerva, who, by fixing on it the head of Medusa, gave it the power of petrifying all persons who looked at it. The word is also used sometimes for the breast-piece of a god.

Æ'GYLOPS. (Gr. αἲξ, *a goat*, and ὤψ, *an eye.*) A sore in the inner angle of the eye, frequently terminating in fistula lachrymalis. Goats were supposed to be very subject to an analogous affection. — Also the name of a kind of grass.

Æ'NEID. The epic poem of Virgil, relating the wanderings of Æneas after the capture of Troy, and his settlement in Italy.

Æ'OLIPILE. (Lat. Æolus, *the god of the winds*, and pila, *a ball.*) An hydraulic instrument, contrived for the purpose of exhibiting the convertibility of water into steam. It consists of a hollow ball of metal, having a slender neck or pipe, with a very small orifice inserted into it. The ball, having been filled with water, is placed over the fire; and the heat gradually converts the water into vapour, which rushes out of the pipe with great violence till the whole is discharged. The experiment is not unattended by danger; for should the small orifice by any accident be stopped, the steam would burst the ball. The æolipile was known to the ancients, being mentioned by Vitruvius. Descartes and others have used it to account for the natural cause and production of the wind; hence its name, Æolipile, that is, pila Æoli, the ball of Æolus, the god of the winds. The æolipile is sometimes filed with alcohol, and the jet of its vapour being inflamed, it serves the purpose of a blowpipe.

Æ'OLUS. The god of the winds, who was fabled by the early poets to have his seat in the floating island of Æolia; but the Latin and later Greek poets placed him in the Lipari isles. Here the winds were pent up in vast caves, it being the duty of Æolus to let them loose, and to restrain their violence at the pleasure of Jupiter. Virgil has described the power and functions of Æolus, in one of the finest passages of the Æneid: —

> —— "Hic vasto rex Æolus antro,
> Luctantes ventos tempestatesque sonoras
> Imperio premit, ac vinclis et carcere frænat.
> Illi indignantes magno cum murmure montis
> Circum claustra fremunt. Celsâ sedet Æolus arce
> Sceptra tenens, mollitque animos, et temperat iras:
> Ni faciat, maria ac terras cœlumque profundum
> Quippe ferant rapidi secum, verrantque per auras."
> *Æneid*, I. l. 52.

ÆOLUS' HARP, or ÆOLIAN HARP. A well-known instrument, which produces a pleasing combination of sounds, by the action of the wind. Its construction is very simple, consisting of merely a number of catgut or wire strings, stretched in parallel lines over a box of thin deal, with sounding holes cut in the top. The strings being tuned in unison, the effect is produced by placing the instrument in a current of air. The invention of the Æolian harp is generally given to Kircher, by whom it was first described.

Æ'ON. *See* GNOSTICS.

Æ'RA, or ERA. (A word of doubtful derivation.) In Chronology, the term æra, as now understood, is the period that has elapsed from some fixed point of time, or epoch, called the commencement of the æra. — Thus the Christian æra began at the birth of Christ, the Mohammedan æra at the flight of Mohammed from Mecca to Medina, the æra of Diocletian at the coronation of that emperor, &c.; and the period of the occurrence of any event is ascertained by reckoning from one or other of these epochs. When, for example, it is said that Queen Victoria ascended the throne of Great Britain in 1837, it means that this event took place in the 1837th year of the Christian æra, or of that æra which began with the birth of Christ. It is plain from the above statement that the period of time selected for an æra, or point whence to begin the computation of time, is necessarily arbitrary; and different nations have adopted different periods coincident with some important event in their civil or religious history. Some have adopted the year of the creation of the world, and this, were its date well ascertained, would be one of the best that could be selected. But the sacred writings are not explicit on this point, and there are great discre-

pancies in the estimates, as to the period of its occurrence. The Greeks used to reckon by the æra of the Olympiad (*see* the word), which began at the summer solstice, anno 776, B. C. The Romans reckoned from the building of the city, generally held to be the 24th of April, B.C. 753. The Julian æra dates from the reformation of the calendar by Julius Cæsar, B. C. 45. All Christian nations now adopt for their æra the birth of Christ, which took place on the 1st of January, in the middle of the 4th year of the 194th Olympiad, and the 753d year of the building of Rome. The æra of most Mohammedan nations is that of the Hegira, or flight of Mohammed to Medina, corresponding with the 16th July, A. D. 622. The æra of Sulwanah, in common use in a great part of India, corresponds to A. D. 78. The æra of Yezdegird, used in Persia, began 16th June, A. D. 632.

Subjoined are the names of some of the principal æras, with the year of the Christian æra in which they began, and the abbreviations by which they are commonly distinguished.

Æras.	Commenced	Abbreviations
Year of the World (Constantinopolitan account) -	B. C. 5,509	A.M. Const.
— (Alexandrian account)	— 5,492	A.M. Alex.
— (Jewish account) -	— 3,760	A.M.
Æra of Nabonassar - - -	— 747	Ær. Nab.
Olympiads - - -	— 776	Olymp.
Year of Rome - - -	— 753	A. U. C.
Julian Æra - - -	— 45	Jul. Ær.
Christian Æra - - -	— —	A. D.
Æra of Sulwanah - -	A. D. 78	Saca.
Æra of Dioclesian - - -	— 284	Ær. Dioc.
The Hegira - - -	— 622	A. H.
Æra of Yezdegird - - -	— 632	A. Pers.

It is easy to deduce from this the year of the Christian æra corresponding with that of any greater æra. (*See further* Chronology of History by Sir H. Nicholas, p. 22, &c.)

ÆRA'RIAN. The term applied to a Roman citizen who had been degraded to the lowest rank compatible with personal freedom. He, however, still paid taxes, but enjoyed no privileges, and could not serve in the army, or, consequently, participate in the distribution of land granted to such classes as did.

ÆRA'RIUM. (Lat.) The public treasury of the Roman people, the care of which was vested in the quæstors. After the fall of the republic the ærarium was kept distinct from the treasury of the emperor, which was called fiscus. The ærarium sanctius, or more sacred treasury, was appointed to provide for cases of extreme emergency, and might not be opened on other occasions.

AE'RIAL. (Gr. ἀηρ, *air.*) In Painting, a term applied to the diminishing intensity of colour on objects receding from the eye. Aerial perspective is the relative apparent recession of objects from the foreground, owing to the quantity of air interposed between them and the spectator, and must accompany the recession of the perspective lines.

AERIAL ACID, *Carbonic acid.*

A'ERO-DYNA'MICS. (Gr. ἀηρ, and δυναμις, *power.*) The science which treats of the motion of the air, and of the mechanical effects of air in motion. This is an experimental science, and there are two ways in which it may be investigated. The first is, by ascertaining the effects which air, moving with a certain velocity, that is, wind, produces on a body against which it strikes; and the second, by ascertaining the resistance which air at rest offers to a solid body rapidly passing through it. The problem is exactly the same, whether the body is considered as moving against the air at rest, or the air is supposed to move against the body with the same velocity.

Conceive a body to be moved forward in a straight line, displacing successively the particles of air opposed to it; the effect which it produces is proportional to the number of particles against which it strikes, and to the quantity of motion communicated to each. Suppose now the velocity of the body to be doubled, the motion communicated to each particle of air displaced will be twice as great as before, and twice as many particles will receive the impulsion in the same time. Hence we infer that the effect will be four times as great, or that the effect is proportional to the square of the velocity. This result of theory agrees tolerably well with experiments made to determine the resistance of the air when the velocity is not very great, or not exceeding eight or nine hundred feet in a second. When the velocity is much greater than this, the effect is modified by circumstances which require further explanation.

When a solid body is moved out of its position, the space which it occupied is not filled with air instantaneously, but only after a sensible, though very short time. Theory, confirmed to a certain degree by experience, shows that air, under the ordinary atmospheric pressure, rushes into a vacuum with a velocity of between 1300 and 1400 feet in a second of time. But this velocity is very speedily checked; for the instant that any portion of air is admitted, or the vacuum ceases to be perfect, that portion resists the entrance of more with a force proportional to its density. Suppose, for example, the air in a receiver to be reduced to one-fourth of its natural density; the effort of the exterior air to enter the receiver will be reduced to three-fourths of its amount when the receiver was perfectly exhausted; and consequently the velocity, which is proportional to the square root of the effort or the resistance, will be reduced in the proportion of 1 to $\sqrt{\frac{3}{4}}$; or of 100 to 87, very nearly. In this manner, as the air continues to enter, the velocity will rapidly diminish.

Now, conceive a body, for example a cannon ball, to be moving rapidly through the air, but with a less velocity than 1300 feet per second. The air in front of the ball will remain in its natural state, because the condensation produced every instant by the contact of the ball, is propagated more quickly than the ball moves (the velocity of the propagation being equal to that with which air enters a vacuum). But there is a certain space behind the ball in which the air has not entirely recovered its equilibrium, but remains more or less rarefied, the ball having passed through it in less time than is required for the surrounding air entirely to fill it. In addition, therefore, to the resistance which arises from the communication of motion to the particles of air, there is a pressure on the front part of the ball, not counterbalanced from behind; in consequence of which, we may infer that the resistance will increase in a quicker ratio than the square of the velocity. This deduction is also confirmed by experience; for it is found that the resistance continues to increase with the square of the velocity only while the velocity is less than 900 or 1000 feet per second. Above this velocity the ratio begins to fail; and when the velocity exceeds that with which air enters a vacuum, the ratio is entirely altered. At a velocity of 1600 feet per second, the resistance is found to be more than twice that given by theory. The reason is obvious: the density of the air before the body is increased by the rapid motion, and, consequently, presses more on the fore part of the body than air in its natural state.

The resistance of the air on the motion of projectiles, was first examined experimentally by M. Robins (see his Principles of Gunnery), and afterwards by Dr. Hutton, of Woolwich (see his Tracts, vol. 3., and Math. Dictionary), whose experiments were carried on to a greater extent, and varied in a greater number of ways. The following are the principal results deduced by Dr. Hutton, from his experiments on bodies moving very slowly, not more than 20 feet per second:—

1st, " That the resistance is nearly in the same proportion as the surfaces; a small increase only taking place in the greater surfaces and for the greater velocities.

2d. " The resistance of the air to the same surface with different velocities, is, in these slow motions, nearly as the square of the velocity, but gradually increases more and more above that proportion as the velocity increases.

3d. " The round ends and sharp ends of solids suffer less resistance than the flat or plane ends of the same diameter; but the sharper end has not always the less resistance.

4th. " When the hinder parts of bodies are of different forms the resistances are different, though the fore parts be exactly alike and equal; owing, probably, to the different pressures of the air on the hinder parts."

Dr. Hutton likewise found, that although in slow motions the experimental resistance is nearly equal to that computed by theory, yet, " as the velocity increases, the experimental resistance gradually exceeds the other more and more, till, at the velocity of 1300 feet, the former becomes double the latter; after which, the difference increases a little further, till, at the velocity of 1600 or 1700 feet, when that excess is the greatest, and is rather less than 2 and 1-10th; and, after this the difference decreases gradually, as the velocity increases; and at the velocity of 2000 the former resistance again becomes just double the latter." For further information on this subject, *see* PROJECTILES, WIND.

AERO'GRAPHY. (Gr. ἀηρ, *the air*, and γραφω, *I write.*) The description of the atmosphere, its nature, properties, limits, &c. (*See* ATMOSPHERE.)

A'EROLI'TE. (Gr. ἀηρ, *the air*, and λιθος, *a stone*, *stones of the air.*) The origin of these singular substances is involved in the greatest mystery. Some philosophers, among whom is Laplace, the illustrious author of the " Mécanique Céleste," suppose them to be ejected from volcanos in the moon; others suppose them to exist ready formed in the celestial space, circulating about the sun with great velocity, like planets, and falling to the earth when its attraction upon them preponderates; others regard them as fragments of rocks which have been propelled by terrestrial volcanos to an immense height above the limits of the atmosphere, and again descend after having described several revolutions about the earth.

On examining and comparing the aerolites, the first circumstance that strikes us as remarkable is their perfect resemblance to one another in their composition, whatever be their form or magnitude. Their exterior surface is black, as if they had been exposed to the heat of a furnace. Internally they are of a greyish white. Their specific gravity, which is very nearly the same in all of them, varies between 3·352 and 4·281, that of water being taken as unit. Their chemical analysis gives, in almost every instance, the same substances, combined in very nearly the same proportions. They are composed of silex, magnesia, sulphur, iron in the metallic state, nickel, and some traces of chrome. Sometimes they are formed of a spongy or cellular texture, the cavities being filled with a stony substance. They have occasionally been found without nickel. These common and constant characters indicate with the greatest evidence a common origin, and their composition renders it probable that it is to be sought elsewhere than in the earth. Iron is scarcely ever found (if, indeed, it is found at all) in the metallic state in terrestrial substances; volcanic matter contains it only in the state of an oxide. Nickel is also very rare, and never found on the surface of the earth; and chrome is still more rare.

The fall of the aerolites is accompanied by meteors, named bolides, or fire balls. They are, in fact, inflamed globes, which appear instantaneously in the atmosphere, and move through it with extreme velocity, sometimes even equal to that of the earth in its orbit. The direction of their motion is inclined to the horizon. After shining with great splendour for a few instants, they explode with a loud noise, and often at a great height, 30 or 40 miles above the surface of the earth. They do not affect any peculiar direction with respect to the motion of the earth, but seem to come from all points of the heavens indifferently.

With regard to the hypothesis which explains the origin of the aerolites, by supposing them to be propelled from lunar volcanos, it may be remarked, that no improbable amount of mechanical force would be required. As there is no atmosphere about the moon sufficient to offer a sensible resistance to the motion of a solid body, the force required is only that which would be sufficient to overcome the moon's attraction, which is found by calculation to be about four times the force with which a ball is expelled from a cannon with the ordinary charge of gunpowder. A body projected with a velocity of about 7770 feet per second from the lunar surface, would be detached from the moon, and be brought to the earth by terrestrial gravitation. But philosophers seem now disposed to assign the aerolites a different origin. From the phenomena of comets there is reason to believe that portions of chaotic matter are dispersed in the planetary regions in detached parcels, or perhaps in considerable masses. The earth in describing its orbit may meet with such masses directly, or pass so near to them as to carry them along with it by virtue of its attraction. On plunging into the atmosphere with the velocity due to the height from which they have fallen, which is that of their distance from the earth, when they begin to obey its attractive force, an enormous heat is evolved by the rapid and powerful condensation of the air; the matter becomes inflamed, and the aerolite is the product of the combustion. In the same manner shooting stars, and other igneous meteors of frequent occurrence, are explained. The chaotic matter may be entirely consumed long before it reaches the earth, in which case the appearance of the bolide will not be accompanied with the fall of an aerolite. (*See* METEOR.)

Philosophers were long inclined to disbelieve in the fall of stones through the atmosphere. The fact, however, is now placed beyond all doubt by numerous and well authenticated instances which have occurred in almost all quarters of the world, even within the present century. A very complete list of the falls of stony or earthy matters, with the times and places of their occurrence, and the appearances they exhibited, is published in the Edinburgh Philosophical Journal, from a work by Chladni, in German, in which the whole subject of meteoric stones is ably and fully treated.

AERO'LOGY. (Gr. ἀηρ, *air*, and λογος, *a discourse.*) The doctrine of air, generally applied to medical discussions respecting its salubrity.

AERO'METER. (Gr. ἀηρ, *air*, and μετρον, *a measure.*) An instrument for making the necessary corrections in pneumatic experiments, to ascertain the mean bulk of gases

A'ERONAUT. (Gr. ἀηρ, *air*, and ναυτης, *a sailor.*) One who travels in a balloon.

A'ERONAUTICS. (Gr. ἀηρ, *air*, and ναυτικος, *of or belonging to ships.*) The art of sailing in and navigating the air. From the earliest ages men have been actuated by a wish to be able to participate in the advantages conferred on the lower animals, and having succeeded in navigating the sea, to be able also to mount, like the eagle, into the air. The story of Dædalus, who is said to have escaped from Crete to Sardinia, by means of wings contrived to assist him, is known to every classical reader, and proves, at least, the antiquity of attempts of this sort. But the fate of his companion Icarus, seems to have had a greater influence in deterring from similar attempts, than the reported success of the artificial dove, constructed by the geometer Archytas, which is said to have wafted itself through the air by means of internal springs. During the middle ages, when the nature of the atmosphere and the sound principles of mechanical philosophy were alike unknown, many rude and necessarily unsuccessful attempts were made to realize this difficult problem. But it was not till the composition of the atmosphere had begun to be ascertained, and that means had been devised of filling vessels with heated air, or other air lighter than atmospheric air, and consequently capable of floating on it, that there came to be a rational prospect of succeeding in the "audacious attempt" of riding in the air. At length, in 1782, the brothers Montgolfier succeeded in constructing a balloon; and on the 21st of October, 1783, Pilatre de Rozier, a young naturalist, and the Marquis d'Arlandes, ascended from Paris to an elevation of more than 3000 feet, and alighted safely from their "ærial tour," after describing a circuit of about six miles. Since that time ascents in balloons have become comparatively common. (*See* BALLOON, and the article Æronautics in the *Encyclopædia Britannica*, 7th edit.)

A'EROPHY'TES. (Gr. ἀηρ, *air*, and φυτον, *a plant.*) Plants which live exclusively in air; in distinction to hydrophytes, which live as constantly under water.

A'EROSTA'TICS. A term sometimes used to denote the science which treats of the equilibrium of elastic fluids. (*See* PNEUMATICS.)

A'EROSTA'TION. (Gr. ἀηρ, *air*, and σταω, *I stand.*) Means simply the weighing of the air; but it has been employed, though incorrectly, in the science of æronautics, or as the art of raising substances into the atmosphere by the buoyancy of heated air, or of very light gases enclosed in a bag of a spheroidical form; hence called a balloon, which see.

ÆSCULA'CEÆ. A natural order of exogenous plants, consisting of the horse-chesnut, Æsculus hippocastanum, and other nearly allied species. They are all either shrubs or trees inhabiting temperate regions, and nearly correspond with Æsculus hippocastanum in the structure of the flowers. Their seeds contain starch, and their bark is in some cases bitter and astringent.

ÆSCULA'PIUS, or ASCLE'PIUS, as he was called by the Greeks, was a mythological deity of the Greeks and Romans, according to whom he was the son of Apollo and the nymph Coronis. He was worshipped as the god of surgery and medicine; but the older poets, as Homer and Pindar, mention him only as a hero well skilled in these arts. The chief seat of his worship was Epidaurus, where he was represented as an old man, with a mantle and staff, round which a serpent is twined.

AESTHE'TICS. (Gr. αισθητικος, *having the power of perception by means of the senses.*) In the fine arts, that science which derives the first principles in all the arts from the effect which certain combinations have on the mind, as connected with nature and right reason. It is intimately related to sentiment, which links together with feeling the different parts of a composition. All art, considered as imitation of nature, is affected by the same relations, and subject to the same laws, which govern nature herself; and if it could be satisfactorily proved that those rules of art which are the result of reason were necessarily connected with sensation, it might be possible to lay down laws from which the principles of art might be satisfactorily deduced. As an illustration of this, in architecture we might take the rule which forbids the position of a heavy mass over a void, when it may appear to have no ostensible and immediate support; in which case it might almost seem possible to connect the unpleasant sensation produced on the mind with the rules of reason; but in architecture it is difficult to conceive how this could be effected, without recurring to primitive types, and on them pursuing the reasoning into all its details. In the other arts it might not, perhaps, be so difficult to establish a set of rules, inasmuch as the immediate type is nature herself. The Germans have written much on the doctrine of aesthetics; it would, however, seem, that the fundamental principles of taste in all the arts depend on the laws of gravitation, and their balances, equipoise and counterpoise; the necessary resultants whereof are symmetry and proportion. We shall here lay before the reader a synoptical view of this science: to do more would occupy a space much more than would fill this volume; for, under other names, it is a subject which has much engaged the attention of writers on the philosophy of the arts. The essence of the polite arts lies in expression, or the power of representation, whether by lines, words, or other media, and that expression arises from an exercise of the inventive faculty; their end being the production of pleasurable sensations; thus being distinguished from the end sought in the sciences, whose object is to produce instruction and utility. And here we are to observe, that though

in some of the polite arts, such as eloquence, poetry, and architecture, the end may be to instruct, or to be applicable to useful objects, yet that the expression on which they depend brings them within the laws which govern the fine arts. The object of the fine arts is beauty, which is the result of all the various perfections whereof an object is susceptible: such perfections arising, first, from the agreeable proportions between the several parts of the same object; and, second, from the proportions between each part and the object taken as a whole. Genius, or the power to invent, is the faculty of the mind by which it is enabled to conceive and express its conceptions, and is, consequently, necessary to the production of beauty; while taste, or the natural sensation of a mind refined by art, is the guide to genius in discerning, embracing, and producing beauty. Hence a general theory of the polite arts must be founded on a knowledge of all that they contain truly agreeable and beautiful. They are usually said to include eloquence, poetry, music, painting, sculpture, and architecture. By some, dancing has been added to the number; but, for reasons too long to be advanced here, we cannot include it. The rules have been reduced to six, for the guidance of the artist, who is to recollect that, in every art, what is low, indecent, or disagreeable, must be banished from his work. First, he must consult his genius —

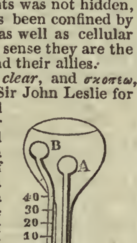
Quid ferre recusent,
Quid valeant humeri;

second, he must constantly labour to improve his taste; third, nature must be the constant object of his imitation; fourth, he must attain perspicuity, so that his end may be free from ambiguity and obscurity; fifth, he must elevate his sentiments above all common or commonplace objects, by which an expansion of the imagination supervenes and stamps his works with an air of sublimity, which, sixthly, results from a concurrent observance of the fourth and fifth rules. We close this with the following observation of Menzel: "Art is not the result of understanding alone; the inspiration of the artist has been, and ever must be, the source of that which gives æsthetic value to his productions."

ÆSTHNA. A name applied by Fabricius to a genus of dragon-flies, characterised by having the wings expanded when at rest, and the divisions of the lip equal.

AE'THEO'GAMOUS. (Gr. ἀηθης, *unusual*, and γαμος, *marriage.*) A name contrived to express more clearly the nature of what are called cryptogamic plants; it being the opinion of the author of the name that the mode of propagation among such plants was not hidden, but only of an unusual nature. It has been confined by De Candolle to such as have vessels, as well as cellular tissue, in their organisation. In this sense they are the same as ferns, lycopodiums, mosses, and their allies.

Æ'THRIOSCO'PE. (Gr. αιθριος, *clear*, and σκοπεω, *I view.*) An instrument invented by Sir John Leslie for measuring the relative degrees of cold produced by the pulsations from a clear sky. It consists merely of a differential thermometer, adapted to the cavity of a spehroidal cup of metal, the interior of which is highly polished, in such a manner that one of the balls occupies a focus of the spheroid; while the orifice of the cup is formed by a plane passing through the other focus, perpendicular to the axis. A lid of the same metal is fitted to the mouth of the cup, and only removed when an observation is to be made. Suppose the cup exposed to a clear sky: the cold pulses darted from the upper regions of the atmosphere, which enter the orifice of the cup, are reflected from polished surface upon the ball A in the focus, while the ball B, lodged at the side of the cup in its widest part, is nearly screened from them, or receives only the small number which fall obliquely upon it. The two balls are thus exposed to different degrees of cold, the effect of which is immediately apparent, by the rise of the liquor in the stem of the thermometer, in consequence of the contraction of the air in the ball A. The effect may be augmented by covering the ball B, which is out of the focus, with a coat of gold or silver leaf. It is evident that the instrument is equally adapted to measure the effects of the radiation of heat, which will be manifested by the descent of the liquor in the stem. When applied to this purpose, however, the metallic cup becomes unnecessary; the hot pulses being mostly thrown back from the bright surface of the gilt ball, while they produce their full effect on the naked or sentient one. The æthrioscope is thus converted into a pyroscope. (See *Encyc. Brit.* article Climate.)



ÆSTIVA'TION. (Lat. æstivus, *of or belonging to summer.*) A figurative expression, employed to indicate the manner in which the parts of a flower are arranged before they unfold. Botanists speak of the æstivation of the calyx, of the corolla, of the stamens.

Æ'STUARY. (Lat. *Æstuarium.*) In Geography, was anciently understood to be any creek, frith, or arm of the sea, in which the tide ebbs and flows (Plin. Epist. lib. 9. ep. 33.); but it is now applied to designate those parts of the channels of certain rivers contiguous to the sea in which the water is either salt or brackish, and in which the ebb and flow of the sea is distinctly perceptible, and there is little or no current.

Æ'THER. *See* ETHER.

A'ETIA'IOI. (Gr. αετος, *an eagle.*) In Architecture, the name given by the Greek architects to the slabs forming the face of the tympanum of a pediment. This word occurs in the Athenian inscription now in the British Museum, brought to England by Dr. Chandler, and relating to the survey of some temple at Athens.

ÆTIO'LOGY. (Gr. αιτια, *a cause*, and λογος, *discourse.*) The doctrine of the causes of disease.

AETO'MA, or A'ETOS. (Gr. αετος, *an eagle.*) In Architecture, the name given by the Greek architects to the tympanum of a pediment. It seems to have derived its name from the custom of decorating the apex or ridge of the roof with figures of eagles, and that the name thence first given to the ridge was afterwards transferred to the pediment itself.

AFFECTA'TION. (Lat. affectare, *to seek for overmuch.*) In the fine arts, an artificial show arising from the want of simplicity either in colouring, drawing, or action. Also, the overcharging any part of a composition with an artificial or deceitful appearance.

AFFE'CTED, or ADFECTED. A term of algebra. When applied to an equation, it signifies that two or more several powers of the unknown quantity enter into the equation: thus, $x^3 - ax^2 + bx - c = o$, in which there are three different powers of x, namely, x^3, x^2, and x. When the term is applied to a quantity, it implies that the quantity has a coefficient, or a proper sign: thus, in the quantity $+ 2x$, x is said to be affected with the coefficient 2, and with the sign $+$. Dr. Hutton thinks the term affected was introduced into algebra by Vieta.

AFFE'TTO, or AFFETTUOSO. (It. affetto, *affection.*) In Music, a term prefixed to a movement, showing that it is to be performed in a smooth, tender and affecting manner, and, therefore, rather inclining to slowness than the reverse.

AFFIDA'VIT. (Lat. affido, *I confirm by oath.*) In Law, is an oath in writing, sworn before some person who has authority to administer it.

AFFILIA'TION. (Lat. ad, *to*, filius, *a son.*) In Law, the assignment of a child to a parent by legal authority; as where the father of a bastard child is designated on the testimony of the woman, and the expenses of maintaining it cast upon him. By the Poor Law Amendment Act, s. 72., this can now only be done, after sufficient notice to the party intended to be charged, by an order of the court of quarter sessions, on the testimony of the woman, corroborated as to some material fact by other evidence. (See BASTARD.) *Affiliated societies*, in politics, are local societies, depending on a central society with which they correspond, and from which they receive directions. Such were the provincial jacobin clubs, founded on the model of the jacobin club of Paris. Such, also, were the corresponding societies in England, for the suppression of which the statute 39 G. 3. c. 79. was chiefly passed.

AFFI'NITY. (Lat. affinis, *related.*) A relation of animals to one another, in the similarity of a greater proportion of their organisation: thus, a porpoise is said to have an affinity to man, because of its resemblance to him in the respiratory, circulating, and generative systems, in the brain, eye, and ear, &c.; while it is said to have an analogy to a fish, because the resemblance is confined to external form. In short, affinity is that degree of relationship by which, in forming a concatenated series of animals, we pass from one to another by the closest gradations.

AFFINITY, CHEMICAL. The attractive force by which dissimilar substances combine with each other to produce chemical compounds. All natural and artificial substances are either simple or compound. The metals, for instance, are simple substances, — no one of them having been as yet decomposed: water is a compound; it may be resolved into oxygen and hydrogen gases, which are therefore called its component parts. To enable substances to exert their mutual affinities, or to act chemically upon each other, the opposing powers of matter must be overcome, and they must be placed under circumstances favourable to the exertion of their mutual chemical attractions. Two solid bodies seldom combine, in consequence of their imperfect contact, and the immobility of their particles; hence the old axiom, *corpora non agunt, nisi fluida.* But to this there are exceptions: ice and salt, for instance, run down into liquid brine; oxalic acid and dry lime unite; and when sulphur and chlorate of potash are rubbed together, they act violently on each other. Even when one or both substances are fluid, heat is often requisite to diminish cohesion, and promote affinity: thus, mercury and iron combine with melted sulphur; and oxygen and hydro-

gen, and oxygen and carbon, require heat to effect their union. In some cases the action of the solar rays excites and increases affinity, as in the combination of hydrogen and chlorine.

The investigation of the relative proportions in which bodies combine, forms the basis of the atomic theory, or doctrine of chemical equivalents.

Many substances seem to unite in all proportions; but these are not strict cases of chemical combination: thus, water and sulphuric acid, and alcohol and ether, mix together in any quantities. Others unite indefinitely, up to a certain point: water, for instance, dissolves salt, in variable quantity, till the solution is saturated: we thus find that a given quantity of water is only able to retain a certain weight of salt in permanent solution. In these cases of indefinite combination, the affinities of the combining substances are usually feeble; but where their affinities or attractive powers are energetic, there is a remarkable tendency to combine in certain proportions only. Thus, sulphuric acid and lime unite in the proportions of 40 of the acid to 28 of the lime, and in no other or intermediate quantity: in such cases the acid and the base are said to neutralise each other; and such compounds are often called neutral salts, that is, salts in which the leading characters of the component parts are no longer perceptible, which are neither acid nor alkaline. When such bodies combine in more than one proportion, which is often the case, the second, third, &c. proportions are simple multiples of the first: thus, 16 parts of sulphur combine respectively with 8, 16, and 24 of oxygen; in these compounds the relative proportions being as 1, 2, and 3. Again, 14 parts of nitrogen combine with 8, 16, 24, 32, and 40 of oxygen, forming five distinct compounds, in which the relative proportions of the oxygen are as 1, 2, 3, 4, and 5.

Where the combining substances are either naturally gaseous, or where they may be hypothetically so considered, it is obvious that, as their weights bear these simple relations to each other, their bulks or volumes will do so likewise: thus, in the case of the compounds just noticed, 1 volume of nitrogen will combine respectively with ½, 1, 1½, 2, and 2½ volumes of oxygen; or, what amounts to the same thing, 2 volumes of nitrogen will combine with 1, 2, 3, 4, and 5 volumes of oxygen.

As bodies thus combine with each other in definite proportions, it is obvious, that if we select any one substance as unity, or $=1$, all other substances may be represented by numbers equal to the weights in which they respectively combine with each other, and with the unit. Upon this principle of numeric representation, hydrogen, which is the lightest known substance, is assumed as unity; the compound of hydrogen with oxygen is water, in which 1 part by weight of hydrogen is combined with 8 of oxygen, to form 9 of water: hence, in a table of atomic numbers, definite proportionals, or chemical equivalents, (for all these terms have been applied to such numbers,) we have —

Hydrogen	represented by	1
Oxygen	. .	8
Water	. .	9

And in the above series of nitric compounds we have, in the first of them, 14 of nitrogen combined with 8 of oxygen; and, accordingly, calling 14 the equivalent of nitrogen, and 8 the equivalent of oxygen, we have the following equivalents of their compounds; and it may be presumed that these numbers represent the weights of the combining atoms of those bodies: —

Atoms *of nitrogen.*		*of oxygen.*	*Equivalents, or combining weights,* *of nitrogen.*		*of oxygen.*		*Equivalents of the compounds.*
1	+	1	14	+	8	=	22 nitrous oxide.
1	+	2	14	+	16	=	30 nitric oxide.
1	+	3	14	+	24	=	38 hyponitrous acid.
1	+	4	14	+	32	=	46 nitrous acid.
1	+	5	14	+	40	=	54 nitric acid.

This table also shows the nomenclature commonly applied to the compounds; the termination *ous* indicating the minimum of oxygen, the termination *ic* the maximum; the term oxide implying generally all those combinations of oxygen which are not sour, such being called acids. More frequently the relative proportions of oxygen in the oxides are designated by the first syllable of the Greek ordinal numerals: thus we have protoxides, deutoxides, tritoxides, &c.; and when the base is saturated with oxygen, the compound is termed a peroxide. When the same substance forms three or four acids, the term hypo is conveniently introduced with the termination *ous* or *ic*, as shown in the following table of the acids of sulphur: —

Atoms of *sulphur.*		*oxygen.*	*Equivalents of* *sulphur.*		*oxygen.*		*Equivalents of the acids.*
1	+	1	16	+	8	=	24 hyposulphurous.
1	+	2	16	+	16	=	32 sulphurous.
1	+	3	16	+	24	=	40 sulphuric.

There is also an acid of sulphur intermediate between sulphurous and sulphuric, composed of 1 atom of hyposulphurous acid and 1 of sulphurous acid; $(24+32=56)$ or of 2 atoms of sulphur and 3 of oxygen: this is appropriately called the hyposulphuric acid. The terms *sesqui* and *bi* are sometimes used to designate intermediate and double compounds of acids, or other bodies with bases: thus, we have three compounds of carbonic acid with ammonia, in which 1 proportional or atom of ammonia is respectively combined with 1, 1½, and 2 of carbonic acid, and these we call the carbonate, sesquicarbonate, and bicarbonate of ammonia. For a table of the equivalent numbers of the simple substances, *see* Equivalents.

Change of form and change of properties are the common consequences of chemical affinity. We observe, 1. Solids forming liquids (ice and salt). 2. Solids forming gases (explosion of gunpowder). 3. A solid and a liquid producing a solid (lime and water). 4. A solid and a liquid producing a liquid (all common cases of solution; as of salt and sugar in water). 5. Liquids producing solids (solution of carbonate of potassa mixed with muriate of lime). 6. Liquids producing gases (alcohol and nitric acid). 7. Gases producing solids (ammonia and muriatic acid). 8. Gases producing liquids (chlorine and olefiant gas).

The density of bodies is also materially affected by chemical combination; the density of a compound is very rarely the mean of its components, but generally increased: thus, almost all gaseous compounds occupy less bulk than their elementary gases in a separate state; there are, however, cases in which 1 volume of one gas, combined with 1 volume of another, produce exactly 2 volumes of a compound gas, the density of which is, of course, the mean of that of its components; and again, in the combinations of some of the metals with each other, and with sulphur, the density of the compound is below the mean of its elements. When certain liquids are mixed, great and immediate increase of density ensues, and much heat is evolved (sulphuric acid and water). Change of form and of density are often attended by remarkable changes in other qualities: thus, tasteless bodies produce active compounds (oil of vitriol is composed of oxygen, sulphur, and water), and active substances produce inert compounds (sulphuric acid and caustic potash produce the inert salt, sulphate of potash); so that it is utterly impossible, by any *à priori* reasoning, to determine what will be the consequence of chemical combination: useless elements produce useful compounds, and useless compounds yield useful elements.

Another important and curious consequence of chemical action is change of colour: the vegetable blues are generally reddened by acids, and rendered green by alcalis; the alcalis render many of the reds purple; and of the yellows, brown: chlorine destroys most colours; so does the joint action of light, air, and moisture (bleaching, &c.).

AFFI'RMATIVE. In Logic, denotes the quality of a proposition which asserts the agreement of the predicate with the subject.

AFFIRMATIVE QUANTITY. In Algebra, denotes a quantity to be added, in contradistinction to one to be taken away.

AFFIRMATIVE SIGN, or POSITIVE SIGN. The sign of addition, marked +, meaning plus, or more. Dr. Hutton observes, that the early writers on algebra used the word plus in Latin, or piu in Italian, for addition, and afterwards the initial *p* only as a contraction; like as they used minus or meno, or the initial *m* only, for subtraction; and thus their operations were denoted in Italy by Lucas de Burgo, Tartalea, and Cardan, while the signs + and — were employed much about the same time in Germany by Stifelius, Scheubelius, and others, to denote the same operations.

A'FFIX. In Grammar, a syllable attached to the end of a class of words, determining their meaning. Thus, a class of adverbs in English are determined by the affix *ly*; strongly, weakly, &c. Prefix is a syllable so attached at the beginning.

AFRA'NCESADOS. In Modern History, a denomination given in Spain to the party which attached itself to the cause of the French, or of the intrusive King Joseph, during the war of independence, 1808—1814.

AFT. *See* Abaft.

A'FTERMATH. In Agr. Grass which is mown, after the first crop of hay has been taken away, instead of being eaten off by stock.

A'GA. A title of dignity among the Turks and Persians, given to various officers: as, the aga of the janissaries, while that corps subsisted; the capi-aga, or chief eunuch of the seraglio, &c. It is also a common epithet of respect in addressing a distinguished person.

AGA'LMATOLI'TE. (Gr. ἀγαλμα, *image*, and λιθος, *a stone*.) The mineral which the Chinese carve into images.

AGA'MA. (Gr. ἀγαμαι, *I wonder at*.) The name of a lizard, employed by Cuvier to designate the

first section of the Iguanian sauria, or *Agamidæ;* which section is characterised by the absence of palatal teeth. The Agamoid lizards include several genera, which are numerous in species, and they are distributed over the warmer parts of America, Africa, Asia, and Australia. They have all the power of inflating the body, and of producing, but in a less degree than in the chamæleon, changes of colour, whence, probably, the origin of the name.

A'GAMOUS. (Gr. ἀ, *without*, and γαμος, *nuptials.*) A term substituted by some writers for cryptogamic, because such plants have in reality no organs analogous to sexes: it is, however, usually limited to such groups as confervæ, lichens, and fungi, because they have in reality nothing either analogous or similar to the sexes of more perfect plants; while, on the contrary, ferns and mosses, although they have not any real sexes, nevertheless are considered by some writers to possess parts of an analogous nature.

A'GAPÆ. (Gr. ἀγαπη, *love.*) Love feasts, in use among the primitive Christians. After the celebration of the communion, the oblations which had been made in the temple, consisting of meat and bread which the rich had brought from their houses, were consumed at a common feast. There is some dispute whether in the apostolic times this feast did not take place before the communion, in more exact accordance with the circumstances attending the institution of the sacrament. The agapæ or feasts in churches, were prohibited by the Council of Laodicea, A. D. 361, and the third of Carthage, A. D. 397.

A'GAPHITE. *See* TURQUOISE.

A'GARIC. (Agaria, *a kingdom in Sarmalia.*) A genus of fungi comprehending many hundred species, among which are, A. campestris, the common mushroom, and some others, which are delicate articles of food; A. muscarius and others that are dangerous poisons; many of the disgusting deliquescent fungi called toadstools; and numerous beautiful little ephemeral species, which appear to be harmless: A. olearius is remarkable for being phosphorescent. These plants uniformly grow in decaying animal or vegetable matter, among which their stem, or spawn, as it is commonly called, ramifies. After the spawn has arrived at the proper age, it ceases to branch, collects into parcels, and generates from those parcels the fructification, which forces its way into the light under the form of the agaric. The cap is the part where the spores or seeds for reproducing the species are generated; they are formed within the plates or gills that lie on the under side of the cap, and are little grey round bodies, which, when they are collected in great quantities upon a sheet of white paper, have the appearance of exceedingly fine dust. "Fairy rings" are caused by the underground stems of agarics which branch from a common centre, and only protrude their fructification at the circumference.

AGARIC MINERAL. A very soft mealy variety of carbonate of lime.

AGA'STRICS, AGASTRIA, AGASTRICA. (Gr. ἀ, *without*, γαστης, *a stomach; stomachless.*) A term which has been applied to certain animalcules, on the erroneous supposition that they were devoid of internal digestive cavities. (*See* POLYGASTRICS.) The term is still applied to a family of medusæ.

A'GATE. An aggregate of certain siliceous minerals, possessing hardness, and variety of colour and mixture, and admitting of a good polish. Chalcedony generally appears to be the base of agate; carnelian, jasper, amethyst, and other similar minerals, often enter into their composition.

A'GATHODÆ'MON. (Gr. ἀγαθος, *good*, and δαιμων.) A good spirit. (*See* DÆMON.)

AGA'VE. (Gr. ἀγαυος, *admirable.*) A genus of plants found in the temperate parts of America, resembling aloes in their mode of growth and general appearance, but differing in having an inferior ovary, and in their sensible properties. The best known species is Agave americana, called the American aloe, which has been naturalised on the coasts of the Mediterranean, where it assists, with Cactus opuntia, the palmetto, and date palms, to give a tropical air to European scenery. It is many years preparing the materials for its gigantic pyramid of flowers, and is so exhausted by the effort, that it quickly afterwards perishes. A sweet sap flows from its inward stem, and upon fermentation becomes an intoxicating beverage, yielding by distillation a powerful ardent spirit. Hemp of considerable strength is manufactured from its leaves. The genus agave is the type of one of the subdivisions of amaryllidaceous plants.

AGE. (Fr. *age.*) Means, generally, a definite period or length of time.

AGE. As applied to man, age may either mean the whole of his life, or a portion of it. It is usual to divide the whole period of human life into four parts or ages. The first, or infancy, extending to the fourteenth year; the next, or youth, from the fourteenth to about the twenty-fifth; manhood, from the twenty-fifth to the fiftieth or sixtieth; and the last, or old age, filling up the remainder. Ovid ingeniously compares these four ages to the four different seasons of the year. — (Metamorph. xv. ver. 200.) These divisions are, however, in a great degree arbitrary; and very frequently they have been extended to six, the first being divided into infancy and childhood, and the last into old age and extreme old age. Sometimes, also, the life of man is supposed to be divided into seven ages, the leading characteristics of which have been most admirably depicted by Shakespeare: —

> "His acts being seven ages. At first, the infant,
> Mewling and puking in the nurse's arms:
> And then, the whining schoolboy, with his satchel,
> And shining morning face, creeping like snail
> Unwillingly to school: And then the lover;
> Sighing like furnace, with a woeful ballad
> Made to his mistress' eyebrow: then a soldier,
> Full of strange oaths, and bearded like the pard,
> Jealous in honour, sudden and quick in quarrel,
> Seeking the bubble reputation
> Even in the cannon's mouth: and then, the justice;
> In fair round belly, with good capon lin'd,
> With eyes severe, and beard of formal cut,
> Full of wise saws and modern instances,
> And so he plays his part: The sixth age shifts
> Into the lean and slipper'd pantaloon;
> With spectacles on nose, and pouch on side;
> His youthful hose well sav'd, a world too wide
> For his shrunk shank; and his big manly voice,
> Turning again toward childish treble, pipes
> And whistles in his sound: Last scene of all,
> That ends this strange eventful history,
> Is second childishness, and mere oblivion;
> Sans teeth, sans eyes, sans taste, sans every thing."

For a scientific discussion of this subject, *see* MORTALITY.

AGE. In Law, is the period at which individuals are qualified to undertake certain duties and offices. By the common law of England, a man at fourteen is at the age of discretion, and may then appoint guardians, and marry with their consent: at twenty-one he is of full age, and may, consequently, exercise any civil privilege to which he may otherwise be entitled, that is, he may elect or be elected to parliament, be appointed a judge, alienate lands, &c. But no person can be admitted in England to deacon's orders till he be twenty-three years of age, nor to priest's till he be twenty-four. At twelve years a woman may marry, provided she have the consent of her parents or guardians; and at twenty-one she is her own mistress, and may dispose of herself and her estates.

Infants under seven years are held by the law of England to be incapable of committing felony. If persons above that age, and under fourteen, commit felony, they are *prima facie* entitled to an acquittal; but if it appear to the court and the jury that the accused was *doli capax*, or clearly understood the nature of the crime he was committing, they may proceed on the principle that *malitia supplet ætatem*, and subject the offender, as, in point of fact, has been repeatedly done, to the extremest penalty of the law. Persons above fourteen are treated in this respect as if they had arrived at full age. — (*Blackstone*, book iv. cap. 2.)

At Rome, the *consular age*, or the age at which a person became capable of holding the consular dignity, was fixed at forty-three, though in extraordinary cases this rule might be set aside. In France, at this moment, a man is not allowed to exercise the elective franchise till he be twenty-five years of age; nor to be elected a deputy till he be thirty. In some of the American states judges are obliged to retire when they have attained to a certain age, which is sometimes so early as sixty.

AGE. In Mythology, age means one or other of the four ages as described by the ancient poets. The first or golden age, *aurea ætas*, when there was an eternal spring, and when the earth spontaneously poured forth her harvests, and man

> —— "vindice nullo,
> Sponte suâ sine lege fidem rectumque colebat,"

was coeval with the reign of Saturn on earth. The next, or silver age, *argentea ætas*, was marked by the change of seasons, and the division and cultivation of lands. The third, or brazen age, *aenea ætas*, is described as

> "Sævior ingeniis, et ad horrida promptior arma:
> Nec scelerata tamen."

And then came the last, or iron age, *ferrea ætas*, full of all sorts of hardships and wickedness, which still continues. (*Ovidii Metamorph.*, i. lin. 89., &c.)

AGE. In Literature, age is a period distinguished by great improvements and eminence in arts and sciences, usually bearing the name of some powerful sovereign, or other prominent person, who flourished during that period. Of these ages, the most memorable are the age of Pericles, the Augustan age, the age of Leo X., the age of Louis XIV., &c.

AGE. In Chronology and History, age is sometimes used as synonymous with a century, and sometimes also with a generation. Writers differ in respect to the period included under what is called the *middle ages;* but they are commonly understood to begin with the reign of Constantine, and to extend to the fifteenth or the early part of the sixteenth century. The æra of the invention

of printing, 1450—1455, might, we think, be advantageously adopted as the termination of the middle ages.

AGE'NDA. (Lat. *things to be done.*) Small books are now published under this title, in which individuals may set down, under their proper heads, the things to be daily attended to.

AGENDA. In Divinity, articles of moral practice, in opposition to *credenda*, articles of faith. Also, the ritual of a church, and the books containing it.

A'GENT. In Law, is a person authorised to do some act or acts in the name of another, who is called his principal. An agent may, in general, be appointed by bare words, or his appointment will be inferred from circumstances; but, for some purposes specified by the statute of frauds, his appointment must be in writing. The agent of a corporation must, in general, be appointed by deed. If an agent has engaged to perform certain duties for a consideration, the performance may be enforced in law. But against an unremunerated agent, the principal can only recover damages for misconduct in the performance, and cannot compel him to proceed. With respect to the dealings of third parties with an agent, some general rules of law are, that the extent of an agent's authority is, as between his principal and third parties, to be measured by the extent of his usual employment; that the representation of an agent about the subject-matter of a contract which he is negotiating for his principal, will, if made during the course of the negotiation, bind the latter; that payment to an agent, in the course of his employment, is payment to the principal; that the principal is, under many circumstances, responsible in civil actions for the negligence or fraud of his agent, but not criminally liable for his acts, unless done under an express command.

AGENT. In Diplomacy, a general name, comprising several ranks:—as, 1. Ambassadors. 2. Envoys extraordinary and ministers plenipotentiary. 3. Ministers resident. 4. Chargés d'affaires. 5. Secretaries of legation, &c. In common language, however, the highest officer employed by one power at the court of another, is usually termed the agent of that power at the court in question. (*See* DIPLOMACY.)

A'GGREGATE ANIMALS. This term is applied to those animals which are collected together in a common enveloping organised substance containing numerous compartments, from each of which a distinct occupant sends forth a circle of organs to collect food, which, after assimilation, is carried by a common and continuous system of vessels for the support and enlargement of the common dwelling. Examples of animals so associated or aggregated occur in the class polypi, where they form most of the orders; also in the class acalephæ, forming the polytoma; and in the acephalous mollusca, forming the genera botryllus, pyrotoma, and polyclinum.

AGI'LIA. (Lat. agilis, *swift.*) A family of rodents in the system of Illiger, including the squirrels and dormice.

A'GIO. A mercantile term, denoting the percentage difference existing between the values of the current and standard moneys of any place. Also, the rate of premium which is given, when a person having a claim which can only be legally demanded in one metal, chooses to be paid in another. Thus, in countries where silver is the only legal standard, a large payment in silver is so inconvenient, that the receiver will often pay a small premium for the convenience of receiving gold: this premium constitutes the agio on gold.

A'GIOTAGE. A term employed to designate the sort of manœuvres by which speculators in the public funds contrive, by disseminating false rumours, or otherwise, to lower or enhance their price. It is sometimes also, though less commonly, applied to the machinations of those who endeavour, by similar artifices, to raise or depress the prices of commodities.

AGI'STMENT. In Law. From the old French word, *agister*, which signifies a licence granted for cattle, viz. to be harboured, or, in legal phrase, levant and couchant, on the land. A contract by which A.'s cattle are taken into B.'s ground, to remain there at a stipulated sum, paid periodically. Agistment is also used for the profits of such feeding. The "Tithe of Agistment," or of cattle and other produce of grass lands, demanded by the Irish clergy, was resisted, in 1720, by the landlords, and in effect abolished by a resolution of the Irish house of commons (1735). By the act of union, this resolution was passed into law; and thus the tithes of Ireland have, in effect, been thrown on the poorest part of the agricultural population, the owners and cultivators of arable land. (See *Ed. Rev.*, vol. xxxiv.: Wakefield's *Ireland*, vol. ii.)

A'GNATE. (Lat. agnatus.) In Roman Law, *agnates* are those who descend through males from a common ancestor; in opposition to *cognates*, i. e. all the descendants of a common ancestor, whether through males or females. Thus, in France, the hereditary crown passes by right of *agnation*, females being excluded.

AGNO'MEN. Besides the prænomen, nomen, and cognomen, the Romans sometimes had a fourth name (agnomen), which was derived from some illustrious action or remarkable event. Thus, two Scipios had the name Africanus given them, on account of their victories over the Carthaginians in Africa. The younger of these celebrated generals had a second agnomen, viz. Æmilianus, because he was the son of L. Paulus Æmilius, and adopted into the family of the Scipios.

A'GNON. A name applied by Fabricius to a genus of dragon-flies, having the wings erect when at rest, the eyes distinct, and the outer divisions of the lip bifid.

AGNO'STUS. (Gr. ἀγνωστος, *unknown.*) A name devised to express the obscure nature of a genus of trilobites (fossil crustaceans), to which it is attached; the genus is characterised by the semicircular or reniform shape of the body, which in all other trilobites is ovate or elliptical.

A'GNUS DEI. (Lat. *Lamb of God.*) 1. A prayer of the Roman Catholic church, which begins with the words, "Agnus Dei qui tollis peccata mundi." 2. An image of wax, impressed with the figure of the Lamb, consecrated by the pope, and distributed to the faithful.

AGO'MPHIANS, AGOMPHIA. (Gr. ἀ, *without*, and γομφιος, *a tooth.*) A term applied by Ehrenberg to those rotifers of which the jaws are deprived of teeth.

A'GONY. (Gr. ἀγωνια, *contest.*) In Divinity, the suffering of our Saviour in the garden on the night preceding his crucifixion. Luke, xxii. 24.

A'GORA. The market place of a Greek town, which was generally used also as the place where the assemblies of the people met. It answers to the Latin term forum. From the verb ἀγειρειν, *to collect*, or *assemble*. From agora is derived

AGORA'NOMUS. The title of an Athenian magistrate, forming one of a body of ten, or, as some say, fifteen, persons whose duty it was to superintend the markets, and collect the customs imposed on certain articles.

AGOU'TI. The Indian name of some South American herbivorous rodent quadrupeds, now included in the genus *Dasyprocta*.

AGRA'RIAN LAWS. (Lat. ager, *field.*) Under this term are comprehended the enactments which were carried or attempted to be carried at Rome by the plebeians and their partisans, in opposition to the patricians, touching the distribution made of the public lands accruing to the state by conquest. These were leased out to the patricians by the state at a moderate or nominal rent, while the plebeians gained nothing by them. The object of the agrarian laws, which did not interfere with private freehold property, was to obtain for the plebeians a share in these lands, to restrict the quantity occupied by individuals, and to cause a real rent to be paid from them for the support of the army. The most celebrated movers of these laws were, Sp. Cassius, Licinius, and the two Gracchi, whose reputation has suffered with posterity, from being intrusted to the hands of writers who favoured the party whose unjust encroachments were sought to be moderated by these laws. For a more impartial investigation of them than can be found in ancient writers, (for Cicero, from his aristocratic partisanship, has much misrepresented the objects of these reformers, and the character of the laws they sought to introduce,) see Niebuhr's *Roman History*. In consequence of the misrepresentations here alluded to, an "Agrarian law" now generally serves to denote a law for the spoliation of individuals, by reducing landed property in private hands to a fixed amount. The law of partibility of real estates, as it obtained in the Roman jurisprudence, and still more in countries where it cannot be controlled by testamentary disposition, has, in some measure, the effect of an Agrarian law, although free from its injustice.

AGREE'MENT. (Fr. agrément, *agreeableness.*) In the fine arts, a certain degree of resemblance between the parts, in style and character, so that they may seem to belong to each other.

AGREEMENT. In Law, that which is consented to by two or more parties. Agreements are divided into executed and executory. By the statute of frauds, 29 Car. 2. c. 3. no action can be brought to charge a defendant on any agreement upon consideration of marriage, or on any contract or sale of lands, &c., or any interest therein, or any agreement not to be performed within one year, unless such agreement or some memorandum or note of it be in writing, signed by the party to be charged therewith, or some other person by him thereunto lawfully authorised.

The remedy which law affords for the breach of an agreement is only by way of damages. But equity will in general compel the specific performance of any contract or agreement for the non-performance or breach of which a court of law could have awarded damages. The principal exception to this rule is, where the agreement is of such a nature that its breach can be or was intended to be compensated by damages.

A'GRICULTURE. (Lat. ager, *a field*, and colo, *I till.*) This art may be defined as that of cultivating land in fields, or in large quantities; as opposed to horticulture, which is the art of cultivating land in gardens, or in

small quantities: or, agriculture may be defined as the art of cultivating land with the plough; and horticulture that of cultivating it with the spade. The restricted meaning of the word agriculture, therefore, is simply the art of cultivating fields; but its more extensive and general meaning includes the whole business of the farmer, which comprehends, in addition to raising corn, and other crops, the management of live stock. As a general term, the word agriculture is also frequently considered as including every description of territorial improvement; thus it is made to comprehend embanking, road-making, draining, planting, and sometimes even horticulture. In this sense the word agriculture is used by the French writers on the subject.

We shall here consider the term agriculture in its general acceptation in Britain, and in other countries where the English language prevails, as only including the culture of field crops, and the rearing and managing of domestic animals, on a large scale; and we shall give a very concise outline of its origin, history, theory, and practice.

The origin of Agriculture must doubtless have been coeval with that of fixed property. In the pri-næval state of society, the sole riches of the husbandman consisted of flocks and herds, which were kept in a state of movement from one point to another, in search of pasturage and water; but as population increased, mankind adopted a fixed abode; this could only be done by bestowing on the site a certain degree of labour and care, which became, as it were, the price paid for constituting it private property. At this point in the progress of civilisation agriculture may be said to have commenced. Previously, the natural products of the soil were merely consumed where they were found; but now man sought to increase them by culture.

History of Agriculture.—The culture of the land will be found to have depended, in every country, principally on its climate, and its civilisation; though partly, also, on its government and population. In the warmer climates, where nature produces fruits in the greatest abundance for the food both of men and animals, and where very little care is required to procure shelter or clothing, agriculture has made little progress; because it is comparatively unnecessary for the prosperity of the inhabitants. In climates of a directly opposite character, agriculture has made equally slight progress, from the natural obstacles opposed to it. In such countries, for example, as Greenland and Kamschatka, only one or two kinds of corn crops can be cultivated, and perennial grasses can scarcely exist; because the ground is covered with snow for eight months in the year: and in these countries agriculture is but little practised, as the chief resources of the inhabitants for food are found in the sea and the forest. In intermediate climates, such as those of the south of Britain, the middle of France, and the north of Italy, the soil may be laboured by man throughout the whole year; and there is scarcely any limit to the kind of crops that may be raised on it. In such climates, agriculture is calculated to attain the highest degree of perfection; and comparing the different parts of the zones of this description of climate in both hemispheres, perhaps it may be asserted, that the best agriculture in the world is to be found in Britain and in the north of Italy; viz. in East Lothian and Norfolk, in the vale of Arno, and on the banks of the Po. The kind of agriculture practised in different countries is also of course adapted to the difference of climate. Thus, towards the north, the great art of the cultivator would consist in supplying heat; or, rather, in adopting such measures as would best guard plants and animals against cold, rains, and the vicissitudes of the weather. Towards the south, on the other hand, the art of the cultivator would be chiefly directed to moderating extreme heat, and supplying moisture. It thus appears that the agriculture of any country necessarily depends on its latitude; and that in high and low latitudes, where there are greater extremes of temperature and climate to contend with, agriculture must be of a more difficult and hazardous description than in intermediate or temperate climates: such as that of Syria, where the art is supposed to have originated, or in Europe, where it may be considered as having attained its highest degree of perfection.

In tracing the progress of this art in civilised countries, we have only to follow the chronology of general history. As the Greeks and Romans appear to have arrived at as great a degree of perfection in legislation as the moderns, so they appear to have attained nearly equal excellence in the practice of agriculture. Till within the present century, very little difference existed between the most approved agriculture of climates analogous to that of Italy, and the agriculture of the Romans as described by Cato, Columella, and other ancient writers. The chief superiority of the moderns consists in their machinery, and in their knowledge of the science of the art; the last being of very recent date, and by no means general among practitioners. By science, improved breeds, both of plants and animals, have been originated; and by improved machinery, a more perfect tillage has been produced, and also a more complete separation of the produce from the soil, from the refuse of the plants which bore it, and from all impurities.

The history of agriculture in Britain begins with that of the Roman conquest. Julius Cæsar found the inhabitants in a state of semi-barbarism; but Agricola left them in possession of all the arts of civilisation then known. Agriculture declined with the invasion of the Saxons; but was preserved through the dark ages after the establishment of Christianity, by the intelligence of the religious establishments, who gradually became possessed of the greater part of the landed property of the country. Agriculture revived in the reign of Henry VIII., and in that of Elizabeth, during the long period of peace which then prevailed, and the consequent security of property; and it afterwards declined during the civil wars: it again revived during the reigns of William and Mary, Queen Anne, and George I., in consequence of the introduction of the Flemish husbandry, which included the culture of turnips and clover. A still greater stimulus to the art was given during the reign of George III. by the introduction of ploughs drawn by two horses, instead of four or six; of the drill system, and its application to the culture of turnips and potatoes; and by the improvement made in the breeding and rearing of live stock by Bakewell and Culley. Early in the present century, the threshing machine was an important addition to agricultural machinery; the reaping machine, the frequent drain system, and the subsoil plough, are improvements just coming into use; and the next grand attempt will probably be the general application of steam, instead of horses or cattle, in tillage and other field operations.

The literature of agriculture commences with the works of the Romans, of which Columella's work, "*De Re rustica*," may be considered the most comprehensive. In the dawn of modern agriculture, the principal writers were, Crescentius in Italy, Herrera in Spain, Olivier de Serres in France, Hereshbachius in Germany, and Fitzherbert in England. At the beginning of the present century the most comprehensive author on agriculture in Italy, was Filippo Re; in France, Tessier; in Germany, Thayer; and in England, Marshall. The best work from which a general idea may be obtained of the agriculture of France and corresponding climates, is "*Maison Rustique du xix^e siècle; ou, Encyclopédie d'Agriculture pratique*," complete in one thick volume, 8vo.; and the corresponding work in Britain is Loudon's "*Encyclopedia of Agriculture.*"

The principles of Agriculture are derived from a knowledge of the nature of plants and of animals, of soils and manures; and of the climate, the seasons, and the weather. Plants are organised beings, which take up their food, by means of roots, from the interior of the soil; animals are organised beings which select their food from vegetables growing on the surface of the soil, or from other animals, and this food is prepared before being absorbed into the system, by means of a stomach. The climate of a country determines both the plants and the animals which can be produced in it; and the seasons and the weather, the time when the plants and animals of the given climate are in particular states of vigour or torpidity; and when certain operations of culture can be performed on them, or on the soil.

The nature of these elementary materials being understood, even though imperfectly, certain improvements can be effected in them by art, which are greatly conducive to the increase of agricultural produce. The kinds of plants and animals suitable to any given climate, soil, or season, are determined by the laws of nature; but from among these kinds it is in the power of man to make a selection; and with the plants and animals so selected to originate others, adapted to his purposes in a superior degree. Hence the importance of selecting certain breeds of animals rather than others; and of making choice, not merely of one kind of bread-corn rather than another, but of particular varieties of that corn. Thus, in the case of wheat, there are some kinds the grains of which, under no circumstances, weigh more than from 50 to 55 pounds a bushel; while there are others which never weigh less than 60 pounds a bushel. The nourishment of plants has been found to depend chiefly on organised matters contained in the soil, and produced chiefly by the decay of other plants. This is a law of nature, which, followed up by man, has led to the use of manures; as the fact, every where observed, that no plant can live without water, has led to irrigation; and, as the observation that the excess of water is injurious, has led to surface and under draining. The influence of temperature and shelter over the growth of plants, and the thriving of animals, is every where observable in wild nature; and though the temperature of a climate cannot be changed, yet that of most localities may be improved by shelter from cold winds, and by diminishing the evaporation from the surface, by means of surface and under draining, to draw off the superfluous water. The most important principles in the theory of agriculture are those which relate

to the improvement of plants and animals, and of the soil.

The improvement of the soil may be comprised under two heads — the improvement of its earthy part, and the increase of the organised matter added to the earths. The improvement of the soil, considered as a mixture of different earths, consists in rendering it more or less retentive of water, by diminishing or increasing the size of the particles of which it is composed : for example, by the addition of clay in some cases, and sand in others ; and by improving the earthy composition of the soil by the addition of such earths as may be in too small quantities, or wanting altogether. It has been found, from experience, that those soils which are composed of several primitive earths are naturally more productive than such as consist of only one earth, all other circumstances being the same ; and it has also been found that no soil will maintain its fertility for any length of time that does not contain a certain portion of calcareous earth in its composition. Hence one of the most common means of improving all soils not calcareous is, by the addition of lime ; and of all other soils, by mixing them with such as are of an opposite description.

All soils whatever are rendered more productive by the addition of organised matter, or what are called manures. Manures may either be composed of animal or of vegetable matter ; and these may either be applied separately or together, and in a fresh state, or in a state of decay. It has been found from experience, and explained by chemical experiments, that every description of manure is rendered more effective by being made to undergo putrefactive fermentation before it is applied ; and this process is carried on with solid manure in heaps or dunghills, and with liquid manure in tanks or wells. In the application of manure to soils, the great object of the cultivator is to apply enough for the ensuing crop, and as little more as possible ; because all that is applied and not immediately used, is liable, to a certain extent, to have its particles carried off by evaporation into the atmosphere, or by rains into rivers or the sea. But, even if this were not the case, to apply manure to a soil where it would not be immediately turned into a crop, would be an expenditure of capital without interest.

The operation of freeing a soil from superfluous water is of equal or perhaps more importance than supplying it with manure ; because, though without manure plants will not grow with great luxuriance and vigour, yet with too much water they will not grow at all, or will become sickly. The excess of water may proceed from three causes : an extremely moist climate, the only alleviation to which is arranging the surface with frequent furrows, and short slopes between them, so as to carry off the rain as soon as it falls ; a soil very retentive of moisture, so as to hold it like a sponge, in which frequent under drains, as near together as the surface furrows, are required ; and, lastly, a soil lying over a subsoil which abounds in springs, or, in other words, which has the substrata charged with water, which is continually oozing out through the surface soil. The remedy for this last evil is by under drains of considerable depth, so directed as to collect the water from the substrata, and carry it off before allowing it to reach the surface soil.

A soil, after being drained and rendered of a proper texture and composition by the admixture of such earthy ingredients as may be wanting, requires, to render it fit for being penetrated by the roots of plants, to be frequently stirred and comminuted. This is done by the mechanical operations of ploughing, harrowing, &c. ; which, aided by the alternate action of droughts and rains, frosts and thaws, and summer and winter, have the effect of pulverizing the soil. To maintain a soil in a fertile state, it is not only necessary to supply it with manure in proportion to the crops which have been carried from it, but to vary the crops which it is made to produce. It has been found from experience that crops of plants belonging to the same natural family do not succeed so well after each other, as when crops of a different family are made to intervene. Thus, the several grasses alternate better with root or herbage crops than with one another ; or, one of those grasses of which the seed is ripened will alternate better with another in which the herbage only constitutes the crop, than with one of the same kind as itself. Something analogous to the succession of crops takes place also with regard to the pasturage of animals, and it is found advantageous to put cattle in a field that has been grazed by horses, rather than to put horses after horses, and cattle after cattle.

Thus, the principles of agriculture may be comprised under the selection of breeds of plants and animals ; the improvement of the soil and subsoil ; the culture or movement of the soil ; the improvement of the local climate by shelter and drying ; and the succession of crops. All these principles have been derived from experience ; and they are only in part accounted for by chemistry or natural philosophy. They are not, however, on that account, the less true and useful. It is singular that they should all have been known to the Romans, and, to all appearance, as fully so as they are to modern cultivators.

The practice of Agriculture in Britain may be included under the heads of the choice, hiring, and stocking of a farm ; and its general culture and management. In the choice of a farm in any given country, the object of greatest importance is the nature of the soil ; because, though this may be improved by art and expense to such a degree as almost to render a bad soil equal to a good one, yet in practice this would be so expensive as by no means to answer the purpose of the farmer. It may be thought that the vicinity of good roads, of a canal, a river, or a market-town, are objects of more importance than the nature of the soil ; but this is not the case, because, supposing the roads to be bad, and the market at a distance, it is only necessary to change the system of cultivation and management, and to turn the produce of the farm into some description of live stock which may be driven to any distance, even over a country without roads. If it be alleged that the nature of the climate is of paramount importance to the soil in the choice of a farm, we allow that in an extended sense it is ; for example, if a cultivator had the choice of any part of Europe, there are doubtless many districts where the climate is far more favourable for all the operations and products of agriculture than others ; and even if he had the choice of every part of Britain, he might find some localities much more favourable than others. In general, however, the actual choice of any cultivator lies within a given locality, where the climate, in a practical point of view, is every where the same. Next to soil and climate in the choice of a farm, the state of the buildings and fences on it, the state of the roads, and the distance from a market-town, a canal, or a sea-port, are of importance. Without buildings of a sufficient extent, properly situated, and of the proper kinds, the business of a farm cannot be carried on ; and though some farms, and some kinds of farming, may be conducted without fences, yet, in general, fences are as necessary as roads. The last circumstance which we shall mention in this cursory glance is, the nature of the tenure by which the farm is to be held, and the covenants and conditions of the lease. No cultivator, who calculates on the employment of a considerable capital, will risk it on the lands of another without some security for having it returned ; and this security is a lease for a fixed number of years. On the other hand, no proprietor of lands will delegate the possession of them to another for a fixed number of years, without a valuable consideration ; and this he reserves to himself in the lease, under the denomination of rent. As lands in a state of cultivation, and buildings and fences in a state of repair, are liable to be injured and deteriorated in value by bad management or neglect, the proprietor guards against these accidents by certain conditions in the lease.

The kind of culture and management adopted in any farm depends jointly on the soil and climate ; and on the kind of produce most in demand, or reckoned most profitable. In the mountainous districts of Great Britain, where the climate is cold, almost the only kind of farming practised is that of breeding and rearing different kinds of live stock ; such as sheep or cattle, which are sold for being fattened in more favourable districts ; or horses, in order to supply the demand for these animals for the purposes of draught, or the saddle. The mountainous districts of Scotland and Wales are chiefly devoted to the breeding and rearing of sheep and black cattle ; which are sold to the farmers of the low country in both kingdoms, in order to be fattened for the shambles. The hilly districts of Yorkshire and Lancashire are chiefly employed in the breeding and rearing of horses. In the low country of the east coast of Great Britain, the climate being dry, is favourable for the culture of corn ; while on the west coast, and in Ireland generally, the climate being moist, is more favourable for pasture. The farm products most universally in demand are, corn and butcher's meat ; and these may be produced on every farm the fields of which admit of being kept alternately in tillage and in grass. The butcher's meat may, however, be produced in much greater abundance, on such soils as admit of the culture of root and herbage crops, such as turnips, potatoes, clover, &c. ; while corn may be produced most abundantly in strong loamy soils, within reach of extensive sources of manure. The most profitable description of crop will frequently be found to be different from that which is most generally in demand : for example, in the neighbourhood of a large town, the culture of culinary vegetables, on a large scale, in what are called farm-gardens, is generally far more profitable than the raising of corn or butcher's meat. Even the raising of food for cattle, in such situations, is found to yield more profit than common farming. There are also particular crops which may be occasionally cultivated which yield extraordinary profits ; such as plants used in dying, or in some manufacture not common ; plants of some new and improved variety of the kinds in general cultivation for their seed, &c.

A farm being fixed on, all preliminary matters settled,

and the farmer in possession, his first business will be to fix on the general system of cultivation that he means to adopt. In this, as already observed, he will be guided by what the farm is capable of producing, and what he can dispose of. One of the first points that he will determine after this, will be the quantity of land that he can have under each particular kind of crop that he intends to grow; and next, the order in which these crops are to succeed one another. No point, indeed, in the whole system of farm management, is of more importance than the succession, or, as it is usually called, the rotation, of crops. The principle on which the succession of crops is founded has been already hinted at; and in here treating it practically, it may be sufficient to state, that all agricultural crops whatever may be reduced to three kinds — exhausting crops, restoring crops, and cleaning crops; and that the perfection of a rotation consists in always having an exhausting crop followed by a restoring or a cleaning crop; or, what is best, by both combined. All crops which are allowed to ripen their seeds, or which are carried wholly off the ground, are considered exhausting, though in different degrees. Thus, the most exhausting crops in general cultivation are those of corn; but clover, tares, or even hay cut green, are also exhausting, though in a much less degree. Restoring crops are those where the produce is suffered to decay on the ground, or is consumed on it; as in the case of pasture, crops of tares, turnips, &c. Cleaning crops are such as are grown in drills, sufficiently wide to admit of hoeing and other operations of cleaning between. Some of these are at once cleaning and exhausting, as where corn is sown in drills; while others are cleaning and restorative, such as where herbage plants, as clover and lucerne, or roots, as turnips, are drilled, and the plants are to be eaten off on the spot. Other principles which enter into consideration in fixing on a rotation of crops are, that plants which are nearly allied should not succeed each other; because, whether from exhausting the soil of one particular kind of nutriment, or by depositing in it one injurious kind of secretion, certain it is, that the same kind of plants cultivated without intermission on the same soil soon become sickly. Thus three or four crops of any kind of corn in succession will not only unfit the soil for that variety or species of corn, but in a great measure for every other.

The farmer having determined on the crops which he is to grow, and the order of their succession, his next business is to calculate the quantity of stocking which will be required for his farm. By stocking is to be understood the number of horses, cattle, and other live stock; and the kind and number of machines, implements, and tools that will be required. In addition to these, he must take into calculation the number of male and female servants which it will be necessary for him to keep, either permanently by the year, or to hire occasionally by the week. Lastly, he will have to take into consideration the sum of money which he will require to lay out for servants' wages, housekeeping, rent, and all other expenses, before he receives any return from his farm produce. The sum total is the amount required for what is called stocking a farm; and it amounts, in different parts of the country, to from 5*l.* to 10*l.* per acre. Poor soil under pasture requires the smallest sum per acre; and rich soil under tillage the largest sum.

The farm being entered on, and the system of culture determined, the future business during the lease is one uniform routine of preparing, sowing, reaping, threshing, and marketing; including, where the breeding or fattening of live stock enters into the system, their purchase, fattening, and sale; or, their rearing, breeding, and sale.

The agriculture of Britain, and especially of the low country of Scotland, excels that of most other countries having similar climates, from the superior skill, intelligence, and capital of the farmer; the considerable length of lease which is granted by the landlord; the superiority of the machines and implements employed; and the improved breeds of animals and plants which are reared or cultivated. Perhaps the nearest approach to perfection in the culture of arable land in any part of Britain, is made in some parts of East Lothian; where, in consequence of deep ploughing, substituting under drains for furrows; regularly supplying manure, and alternating cleaning and restoring crops with exhausting crops, as great an amount of produce is obtained as can stand on the surface at one time. The agriculture of Britain is most defective in the southern districts of the island; in consequence of the farmers being the very opposite of those in the northern districts, the want or the shortness of leases, and the restrictive clauses in those leases, by which the tenant is prevented from exercising his own judgment, and is obliged to follow in the routine prescribed in the leases of a former age.

A'GRIMONY. A wild plant with sawed pinnated leaves, and a long spike of yellow flowers, followed by burlike fruit. It has had the reputation of keeping old age away from those ladies who persevere in the use of it in decoction. At least, it has the merit of being harmless, and from its slightly tonic qualities it would probably form a good kind of diet drink.

AGRIO'NIDÆ. (Gr. ἀγϱος, *a field.*) The name of a family of neuropterous insects, including the various kinds of dragon-flies (*Libellula*, Linn.; *see* that word). The blue dragon-fly (*Agrion puella*) frequents the rushy sides of ditches, and is one of the commonest of the British species of this family.

AGRO'NOMY. (Gr. ἀγϱος, *a field*, and νομος, *a rule.*) The art of cultivating the ground: sometimes used, particularly by the French, as synonymous with agriculture.

AGROSTO'LOGY. (Gr. ἀγϱωστις, *a grass*, and λογος, *a speech or writing.*) That part of botany which comprehends what relates to the grasses.

AGRY'PNIA. (Gr. ἀγϱυπνος, *sleepless.*) Watchfulness or restlessness.

A'GUE. An intermittent fever, which comes on at certain intervals, leaving the person in the intermediate periods in apparent health. The febrile attacks are often remarkably regular, whence the division of agues into quotidians, which are daily attacks; tertians, which appear every third day, having an intermission of forty-eight hours; and quartans, the intermission of which is about every seventy-two hours. The period during which the fever continues is called the paroxysm or pyrexial period; and the intermission, the apyrexial period. The febrile paroxysm consists of three stages, which follow each other in regular succession; namely, the cold, the hot, and the sweating stage: during the latter, the febrile symptoms abate and disappear.

AGUE CAKE. An enlargement of the liver or of the spleen produced by the ague.

AGY'RATE. (Gr. ἀ, *without*, and γυϱος, *a circle.*) A name given to osmundaceous plants by Swartz, in consequence of their having no true elastic annulus.

A'HRIMAN, or ARIMANIUS. (East. theology.) One of the chief deities of the ancient Persians. Their philosophers entertained the opinion subsequently held by the Manicheans, that there were two principles, one of good and one of evil. To the latter they gave the name of Ahriman, and ascribed to his agency all the evils existing in the world. The two principles were not, however, supposed to be co-eternal or alike powerful, at least such was not the orthodox belief; but it was supposed that in the end, the principle of good, Oromasdes, would finally prevail over and utterly destroy the principle of evil. — (*Bayle*, arts. ARIMAN, MANICHE'ENS, and ZOROASTER.)

AI. A word which is a pretty close imitation of the plaintive cry of the three-toed sloth (*Acheus tridactylus*, F. Cuv.). of which it is the trivial name. *See* BRADYPODÆ.

AID. A pecuniary tribute paid by feudal vassals to their lords in certain cases of emergency. (*See* FEUDAL SYSTEM.)

AIDE-DE-CAMP. An officer appointed to attend a general officer in the field, in winter-quarters, and in garrison, to receive and carry orders. A field-marshal is entitled to four, a lieutenant-general to two, and a major-general to one. The king appoints as many as he pleases, and this situation gives the rank of colonel.

AIGRETTE, in Botany. *See* PAPPUS.

AIR, *Atmospheric.* (Gr. ἀηϱ, *air.*) The air which surrounds our globe to a height of about forty miles, and which is essential to all living beings, was one of the elements of the ancient philosophers: its weight and several of its mechanical properties were discovered by Galileo and Torricelli about the middle of the seventeenth century; but its composition was not accurately determined till more than a century afterwards.

The air is transparent, colourless, inodorous, and tasteless, essential to the respiration of animals and vegetables, and to the support of combustion. It is 816 times lighter than its bulk of water; 1000 cubic inches, at mean temperature and pressure, weighing about 305 grains.

The air is a mixture of nitrogen and oxygen gases, with a small portion of carbonic acid gas and of the vapour of water: in particular situations, other substances exist in it; as, over marshes, miasmata; over sulphureous springs, sulphuretted hydrogen; over and near the sea, in dry weather, muriatic acid, either free or combined; and a substance, probably of organic origin, which, aided by light, reddens solution of silver; peculiar organic combinations, sometimes infectious, where people, especially the sick, are confined; sulphurous acid and ammonia, in London and other places where large quantities of coal are burned; and traces of nitric acid during severe thunder-storms.

The leading constituents of the air are nitrogen and oxygen, which are to each other in the relative bulks of about 79 and 21, or 80 and 20; and these proportions are probably not liable to any appreciable change, either dependent on season, wind, weather, situation, or height from the surface. Berthollet found 21 per cent. of oxygen in Cairo and in Paris; Saussure, the same in Geneva; De Martyr, in Catalonia, and in all winds, weather, seasons, and states of the barometer; in wet and dry, and in

inhabited and uninhabited places; Davy, in Bristol and other places in England and upon the coast; also in air brought from the coast of Guinea; Brande, in air from Behring's Straits and from Otaheite: Berger, in the Jura, and in the mountains and valleys of Savoy: Configliachi, on the Simplon and Mont Cenis (20·8 of oxygen over rice-fields); Gay Lussac and Humboldt, in Paris, and in all seasons and weathers, and at 6,636 mètres above the surface, from 20·9 to 21·5.; Dalton, in England, from 20·7 to 20·8.: Selden, 21.: on the 8th of January, 1835, the barometer being 30·9 inches and a north-east wind, 21·15. In crowded and confined places, the relative proportion of oxygen may be a little below the proper standard, but is soon again restored. Air collected at the back of the upper gallery in Covent Garden Theatre, on a full night, gave 20 oxygen, and rendered lime-water more than usually turbid.

The relative proportion of carbonic acid is more variable; yet this gas is found in air from the most elevated regions and purest sources. Saussure and Beauvais found it on the top of Mont Blanc, and in the same proportion in the streets of Paris, and at 650 toises above the city. At sea, carbonic acid has sometimes not been discoverable. Saussure found it vary with the seasons, and no doubt vegetation may affect it. In August, over a meadow, the air contained 0·000,713, in January, 0·000,425. Dalton estimates the mean proportion of carbonic acid at 1 in 1000; Configliachi, the maximum at 8, and Humboldt at from 5 to 18: this is probably in excess.

The aqueous vapour is the most variable constituent of the atmosphere. It is more abundant with a south and west wind in summer and in warm weather, than with a north and east wind in winter and cold weather. In this climate it usually fluctuates between 1 and 1·5 per cent.

Dr. Prout, in his Bridgewater Treatise (p. 350.), has suggested the possibility of the occasional existence of extremely minute portions of foreign and poisonous matters in the air during the prevalence of epidemic disorders; and, in reference to this subject, a remarkable observation occurred during the prevalence of the cholera. For more than six weeks previous to the appearance of cholera in London, he had been almost every day engaged in accurately determining the weight of a given quantity of air under precisely the same circumstances of temperature and pressure. On the 9th of February, 1832, the weight of the air suddenly rose above the usual standard, and it continued so for six weeks. On the 9th of February, the wind, which had been west, veered round to the east, and the first cases of epidemic cholera made their appearance.

Without reference to the occasional presence of foreign matters, the average ordinary constitution of the atmosphere may be stated as follows:—

	By measure.	*By weight.*
Nitrogen	77·50	75·55
Oxygen	21·00	23·32
Aqueous vapour	1·42	1·03
Carbonic acid	0·08	0·10
	100·00	100·00

Air. In Music, signifies the *melody*, or treble part of a musical composition.

The word is also used for a tune, or song itself, that is, for a series of sounds whose movement is regular and graceful.

Air. In Painting, the medium in nature through which every object is viewed, and hence to be transferred to the imitation on canvass. The effects which it produces are an indispensable part of the knowledge of every artist. It affects the sizes and colour of objects according to their distance.

AIR-BLADDER, called also *Air-bag*, sound, swim, &c. An organ situated in the abdomen of most osseous fishes, which, by altering its dimensions, and the quantity or density of its contents, regulates their relative position to the surface of the water, and is supposed to represent the rudimental condition of the lungs of the higher vertebrates.

AIR-CELLS. Are cavities in the stems and leaves of plants, constructed of cellular tissue, and intended to render the part in which they reside buoyant in water.

Air-Cells. In birds, are membranous receptacles communicating with the lungs, eight of which, of large size, occupy the interspaces of the thoracic and abdominal viscera; the smaller ones extend around the principal joints of the four extremities, penetrate the substance of the bones, insinuate themselves between the skin and subjacent muscles, and enter the quills of the feathers, so that the whole body of the bird is permeated by the atmosphere; whereby its specific gravity is diminished, its respiration extended, its circulation accelerated, and its muscular energies increased, and thus it is finally adapted to wing its way through aërial space. In the flying insects the air-vessels are more or less dilated into air-cells at different parts of their course, in order to diminish the specific gravity of the general mass of the body.

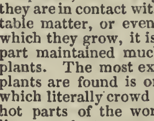
AIR-GUN. An instrument for projecting bullets or other missiles, the moving power being the elastic force of condensed air. A strong vessel of metal is constructed, into which air is forced by means of a condensing syringe, through a small hole with a valve opening inwards, and the greater the quantity of air thrown into the vessel, the greater will be the effect, the elastic force of air being nearly in proportion to its condensation. The magazine of condensed air is then detached from the syringe, and screwed to the breech of the barrel; and a trigger, adapted to the stock of the gun in the usual way, is constructed so as to be capable of opening the valve. The bullet is placed near the breech, and should fit the barrel very exactly, so as to leave no windage. On pulling the trigger the condensed air escapes through the valve, and rushes with violence into the barrel, propelling the bullet before it; and the instant the finger is withdrawn from the trigger the valve is closed by the pressure of the air in the magazine, which remains in a somewhat less condensed state for the next discharge. Thus the same supply of air in the magazine will serve for several successive discharges, but the force becomes weaker and weaker after each.

The air vessel may be of any form, but it is most conveniently disposed of by placing it within the stock; and this circumstance usually determines its shape and dimensions. Sometimes, also, a reservoir of bullets is placed in a channel under the barrel; and by a simple mechanism these are successively transferred into the barrel, whereby the gun is quickly loaded after each discharge. The instrument thus constructed is called the magazine air-gun.

The elastic force of inflamed gunpowder is from 1000 to 2000 times greater than that of common air. It would seem, therefore, that air would require to be condensed upwards of 1000 times beyond its natural state, in order to exert the same propulsive force as gunpowder. Now the velocities communicated are as the square roots of the forces; therefore, if the air in the magazine be condensed only ten times, it consequently exerts a force only equal to 1-100th of that of inflamed gun-powder, and communicates a velocity of 1-10th. There is a circumstance, however, which adds considerably to the effect of the air-gun, namely, that as the magazine is large in proportion to the cavity of the barrel, and the valve remains open a sensible portion of time, the ball is urged all the way through the barrel with nearly the same force as at the first instant; whereas, in the case of gunpowder, the gas produced by the inflammation occupies a small space in proportion to the capacity of the barrel, and the force ceases to act before the ball has quitted the barrel. On this account it happens that air condensed only ten times in a magazine of considerable size, projects a ball with a velocity not greatly inferior to that given by gunpowder. The time and labour necessary for effecting the condensation of the air prevents the instrument from being employed as an engine of war; but, as it produces its effect with less noise than the ordinary gun, it has sometimes been made subservient to the purpose of the assassin.

AIR-PLANTS. A name given to plants of any kind which grow without their roots penetrating the earth. They have been so called, from its being supposed that they derive their nourishment exclusively from the atmosphere; but as they are usually found in places where they are in contact with at least minute quantities of vegetable matter, or even with the juices of the plants upon which they grow, it is probable that their existence is in part maintained much in the same way as that of other plants. The most extensive natural order in which air-plants are found is orchidaceæ, thousands of species of which literally crowd the forests of some of the damp and hot parts of the world. Next to these range bromeliaceous plants, some of which will live for months suspended freely in the air, or tied to iron or stone balconies. Various species of ficus, and some Gesneraceæ, have similar habits. The only real air-plant that grows wild in Great Britain is cuscuta.

AIR-PUMP. A pneumatic machine for removing the air out of a vessel. The principle of this important philosophical instrument is very simple, and may be easily comprehended from a brief explanation. The essential



part of the machine consists of an exhausting syringe (a), formed of a tube or barrel of brass, closed at one end with the exception of a small orifice, to which a valve (b), opening inwards, is attached. An air-tight piston is worked up and down in the barrel by a rack and pinion turned by a winch. The piston has also an orifice with a valve (c) which opens upwards, or in the same direction as the valve of the tube. The syringe communicates, by means of a small pipe (d) fitted into the opening at its lower extremity, with a vessel (e) called the receiver, from which the air is to be extracted.

The receiver is placed on a brass plate (f, g,) over a

small hole, into which the other end of the pipe is inserted; and in order that the contact may be air-tight, the edge of the glass is previously rubbed with lard or some unctuous matter.

Suppose the piston at the bottom of the tube. As it begins to be drawn up, the valve *c* of the piston is immediately shut by the pressure of the exterior atmosphere, so that no air can enter the barrel, and a perfect vacuum would be left under it, were it not that the valve at the bottom of the barrel is forced open by the pressure of the air in the receiver, which rushes into the barrel till its density becomes the same both in the receiver and barrel. When the piston has been drawn to the top of the barrel, the whole of the air which occupied the barrel has been removed, and the receiver and barrel are now both filled with the air which was previously contained in the receiver alone.

Suppose the capacity of the receiver to be six times that of the barrel, the air which at first occupied six measures now occupies seven, and is consequently reduced to 6-7ths of its former density. Let the piston now be returned to its first position. The instant it begins to descend, the valve *b* shuts, so that no air can enter the receiver. As soon as the piston has descended through one-seventh of the barrel, the air in the barrel is restored to the density of the exterior atmosphere; and as it descends further, the air in the interior of the barrel is condensed, till it acquires an elasticity sufficient to open the valve *c* in the piston, when it rushes out, and continues to do so till the piston has quite returned to the bottom of the barrel. Thus by one stroke of the piston the density of the air in the interior of the receiver is reduced to 6-7ths of its previous density; and it is evident that each succeeding stroke will produce the same effect, or remove 1-7th part of the remaining air. Consequently, after the second stroke, the density of the air in the vessel will be reduced to 6-7ths of 6-7ths = 36-49ths of the exterior air; after the third stroke it will be reduced to 6-7ths of 36-49ths = 216-343ds, and so on. After twenty-one strokes, it will be reduced to about 1-25th of its first density; after one hundred strokes, to 1-5,000,000th part. But so high a degree of rarefaction cannot in practice be obtained; for as soon as the elasticity of the air in the receiver is reduced so far that it has not sufficient force to lift the valves, no more air can escape from the receiver into the tube, and the exhaustion cannot be carried further.

What has now been said applies to all air-pumps, though the form of construction admits of great variety. The better sorts have two exhausting barrels, and the pistons are worked by a rack and pinion, so that when the one piston is ascending in the barrel, the other is descending, by which means an uninterrupted discharge of the air is kept up. The receiver is placed on a smooth plate of brass, having a small hole in the middle to receive the end of a pipe communicating with the syringe. Various contrivances have been employed to continue the exhaustion after the air has been rarefied to that degree that it does not retain sufficient elasticity to lift the valves. In order to determine the degree to which the rarefaction is carried, a barometric tube is adapted to the machine, the upper end of which communicates with the receiver, while the lower end is plunged into an open basin of quicksilver. As the receiver is exhausted, the air is withdrawn from the tube at the same time, and the external air presses up the mercury in the tube to a height proportional to the degree of rarefaction.

This is called a *gauge*; but the following form is more frequently employed. A tube six or eight inches in length, sealed at one end and filled with mercury, is inserted in a basin of the same liquid. The mercury is of course supported by the pressure of the atmosphere, and continues to fill the tube. This apparatus is placed beneath a second receiver, communicating with the pipe *d*. During the first stages of the exhaustion, the mercury still remains supported; but so soon as the tension of the contained air becomes less than is sufficient to support the column of mercury, the liquid begins to fall, and the height at which it stands above the level of that in the basin is the measure of the tension of the remaining air. This is called the short Barometer Gauge.

Otto Guericke, a magistrate of Magdeburg, was the first who conceived the idea of rarefying the air in a vessel by means of a pump, about the year 1654. The machine which he constructed was of a very rude kind, but it enabled him to exhibit experiments which at that time were regarded as astonishing. The air-pump was afterwards greatly improved by Hooke and Boyle; and has attained its present state of perfection through the successive inventions of Hauksbee, Smeaton, Cuthbertson, and others.

AIR-VESSELS. Are minute tubes composed of an exceedingly fine transparent membrane, closed at each end, and furnished internally with a delicate elastic thread twisted spirally, whence they are now commonly called spiral vessels. They occur in the medullary sheath, the veins of leaves and of flowers, in the stamens, the ovary, and the seed: their office is to convey oxygenated air.

AIR-VESSELS. In insects, the atmospheric air is conveyed through all parts of the body, for the purposes of respiration, chiefly by means of air-vessels, or *tracheæ*. (*See* that word.)

AISLE, or ALA (Lat. ala, *a wing*.) In Architecture, a term used by the English, more especially, to signify the side subdivisions in a church, usually separated from the nave, or centre division, by pillars or columns; but among different nations it bears different significations as applied to architecture. Strabo informs us, that among the Egyptians, the alæ of the temple were the two walls that inclosed the two sides of the pronaos, and which were of the same height as the temple itself. The walls, he observes, from above ground, were a little farther apart than the foundations of the temple, but, as they rose were built with an inclination towards each other. The right understanding, however, of this passage is attended with difficulty, and seems to have puzzled Pocock no less than ourselves. The Greek alæ, called ptera, were the colonnades which surrounded the cell of the temple, the monopteros temple being the only species which had columns without an interior (to them) wall. The peripteral had one tier of columns round the cell, the dipteral two, and the pseudo or false dipteral, which Hermogenes invented, was that in which the ala was single, but occupied the same space on the sides of the cell as the dipteral, though one of the tiers of columns was left out; thus, by metaphor, the columns were called the alæ, or wings, of the temple. This term is also applied to the sides of a building which are subordinate to the principal, and central division, and are vulgarly called wings.

AITS. Islets, or little islands, commonly planted with osiers, and which are then called willow aits.

AKE'NIUM. *See* ACHÆNIUM.

A LA MIRE. In Music, the name of one of the notes in the modern scale of Guido. (*See* MUSIC.)

A'LA. (Lat. ala, *a wing*.) In Ornithology, the pectoral extremity, the bones of which support broad folds of skin, covered with feathers, and are modified for flight. The under part of the base of the wing, where it joins the body, is termed the *axilla*; the joint between the antibrachium and carpus is termed the flexure or *plica*. The wing is said to be armed (ala calcarata) when the carpus bears one or two horny spurs; to be impennate (ala impennata) when provided with equal, lax plumes, unfit for flight; to be elongate (ala elongata) when, in the folded state, it equals or exceeds in length the body from the base of the bill to the root of the tail; to be middle-sized (ala mediocris) when, in the folded state, the extremity covers the base of the tail; to be short (ala brevis) when, in the folded state, the extremity reaches the sides of the coccyx.

In Entomology, the wings, or organs of aërial progression, are tegumentary productions simply, and consist of a double membrane of a tender and generally transparent consistence, inclosing numerous nervures, or branched tubes of a firmer substance.

These organs present considerable differences of form and structure in the different orders of insects, and also vary in number from two to four.

A'LABASTER. A white semitransparent variety of gypsum or sulphate of lime. It is a mineral of common occurrence, and is manufactured into ornamental vases, and occasionally into small statues. The ancients used it for ointment and perfume boxes. Perhaps the term is derived from ἀ, privative, and λαβὸν, *a handle*, as opposed to vessels with handles. This stone is not slippery, and therefore the derivation is incorrectly referred to ἀ and λαμβανω, as if it were difficult to grasp.

ALANGIA'CEÆ. (Alangi, *the Malabar name of one species*.) A natural order of plants closely akin to myrtaceæ. It consists of Indian species, with aromatic roots and eatable fruit. Their long strap-shaped petals afford one of the principal distinctions between them and myrtaceæ.

ALA'NTINE. An amylaceous substance extracted from the root of the Angelica archangelica.

ALA'RMISTS. In a general point of view, means all those individuals who are particularly prone to take alarm at, and to circulate and exaggerate, any sort of bad news; but the designation is more peculiarly applied to those who take alarm at political innovations or changes.

ALA'TE. (Lat. ala, *a wing*.) When any solid body is bordered by a membranous or leafy expansion.

ALAU'DA. (Lat. alauda, *a lark*.) The name of a Linnæan genus of passerine birds, characterised by the claw of their hinder toe, which is straight, strong, and longer than the others. The birds of this genus are granivorous, and nidificate on the ground. The field-lark Alauda arvensis, L., is a well-known example: they appertain to the conirostral division of the passerine order of Cuvier.

ALB. (Lat. albus, *white*.) A vestment worn by priests in the Roman Catholic church, which differs from the surplice in fitting more closely to the body, and being tied with a girdle: it is also commonly embroidered on the breast with crosses.

ALBA'RIUM OPUS. (Lat.) In ancient Roman architecture, a term imagined by some to have been nothing more than a species of whitewash applied to walls, but not, as we think, correctly. In the passage of the tenth chapter of the fifth book of Vitruvius where he recommends the use of the albarium opus, for the ceilings of baths, he allows tectorium opus as a substitute, so that it was clearly a species of stucco. Its employment at the baths of Agrippa, knowing, as we do, the extent to which luxury was carried in the baths of the ancients, seems to prove that it was a superior sort of stucco, and it is by no means improbable that it was susceptible of taking a polish.

A'LBATROSS. (*See* DIOMEDEA.)

A'LBIGENSES. A sect which arose in the south of France in the latter half of the twelfth century. They have been confounded with the Waldenses, with whom, however, they do not appear to have had any real connection. Their tenets have been very differently described, and probably misrepresented, by their opponents; and great obscurity is thrown upon the subject, by the fact of the appearance of various dissenters from the church of Rome in England and elsewhere, about the same time, whose respective views have not been very accurately discriminated. It is probable that the reformers of the south of France opposed themselves originally to the corruptions in discipline, which began first at that period to draw general attention and animadversion upon the clerical order. Hence a very easy step would lead them to think slightingly of many ecclesiastical ordinances, and the ceremonial observances of religion would seduce them into the adoption of mystical notions about an internal light and assurance, and finally betray them into the wildest extravagancies. Thus they are charged with perpetuating the Manichean doctrines: but Bossuet, who accuses them of inclining to that system on certain points, acquits them of holding what is, after all, the distinguishing tenet of the Oriental heresy—the monstrous doctrine of the two principles.

The origin of the name is doubtful. The Latin name by which Narbonnese Gaul was known in the twelfth century, was Albigesium, which seems to put forth a better claim to the derivation than the town of Albi in Languedoc. In the year 1163, Alexander III. published a decree against these sectarians in a council held at Tours, and another in 1179. On neither occasion, however, did he invoke the assistance of the secular arm. At the close of the century, when the sect was still flourishing, and seemed to be more particularly under the protection of Raymond, count of Thoulouse, Innocent III. commenced the work of its extirpation. He appointed two legates to go through the country and excite the zeal of the clergy and laity against the innovators: he instituted the Dominican order of friars, purposely to preach them down; and finally, in 1207, he addressed himself to Philip Augustus, king of France, exhorting him to eradicate the heresy with the sword. The chief leader of the expedition, which soon assumed the character and name of a crusade, was Simon de Montfort, earl of Leicester, to whom the earldom of Thoulouse was promised by the pope as a stimulus to his exertions. In the siege of that city, however, he was killed. The contest, which was carried on with more or less vigour for many years, and which furnishes the first evidence of the disposition of the church of Rome to employ the extreme of violence against those who dissent from its doctrines, ended in the entire destruction of the Albigenses, about the middle of the thirteenth century. (*See especially* Sismondi, *Hist. des Français*, tom. vi.)

ALBI'NISM. A state in which the skin is white, the hair flaxen, and the iris pink. (*See* ALBINO.)

ALBI'NO. A term originally applied by the Portuguese to negroes who were born mottled or discoloured with white spots. It is now generally applied to persons of a preternatural whiteness of the skin and hair, and a peculiar redness of the pupil of the eye, which is so weak as to be of little use in broad daylight, so that albinos sleep in the daytime, and are only capable of seeing distinctly in the twilight or by moonlight. The disease appears to depend upon a deficiency or morbid state of the rete mucosum over the whole body.

A'LBUM. Literally means any thing white. The term is now generally applied to a book in which persons collect autographs, literary essays, &c. The prætor's album was a white board, on which the edicts of that functionary were inscribed.

ALBUM GRÆCUM. When dogs are fed upon bones, they digest the animal portion, and the earthy parts (chiefly phosphate of lime) are voided in the form of white excrement. This inert matter was formerly used in medicine under the above title.

ALBU'MEN. A peculiar animal matter entering largely into the composition of animal bodies, such as the blood, muscles, bones, &c.; also the chief component of white of egg, to which the term albumen was originally applied, and which well and familiarly illustrates its leading peculiarity, namely, that at a certain temperature it coagulates into a soft white solid, no longer soluble in water. It may be obtained pure by coagulating the white of egg by alcohol, washing it thoroughly with that fluid, and then carefully drying it at 120°. It then appears as a yellow, shining, transparent and brittle substance composed of—

Nitrogen	- -	1 atom	= 14	15·05
Carbon	- -	8	= 48	51·61
Hydrogen	- -	7	= 7	7·53
Oxygen	- -	3	= 24	25·81
		1	93	100·00

The albumen of birds' eggs coagulates at a temperature of 145° to 165°; and when dried, shrinks and becomes brittle and semitransparent, in all respects resembling horn. One hundred parts of the albumen of the hen's egg lose, upon careful drying, about 86 of water, and leave 34 of solid residue. Alcohol, most of the acids, and several metallic salts, also coagulate albumen, and some of the latter are very delicate tests of its presence in animal fluids: subacetate of lead, for instance, renders a solution of 1 part of fresh white of egg in 2000 of water turbid, so that it detects 1 part of dry albumen in 10,000 of water. Corrosive sublimate is also an excellent test of albumen, forming with it a white insoluble compound; hence white of egg has been proposed as an antidote in cases of poisoning by corrosive sublimate.

ALBUMEN. A solid fleshy, bony, or horny substance, secreted in some seeds between the embryo and the seed-skin. It is supposed to be intended for the nutriment of the young embryo when it first springs into life. The part that furnishes the flour of corn, the flesh of the cocoa-nut, the great mass of the seeds of coffee, are albumen. Botanists have remarked that this substance is never deleterious, however poisonous the plant may be by which it is borne.

ALBUMEN OF VEGETABLES. Is a proximate principle, having some of the leading chemical characters of animal albumen.

ALBU'RNUM. (Lat. alburnum, *sap-wood.*) The newly formed and soft part of the wood of exogenous trees, consisting of empty or nearly empty tubes and cells, the sides of which are thin and not indurated; however durable the timber of a plant may be, this part of it is in all cases perishable, the vegetable matter of which it consists having but little power of adhesion, and readily yielding up its carbon to the oxygen of the atmosphere, the consequence of which is speedy decomposition. It is only when the tissue of this part becomes consolidated by the addition of resins, tannin, and various other products, which change its colour from a pale yellow to various other deeper colours, that timber really becomes valuable. In some species this is effected rapidly, as in oak, teak, lignum vitæ, &c.; in others very slowly, or not at all, as in the poplar and willow. Hence the wood of the latter class of trees never acquires any durability. By some writers the alburnum is defined to be "wood only one year old;" this is, however, erroneous. It is through the alburnum principally that the ascending sap of a plant moves; the course of the sap is not, however, confined to the alburnum, but is effected wherever the woody tubes are sufficiently open for it to pass.

A'LCA. The name of a Linnæan genus of anserine birds, characterised by a short, compressed, vertically extended, convex beak, edged along the upper surface, and generally transversely furrowed; feet toti-palmate, and wanting the hinder toe. Recent ornithologists have divided the Linnæan awks or penguins into the subgenera fratercula and alca.

ALCABA'LA, or ALCAVA'LA. A tax formerly imposed in Spain and her colonies, consisting originally of 10, and subsequently of 14 per cent. ad valorem, on all property sold, and payable as often as it changed hands. This monstrous impost, by preventing the sale and transfer of property, necessarily proved in the highest degree injurious. (*See* Ulloa, *Rétablissement des Manufactures d'Espagne*, cap. 3.)

ALCA'LDE. A Spanish officer of justice; from the Arabic kadi, *judge*. In Portugal, Alcayde.

ALCALI'METER. A graduated glass tube employed in determining the quantity of real alkali in commercial potash and soda, by the quantity of dilute sulphuric acid of a known strength which a certain weight of these saturates.

ALCA'MPHORA. A Brazilian herb, the croton perdicipes, whose leaves are used in decoction against syphilis, and as a diuretic.

ALCANTA'RA, Order of: otherwise called of Saint Julian, or of the Pear-tree. An order of knighthood, instituted in 1156 at Alcantara, a town of Estramadura, by Hadrian II. king of Leon. The king of Spain is sovereign of this order

ALCARA'ZZA. A porous vessel used in Spain for cooling water by its transudation and consequent superficial evaporation.

ALCE'DO. (Lat. alcedo, *supposed to be the king fisher.*) The name of a Linnæan genus of picæ, charac

terised by a long, straight, angular and pointed beak; the tongue and tail very short. The feet have the structure which is the basis of Temminck's order Syndactyli, viz. the external toe is nearly as long as the middle one, and is united thereto as far as the penultimate articulation. The kingfisher, Alcedo ispida, is a familiar example of that genus. The Alcedo tridactyla, and some others, are remarkable for the absence of the inner toe; these have accordingly been separated from the Linnæan genus under the subgeneric term ceyx. A third subgenus, dacelo, receives the great laughing kingfisher of New Holland.

A'LCHEMY. An imaginary art, once much practised among modern nations, and even now perhaps not wholly exploded. The name is a mixture of Greek and Arabic; the last syllables being from the same root with *chemistry*, *chemist*, Fr. *chimie:* probably the verb cheein, *to pour*, although the intermediate stages of its derivation are disputed: the prefix being the Arabic article al, *the*. Whether alchemy was followed as an art among the classical ancients, seems questionable: some suppose it to have originated among the Arabs of the Califate. Its object was the production of gold and silver. The principle of the alchemists was, that the baser metals were all convertible into these two precious substances by a long series of processes. To this fundamental notion the common followers of the art added an infinity of fantastic imaginations respecting the influence of the planets, &c. in hastening or retarding the work. The instrument by which it was supposed that this mighty change was to be effected, was a certain mineral to be produced by these processes, which, being mixed with the base metal, would transmute it; and this was called the lapis philosophorum or philosopher's stone. Hence the term *adept*, adeptus, for him who was supposed to have attained the secret of alchemy; who had, in the Latin force of the word, gained or discovered the philosopher's stone. Innumerable instances are on record of persons who practised on the credulity of former times by professing to possess this stone, and who actually wrought the transmutation required; and it is supposed that the philosopher's stone employed by these personages was nothing more than an amalgam of gold, which, if projected into tin and cupellated, would leave a portion of the precious metal. Dr. Price, of Guildford, is said to have been the last person in this country who professed himself able to turn mercury into gold: he destroyed himself in 1782, to avoid, it was supposed, the detection of his deceptions. The alchemists, in the course of their endless experiments, are said to have served the cause of true science in many ways. To various adepts is ascribed the discovery of the concentrated acids and of phosphorus. Another object of the adepts, often pursued by them, together with their research after transmutation, was the discovery of the elixir vitæ, or supposed universal medicine. Alchemy is also denominated the Hermetic Art, from the imaginary sage, Hermes Trismegistus.

A'LCOHOL. A term of Arabic origin, implying the spirit, or essence, and originally applied to several chemical preparations. It is retained in modern chemistry to signify pure spirit of wine.

Fermented liquors were known in the earliest ages. The northern nations were probably acquainted with the art of obtaining spirits before the Greeks or Romans. Albucasis, in the twelfth century, taught the method of procuring spirit from wine; and Raymond Lully, in the thirteenth century, concentrated spirit of wine by carbonate of potash. The composition of alcohol was first accurately demonstrated by Lavoisier, and its analysis was perfected by Saussure.

Alcohol is exclusively produced by the process of fermentation: it is obtained in combination with water by distilling fermented liquors, such as wine, beer, wash, &c.; the liquor thus obtained (brandy, for instance, if from wine,) is redistilled, and the spirituous portion, being most volatile, first passes over; in this state it is called ardent or rectified spirit, and often contains acetic acid and a peculiar flavouring principle, probably of an oily nature: these are got rid of by redistillation with alkaline substances, charcoal, chloride of lime, &c.

Pure or absolute alcohol is obtained by distilling the purest rectified spirit off dry and warm carbonate of potash, or dry quicklime. The specific gravity of rectified spirit is 820 to 828; that of alcohol, 792, at the temperature of 60°.

Pure alcohol has an agreeable odour, a strong pungent taste, and is eminently intoxicating. It consists of

Carbon	- 2 atoms	= 12	52·18
Hydrogen	- 3	= 3	13·04
Oxygen	- 1	= 8	34·78
	1	23	100·00

Alcohol burns with a pale flame, and produces carbonic acid and water; the weight of the water thus formed to that of the alcohol consumed, is as 27 to 23. It produces no smoke or soot, and hence forms a cleanly lamp, giving much heat with little light. Mixed with water and certain vegetable substances, especially gluten, and exposed to air and a due temperature, alcohol becomes vinegar. It is the intoxicating principle of wine and of fermented and spirituous liquors, and of important use in medicine and in some of the arts, being the solvent of various resins for varnishes, &c. When alcohol and water are mixed, heat is evolved, and condensation ensues, and it is some hours before the two liquids perfectly unite. So that the bulk of a pint of alcohol and a pint of water falls far short of two pints. A series of tables by Mr. Gilpin will be found in the Philos. Trans. for 1797, exhibiting much information upon the subject of the specific gravities and composition of various mixtures of alcohol and water,—a subject of great importance, as bearing upon the levying of duties upon spirituous liquors.

Alcohol has never been frozen; hence its use in the construction of thermometers for measuring low temperatures. It boils at the temperature of 176°, and is converted into a vapour, the specific gravity of which is to that of air as 16 to 10.

A'LCOHOLATES. Salts in which alcohol appears to replace the water of crystallisation.

A'LCORAN, or ALKORAN. (Al Koran, or *the Book*, Arabic.) The sacred book of the Mohammedans; which, according to their belief, was dictated to their prophet by the angel Gabriel. The Koran consists of 114 chapters; which are distinguished, not by their numerical order, but by certain titles, under which they are respectively known. Every chapter is divided into smaller portions, analogous to the verses of our Scriptures. There are, however, seven principal ancient copies of the Koran; and in all of these the number of verses is not the same. The Koran is written in what may be termed a species of chiming or jingling prose. It is regarded among the Mohammedans as in itself a standing miracle, and a proof of the truth of their religion; and hence the division between those who believe the Koran to be eternal and uncreated (the Sonnites or orthodox), and various sects of heretics.

ALCO'VE. (Alcoba, Sp., Elcaut, Arab., *a sleeping chamber.*) In Architecture, that part of a sleeping chamber where the bed is placed. The use of alcoves, though not by that name, is ancient. They were frequently designed in the form of a niche; such, for instance, as those that Winckelman notices at Hadrian's villa at Tivoli, of which species some are also to be seen at Pompeii. They were often formed by an enclosure or balustrade, sometimes high and sometimes low, through which, by means of draperies, this part was separated from the large chamber, whereof it was a part. A notion of it may be obtained from many of the ancient bassi rilievi, especially from the celebrated one known by the name of the Nozze Aldobrandine. In modern architecture, this part of a room differs according to the rank and taste of the proprietor; in England it is rarely used, but in France and Italy it forms frequently a beautiful feature in the apartments of their palaces.

A'LCYONITES. A collective term for the fruit-like spongiform flint fossils common in chalk formations.

ALCYO'NIUM. A Linnæan term for an aggregate genus of marine polypes, having a fleshy, coriaceous, spicular axis, beset with stellate cells, containing each a polype with eight radiate denticulate arms. The axis is fixed to foreign bodies, and in some species rises in short branches or lobes, as in that commonly known by the name of "Dead Man's Hand" (Alcyonium digitatum, *Lin.*; Lobularia digitata, *Lam.*)

A'LCYONS. (Gr. ἀλκυων, *a kingfisher.*) The name given by Temminck to an order of birds of which the kingfisher (alcedo) is the type.

A'LDER. (Ellarn in Anglo-Saxon.) A native tree belonging to the natural order Betulaceæ. It is chiefly found in damp situations, and is of little value except for hurdle wood, and for the manufacture of charcoal.

A'LDERMAN. Originally written ealdor-man, meaning elder-man, which was used in the earlier parts of the Saxon period as a name of dignity unconnected with office; it was also the original title of the officer who was subsequently styled earl, whence counties were sometimes called alderman-shires. It seems also to have been the designation of the chief magistrate or judicial functionary of minor districts, in which sense it first appears in connection with boroughs. Its application is now confined to the class of municipal officers in a borough next in order to the mayor. By 5 & 6 W. 4. c. 76., the aldermen are to be in number one-third of the councillors in every borough (London alone being excepted from the provisions of the act), one part to be elected triennially, on the 9th of November, from among councillors or persons qualified to be such; and to form, with the mayor and councillors, the council of the borough.

A'LDINE EDITIONS. In Bibliography, those which proceeded from the press of the family of Aldus Manutius. The first of that name established his press at Venice, not

long after the year 1490; and to his industry and zeal we owe several of the first editions of Greek authors, and many other valuable works. The Italic characters used in Roman printing by Aldus and his family, first appear in his Virgil of 1501; and from that period a series of works, chiefly classical, both Greek and Latin, proceeded from his press in a duodecimo form: these are the best known and most common Aldine editions. The family press is said to have been broken up in 1597, after producing 908 editions. There are, however, Venetian publications of the beginning of the 17th century which bear the impress of the Aldine family (an anchor and dolphin engraved on the last page). A branch of the Aldine press was for a short period established in Rome. (*See* Raynouard, *Annales de l'Imprimerie des Aldes.*)

ALE. *See* Beer.

ALEATO'RIUM. (Lat.) In ancient Roman architecture, an apartment appropriated to the use of players with dice or aleæ.

ALECTO'RIDES. (Gr. ἀλεκτωρ, *a cock.*) A tribe of rasorial or gallinaceous birds, including the curassow, and the species which, like it, resemble the common fowl in the form of the beak.

ALE'MBIC. (From the Arabic particle al, *the*, and ambeeq, corrupted from the Greek word ἀμβιξ, *a cup or vessel.*) An obsolete form of still. Constructed upon a small scale in glass, it is sometimes used in the laboratory.

ALE'MBROTH, or Salt of Wisdom. A term applied by the old chemists to a salt composed of ammonia, muriatic acid, and oxide of mercury. It is poisonous.

ALEXA'NDRIAN SCHOOL. An academy for literature and learning of all kinds, instituted at Alexandria by Ptolemy, son of Lagus, and supported by his successors. The grammarians and mathematicians of this school were particularly celebrated. In the former class occur the noted names of Aristarchus, Harpocration, and Aristophanes; and among the latter were numbered the astronomer Ptolemy, and geometer Euclid. The grammarians of Alexandria exercised a universal literary jurisdiction, publishing canons of those who were to be considered standard authors, and revised editions of ancient writers. For some account of the famous collection of books at Alexandria, *see* Library.

ALEXA'NDRINE. The French heroic verse of twelve syllables or six Iambic feet. In English poetry it is occasionally used: by Dryden, sometimes as a second line in a heroic couplet, more frequently as a third line in a triplet; and the Spenserian stanza necessarily concludes with an Alexandrine. The lines of Pope, defining the Alexandrine by an example, are well known:

"A needless Alexandrine ends the song,
Which, like a wounded snake, drags its slow length along."

ALEXIPHA'RMIC. (Gr. ἀλεξω, *I avert*, and φαρμακον, *a poison.*) Antidotes to poisons.

ALEXITE'RICS. (Gr. ἀλεξω, *I avert.*) Preservatives against contagious and infectious diseases and the effects of poisons in general.

A'LGÆ. (Lat. alga, *sea-weed.*) Plants which are destitute of all signs of sexual organs, and which vegetate exclusively under water. When they grow in salt water they are called sea-weeds, when in fresh water they are named confervæ. They comprehend in the division Zoospermeæ some of the lowest known forms of vegetable life, plants consisting of simple cells adhering in different degrees, and emitting at maturity spores or seeds having a distinct animal motion. In the case of Oscillatorias, the whole mass of the plant writhes and twists spontaneously; and Zysmenas actually copulate. It is in this part of the vegetable kingdom that plants approximate to animals in the most striking degree. An excellent account of the salt-water species is given in Greville's Algæ Britannicæ; the fresh-water kinds may be studied in the third volume of the English Flora.

ALGARO'BA. (Arab. al, *the*, and garoba, *a bean-tree.*) A tree found in the southern parts of Europe, and in Palestine, having pods filled with a sweetish nutritious powder: they are supposed to have been the locusts on which St. John fed in the wilderness. It is the ceratonia siliqua of botanists.

A'LGAROTH, POWDER OF. The white powder which falls when chloride of antimony is dropped into water: it is a submuriate of antimony, virulently purgative and emetic.

A'LGEBRA. An important branch of the mathematical sciences, and may be defined to be the method of calculating indeterminate quantities. It is a sort of universal arithmetic, founded on the same principles as common arithmetic, and proceeding by rules and operations precisely similar. But it is not confined merely to questions relating to numbers, being applied generally to investigate the relations that subsist among quantities of all kinds, whether arithmetical or geometrical. The reasoning is carried on by general symbols; and it is to the complete system of notation, which has been introduced by its successive cultivators and improvers, that it owes its immense superiority over the ancient analysis.

The symbols employed in algebra are of two kinds: those which denote quantities; and those which denote the affections or relations, or properties of quantities, and operations to be performed on them. For representing quantities or magnitudes, the letters of the alphabet are employed. Thus, in the solution of an arithmetical problem, a number may be represented by the letter a; in geometry, a may represent a line or an angle; in mechanics, a force. The relations of quantities are expressed by other conventional symbols. The relation of equality is expressed by the sign $=$; thus, to express that the quantity represented by a is equal to the quantity represented by b, we write $a = b$. The symbol $>$ or $<$ coming between two quantities denotes inequality; thus, $a > b$ signifies that a is greater than b, and $a < b$ denotes that a is less than b. The two primary operations of which quantities are susceptible, are addition and subtraction, and these are respectively indicated by the symbols $+$ plus, and $-$ minus. For example, $a + b$ denotes the sum of the two quantities a and b, or that a is to be increased by b; and $a - b$ denotes the difference between a and b, or that a is to be diminished by b. Multiplication is indicated by the symbol $\times$, or by simply placing the letters beside each other without an intervening symbol. Thus, in numbers, $a \times b$ or $a\,b$ denote the same thing, namely, the product arising from the multiplication of the number a into b. In geometry, two letters joined together, as $a\,b$, denote a rectangular parallelogram, one of the sides of which is represented by a, and the other by b. Division is indicated by $\div$; or more frequently by placing one of the numbers above the other in the form of a fraction; thus:

$$30 \div 10, \text{ or } \tfrac{30}{10}.$$

In addition and subtraction, the quantities connected by the appropriate symbols must be homogeneous, or of the same kind; for it is only such quantities that admit of addition or subtraction. Of two quantities connected by the symbol of multiplication, one must necessarily be an abstract number, for a quantity can only be multiplied by a number, or, which is the same thing, added to itself once or twice, or some other number of times. When division is to be performed, the divisor may either be a quantity of the same kind as the dividend, or it may be an abstract number; in the former case, the quotient is an abstract number; in the latter, it is a quantity of the same kind as the dividend.

In the multiplication of quantities, the frequent repetition of the same symbol would become inconvenient; it is usual, therefore, to write the root only once, and to place over it, on the right, the exponent or number indicating the power: thus, a^2 denotes the same thing as $a\,a$, or the square of a; a^3 is the same as $a\,a\,a$, or the cube of a, and a^n denotes the nth power of a, or a multiplied by n times into itself. By analogy, $a^{\frac{1}{2}}$ denotes the square root of a; $a^{\frac{1}{3}}$ the cube root of a, and so on. (*See* Notation, Symbol.)

Algebra is in its nature essentially distinct from arithmetic. In arithmetic absolute numbers are given, from which other absolute numbers are required to be determined. But in algebra the symbols that are employed are perfectly general, and may represent any numbers whatever; and the expressions which result from combining them according to the conditions of the problem, indicate the solution not of a particular question, but of all questions whatever, in which numbers are subjected to the same series of operations. In this manner the general properties of numbers are discovered. For example, the expression $(a + b)\,(a - b)$, which signifies that the sum of the two numbers a and b is to be multiplied by their difference, becomes, on performing the multiplication, $a^2 - b^2$; whence we infer this general or universal truth, namely, that the product of the sum and the difference of any two numbers, is equal to the difference of the squares of those numbers. Arithmetic could only prove the property to be true in respect of particular numbers. The systematic notation, to which algebra owes nearly the whole of its power as an instrument of research, is only of recent introduction. Indeed, the science itself, if known at all to the ancient Greek mathematicians, was known only as a higher species of arithmetic. The first writer on the subject, with whose works we are acquainted, is Diophantus, who lived about the middle of the fourth century of our era, and his work relates only to a peculiar class of arithmetical questions, in the solution of which he displayed considerable address, but the symbols which he used were only abbreviations (such as the initial or terminating letters) of the ordinary words. The treatise of Diophantus passed into the hands of the Arabians; but algebra received from them no improvement or extension. From the Arabians, it was transplanted into Italy, in the beginning of the 13th century, by Leonardo Bonacci, a merchant of Pisa, who had travelled frequently in the East, and become acquainted with the science of those countries. A treatise on arithmetic, comprehending algebra as it was then

known, was written by him in the year 1202, and from that time the science appears to have been cultivated with some assiduity in Italy. The earliest printed book on the subject was composed by Lucas Paciolus, or Lucas de Burgo, a minorite friar, and appeared in 1494. It contains a pretty complete treatise on algebra for the time; but exhibits the science in nearly the same state in which it was left by Diophantus. Its application was confined to questions relating to numbers of no great interest, and its power extended only to the solution of equations of the first and second degrees. But after this epoch it began to be cultivated extensively, and to undergo rapid improvement. Scipio Ferreus, a professor of mathematics at Bononia, about the year 1505, first broke through the boundary within which it had so long been confined, and accomplished the solution of a problem of the third degree. A general method of solving cubic equations was soon after discovered by Tartalea, who communicated it, under an oath of strict secrecy, to the celebrated Cardan. Presuming on some improvements he had made in the rules given to him by Tartalea, and on the demonstrations which he certainly had the merit of inventing, Cardan, with a remarkable (though, unfortunately, in the history of science not singular) instance of bad faith, published the whole as a supplement to a treatise which he had composed several years before. Cardan, however, considerably extended the methods given to him by Tartalea, and, besides, contributed to improve the notation, by frequently employing the letters of the alphabet. Lewis Ferrari, a disciple of Cardan, had the honour of making the next important improvement in the science, by the discovery of a method of solving biquadratic equations, or equations of the fourth degree; and it is remarkable that all the efforts of modern mathematicians have not yet been able to pass this barrier, or effect the general solution of equations of a higher order than the fourth.

The first great step to the improvement of algebra, by the introduction of a concise and systematic notation, was made in Germany, by Stifel, or Stifelius, a protestant minister, whose work, "Arithmetica Integra," was published in 1544. Stifel adopted the symbols $+$ and $-$ for plus and minus, to represent addition and subtraction, and also $\surd$ (the contraction of r) for radix, or root: he likewise introduced the numeral exponents of the powers, $-3, -2, -1, 0, +1, +2, +3$, &c. The symbol $=$, denoting equality, was first used by our countryman, Robert Recorde.

In following the chain of the principal discoveries, our attention is next arrested by Vieta, a native of France, who first applied algebra to the improvement of geometry, and thereby laid the foundation of the modern analysis. He was also the first who employed general symbols to represent known, as well as unknown, quantities, and thus introduced what has been called the specious algebra, in contradistinction to the literal, where known quantities are represented by numbers. This improvement, simple as it may appear, was attended by important consequences, as it rendered the methods quite general, and enabled the algebraist to comprehend whole classes of problems in a single formula. Vieta likewise gave a method of solving algebraic equations by approximation; and from his doctrine of angular sections have been derived the arithmetic of sines, and some of the most valuable processes of trigonometry.

Vieta was followed by Albert Girard, who first showed the use of the negative sign in the solution of equations; and by Harriot, to whom the science is indebted for the very important discovery, that every algebraic equation may be regarded as the product of as many simple equations as there are units in the number expressing its order. An equation, for instance, of the fifth degree may be regarded as the product of five simple equations. Descartes followed soon after, and opened up vast fields of discovery, by the application of the algebraic analysis to define the nature and investigate the properties of curve lines. By referring every point of a curve to co-ordinate or perpendicular axes, he expressed the relation between its different points by means of an equation, which served as a characteristic to distinguish the curve, and from which its different properties could be investigated by the ordinary operations of algebra. Descartes also pointed out the method of constructing or representing geometrically, equations of the higher orders; gave a rule for solving a biquadratic equation by means of a cubic and two quadratics; and improved the methods of reducing and treating equations which had been adopted by Cardan, Girard, Harriot, and others who had preceded him.

Algebra, as a science, has undergone no revolution since the time of Harriot and Descartes; but it has been improved in all its details, and greatly varied and extended in its applications. During the last century, and the latter part of the preceding, the method of infinite series, so useful in many applications of mathematics, particularly in the calculation of probabilities, was successfully cultivated by Wallis, Newton, the Bernoullis, Euler, De Moivre, Stirling, Simpson, and others. The nature and composition of algebraic equations has been fully investigated, and the methods of approximating to their roots reduced to order and system. The investigation of the relations of angular sections, begun by Vieta, conducted Euler to the arithmetic of sines and a complete theory of plane and spherical trigonometry. Applied to problems concerning the motion of bodies or points, algebra has given rise to the doctrine of fluxions, and the refined methods of the differential and integral calculus. It has completely superseded the use of the elegant, but comparatively feeble, ancient analysis, and may be now regarded as forming the basis of the whole edifice of mathematical science. (*See* BINOMIAL THEOREM, EQUATION, NOTATION.)

ALGEBRA'IC CURVE. A curve of which the relation between the abscissa and the ordinates is expressed by an equation which contains only algebraic quantities. The term algebraic is here used in contradistinction to transcendental, under which is comprehended infinite series and quantities of the following kind: log. x, a^x, sin. x, cos. x, tan. x, &c.

ALGEBRAIC EQUATION. An equation of which the terms contain only algebraic quantities. (*See* EQUATION.)

A'LGORITHM, signifies the art of computing in reference to some particular subject, or in some particular way; as the algorithm of numbers; the algorithm of the differential calculus.

A'LGUAZIL. A Spanish officer corresponding with the English bailiff, having power to place persons in custody, and apprehend criminals.

A'LIAS. (Lat. *otherwise*.) In Law, when a defendant sued on a specialty, or a prisoner, had more than one common appellation, he was designated in the Latin forms of instruments, as "A. alias dictus B." When it is necessary for a second writ of the same description with a former one to issue, it is headed "alias," as, an alias capias, &c.

A'LIBI. (Lat. *elsewhere*.) A cant law phrase, used to express the species of defence set up by one charged with a criminal offence, who offers evidence to prove that he was elsewhere at the time of the act committed.

A'LIDADE. An Arabic name given to the index or ruler which moves about the centre of an astrolabe or quadrant, carrying the sights or telescope, and showing on the limb of the instrument the number of degrees and minutes the object observed is elevated above the horizon.

A'LIEN, generally speaking, is one born in a country out of the allegiance of the sovereign, unless his father were a natural born subject, in which case he will himself be deemed a natural born subject, to all intents and purposes. An alien in England cannot hold landed property, but he may hold and dispose of, by will or otherwise, goods, money, or other personal estate, and may take a lease of a house for habitation or trade. An alien may, by letters patent, become a denizen, and take lands by purchase; or he may be naturalised by act of parliament, and so take by inheritance. In either case he becomes an English subject, but, nevertheless, cannot be a member of the privy council or parliament. (*See* DENIZEN.)

ALIEN WATERS. Any stream of water carried across an irrigated field or meadow, but which is not employed in the process of irrigation.

ALIENA'TION. In Law, the act of parting with property: more especially real property. The alienation of real property takes place by deed, or in pais. (*See* REAL PROPERTY.)

ALIME'NTARY CANAL. A cavity in the interior of an animal body in which the nutriment is taken to be digested, before it is conveyed by the nutritive vessels to the system: it affords the best organical characteristic of an animal, but presents various modifications of structure. Sometimes it is a simple cavity with one opening; sometimes a true canal, with an outlet or anus, distinct from the inlet or mouth; this canal may be divided into stomach and intestine, as in the oyster; or a mouth, pharynx, and œsophagus may precede the stomach; the œsophagus, again, may have one or two sacculi appended to it, called crops. The stomach may be subdivided into four bags, as in the ruminants, or into seven, as in the bottle-nose whale; and the intestines into small, blind, and large, forming, with their subdivisions, what are termed duodenum, jejunum, ileum, cæcum, colon, and rectum. The cæcum, again, may be single, or double as in most birds; or a single cæcum may exist in addition to a double one, as in the hyrax, a small pachydermatous quadruped. Lastly, the various glandular organs which communicate with the alimentary canal are to be regarded as cæcal processes of that tube, since these are developed from it, and in this condition they are permanently retained by one or other of the lower animals: thus, in the sea-mouse, the liver is represented by long, branched, lateral processes of the intestine; in the cod fish, &c. the pancreas is similarly represented by numerous cæcal processes of the duodenum.

A'LIMONY. In Law. The allowance for which a

married woman is entitled to sue on separation from her husband. (*See* MARRIAGE.)

A'LIQUOT PART of a number. A number which divides the given number without leaving a remainder. Thus 2, 3, 4, and 6, are aliquot parts of 12. To find the aliquot parts of any number, divide the given number by its least divisor; divide the quotient also by its least divisor, and so on, always dividing the last quotient by its least divisor till the quotient is 1. The divisors thus used are the prime aliquot parts of the given number; and the products of every two, every three, every four, &c. of the prime aliquot parts, give the compound aliquot parts of the given number. Suppose the given number 30; divide 30 by its least divisor, which is 2, and the quotient is 15; divide 15 by its least divisor 3, and the quotient is 5; divide 5 by itself (it has no smaller divisor) and the quotient is 1. Therefore, 2, 3, and 5, are the prime aliquot parts of 30. The compound aliquot parts are, $2\times3=6$, $2\times5=10$, $3\times5=15$.

ALISMA'CEÆ. (Alisma, from alis, *water*, in Celtic.) A small natural order of endogenous plants, marked by the presence of numerous distinct carpels in a tripetaloideous flower. They form a near approach to ranunculaceæ among exogens. Alisma and sagittaria are common genera.

ALI-TRUNCK, ALITRUNCUS. In Entomology, the posterior segment of the thorax of an insect to which the abdomen is affixed, and which bears the legs, properly so called, or the two posterior pairs, and the wings.

ALIZARINE. From Ali-zari the commercial name of madder in the Levant; a peculiar colouring principle obtained from madder.

A'LKAHEST. A term of obscure Arabic origin, applied by the alchemists to a supposed universal solvent.

A'LKALI, or ALCALI, derived from the Arabic article al, and kali, the name of a plant in the same language. A term originally applied to the ashes of plants; now generally used to designate potash, soda, and ammonia, which are also termed vegetable, mineral, and volatile alcali. These substances have certain properties in common, such as neutralising and forming salts with the acids, reddening several vegetable yellows, and changing some blues to green, and ready solubility in water. Lime, baryta, strontia, and magnesia, have been called alcaline earths, from their analogous action on vegetable colours. Lithia is also one of the alcalis. A singular class of bodies have been discovered in vegetables which have been termed alcalis, or alkaloids, chiefly in consequence of their power of saturating and forming definite salts with the acids. Morphia, quinia, &c. are substances of this description.

ALKALI, FOSSIL or MINERAL. Soda.

ALKALI, PHLOGISTICATED. Ferrocyanuret of potassium.

ALKALI, VEGETABLE. Potash.

ALKALI, VOLATILE. Ammonia.

A'LKALOI'DS. Substances analogous to alcaline bases of vegetable origin, and generally possessed of great medicinal activity. Their ultimate elements are carbon, hydrogen, oxygen, and nitrogen. The principal substances of this class, together with the plants from which they are obtained, are the following:—

Aconita - -	Aconitum napellus.
Aricina - -	A bark from Arica.
Atropia - -	Atropa belladonna.
Brucia - -	Strychnos nux vomica.
Cinchonia - -	Cinchona lancifolia.
Codeia - -	Opium.
Conia - -	Conium maculatum.
Corydalia - -	Corydalis tuberosa.
Cynapia - -	Æthusa cynapium.
Daturia - -	Datura stramonium.
Delphia - -	Delphinium staphisagria.
Digitalia - -	Digitalis purpurea.
Emetina - - -	Cephaelis ipecacuanha.
Hyoscyamia - -	Hyoscyamus niger.
Meconia - -	Opium.
Morphia - -	Opium.
Narcotina - -	Opium.
Nicotina - -	Nicotiana tabacum.
Picrotoxia - -	Menispermum cocculus.
Quinia - - -	Cinchona cordifolia.
Sanguinaria - -	Sanguinaria canadensis.
Solania - -	Solanum nigrum.
Thebaia and Narceia	Opium.
Veretria - -	Veratrum sabadilla.

A'LKANET. (A corruption of the French *orcanette; orca, a rouge pot.*) A kind of reddish purple dye, obtained from the roots of Anchusa tinctoria: it was formerly used for staining the face.

ALKANET. The Anchusa tinctoria. The root of this plant, which is a native of the warmer parts of Europe, contains a red resinous colouring matter which it imparts to alcohol and oils: it is used to tinge some ointments, especially lip-salves, of a red colour.

ALKOO'L. A preparation of antimony used by the women of eastern nations, to tinge the eyelids and lashes of a black colour. Dr. Shaw, speaking of the women in Barbary, says, " None of these consider themselves dressed, till they have tinged the edges of their eyelids with alkoohl. "

A'LLA BREVE. (Ital. according to the breve.) In Music, the name of a movement whose bars or measures consist of the note called a breve, equal therefore to two semibreves or four minims. It is denoted at the beginning of a staff by a C with a bar drawn through it vertically.

A'LLA CAPELLA. (Ital. according to the chapel.) In Music, the same as alla breve. The name originates in the circumstance of this time being principally employed for movements used in the church or chapel.

A'LLAH. The Arabic name of the Supreme Being. It signifies the True God, as opposed to the deities of idolaters.

A'LLANITE. A silico ferriferous oxide of cerium from Greenland; named after the late Mr. Allan of Edinburgh.

ALLA'NTOIC ACID. A white crystallisable acid, obtained by evaporating the allantoic liquid of the fœtal calf.

ALLA'NTOIS. (Gr. *αλλας, a sausage* and *ἑιδος, form.*) A thin membranous sac developed from the termination of the alimentary canal of the embryo, situated between the amnion and chorion, and organised by the hypogastric arteries and umbilical vein. Its function, as a temporary respiratory organ, is of most importance in those oviparous vertebrates where the embryo has no branchiæ; in the mammalia, its use is more or less superseded by the chorion and placenta. In some quadrupeds the allantois has the form of a sausage; whence its name.

ALLE'GIANCE. (Fr. ligence, from the Latin ligare and allegare, *to bind.*) The obedience which a citizen owes to his prince or country. The allegiance of a born subject of the English Crown is inseparable, and follows him every where: nor can he by any act of his own free himself from it. There is also a temporary allegiance, which foreigners incur so long as they reside within the king's dominions. By common law, all persons above the age of twelve years were required to take the oath of allegiance at the court leet; and the oaths of allegiance and supremacy have since been imposed by many statutes. The present form of the oath of allegiance was introduced by the Convention Parliament of 1688. In the United States, it appears to be regarded as a doubtful point, whether the allegiance of the citizen is necessarily perpetual, as with us. The American laws also require a foreigner to have renounced (as far as possible by his own act) allegiance to his former government, two years before he takes the oath of allegiance to that of his acquired country.

A'LLEGORY. In Rhetoric and Literature (from the Greek words *ἀλλο, another thing*, and *ἠγορεω, I declare.*) has been defined, " a figurative representation, in which the signs (words or forms) signify something beyond their literal or direct meaning. In this sense allegory may be addressed to the eye, in painting and sculpture, by means of forms, intended to convey, besides the notion of those sensible objects which they represent, certain abstract ideas to which these objects are supposed to bear analogy. Allegory differs, 1. from symbolical writing or representation; because in the first, the type and antitype, or thing exhibited and thing intended, have some real or natural resemblance, relation, or analogy: in the latter, the resemblance is merely conventional. Thus, to take an instance from modern literature: if it be true, as is now alleged, that the earlier Italian poets of the middle ages, and Dante in particular, attached a conventional meaning to certain ideas frequently recurring in their poems; as, for example, that Satan signified the papal power,—the three beasts mentioned in the commencement of Dante's poem three States — love, loyalty to the emperor, &c. &c.; then their poems, considered with reference to this occult sense, must be regarded as specimens not of allegory but of symbolical writing. But if, as in the more ordinary interpretation of Dante's poem, Satan represents the abstract idea of eternal misery, the beasts particular vices, &c., which in common acceptation are supposed to have some natural analogy with their representatives, the poem is in this respect to be regarded as an allegory. Thus, also, critics have endeavoured to give a symbolical sense to the sixth book of Virgil's Æneid; while, independently of that sense, if it really exist, there is an obvious allegorical meaning running through the whole. (In ancient criticism, however, the words allegory and symbol were not so accurately distinguished; and in our translation of the Bible, St. Paul is made to use the word allegory in the clear sense of type. Gal. iv. 24.) Allegory differs, 2. from parable, only inasmuch as the latter is a species of the former: a parable being a short, sententious, allegorical narration. And, 3. it is different from metaphor, being in effect a chain of metaphors, or a single metaphor continued and wrought out into a lengthened discourse.

4. Fables may also be mentioned as a species of allegory. (*See* FABLE.) An allegory, or allegorical tale, in the somewhat narrower sense in which the term is used in literature, is generally a tale in which abstract ideas are personified: such (to cite one of the earliest instances of this species of composition) as the Choice of Hercules, or human youth, between virtue and vice, in the shape of two females: an allegory which descends to us from Greek antiquity. Entire poems are sometimes strictly allegorical, as that of Spenser; or entire narratives, as Bunyan's Pilgrim's Progress; in which case it requires consummate art to keep up the propriety of the allegory, which is in fact a compound of two opposite, and sometimes scarcely compatible, qualities—consistency running through its several incidents, when considered merely as a narrative and without reference to the ulterior meaning, and consistency of analogy between the thing represented and the thing answered.

ALLEGR'ETTO, and ALLEGRO. (Ital. *a little merry*, and *merry*.) In Music. The first term is a diminutive of the second, which, prefixed to a movement, signifies that it is to be performed in a brisk and lively manner; not, however, with hurry or precipitation, but quicker than any other time in music, except that marked presto. The different times used in music are arranged as follows: proceeding from slow to quick, namely grave, adagio, allegretto, allegro, and presto. The word più, *more*, added to any of these, and the word poco, *little*, strengthen the significations in their various kinds.

A'LLEMAND. (Fr.) In Music. A species of slow grave music or movement in common time and performed slow. From its name it would seem to belong to Germany, but it is now altogether disused.

ALL-HA'LLOWS. The old English name for All Saints' day (the 1st of November).

ALLIA'CEOUS. (Lat. allium, *garlic*.) Any thing having the smell of onions or garlic.

ALLIACEOUS PLANTS. Plants which partake more or less of the qualities of garlic and onions; such as onions, shallots, rocambole, chives, leeks, garlic, &c.

ALLI'ANCE. In Politics and International Law, a league between two or more friendly powers; which may be either offensive and defensive, or defensive only. Of the former species is the alliance of 1813 against Napoleon, subsequently called the Holy Alliance. Of the latter, the Quadruple Alliance, concluded in 1833 between England, France, Spain, and Portugal. Alliances are divided by publicists into three classes. 1. Those in which the allied parties agree to prosecute a war with their whole force. 2. Alliances in which auxiliary states pledge themselves to grant to a principal state a fixed contingent of men, money, &c. 3. Treaties to furnish troops for stated subsidies, to make advances of money, &c.

ALLIGA'TION. (Lat. alligo, *I bind*, or *tie together*.) A rule of Arithmetic, for the solution of questions concerning the compounding or mixing together of different ingredients, or ingredients of different qualities. There are two cases, one of which is alligation medial, and the other alligation alternate. To the first case belongs a question of this sort: Suppose 4 gallons of wine at 12 shillings per gallon, to be mixed with 6 gallons at 17 shillings per gallon, what is the worth of a gallon of the mixture. But if it were asked, how many gallons of wine, at 17 shillings per gallon, must be mixed with 4 gallons at 12 shillings per gallon, in order that the worth of a gallon of the mixture may be 15 shillings, the question would belong to alligation alternate. Questions of this kind are, however, most easily resolved by elementary algebra; of which they form an easy class of indeterminate problems, admitting in general of an indefinite number of solutions.

A'LLIGATOR. (A corruption of the Portuguese word 'lagarto,' which is derived from lacerta, *a lizard*.) In modern Zoology, the term is limited to those species of crocodile which have a wide obtuse muzzle, unequal teeth, the fourth pair of which, counting backwards in the lower jaw, pass into corresponding cavities in the upper jaw, where their points are concealed when the mouth is closed. In the true crocodiles, the corresponding teeth pass into open grooves in the margin of the upper jaw, and are consequently exposed. In the alligators the head is less oblong, its length being generally as to its breadth as 3 to 2: the teeth are more numerous than in the crocodiles, sometimes amounting to twenty-two in the lower jaw, and to twenty in the upper. The hind legs and feet are rounded, and have neither crests nor dentations; the interspaces of the toes are only occupied for half their extent by a short membrane. The alligators, so far as is yet known, are peculiar to the New World.

ALLITERA'TION. In Composition. The frequent recurrence of the same letter, chiefly at the commencement of different words. This is sometimes resorted to, especially in poetry, for the production of effect. In the Celtic languages, alliteration was a recognised ornament in versification: it was so likewise in the early Gothic tongues; and in old English there are entire poems composed in alliterative metre, of which the celebrated Vision of Piers Ploughman is the most remarkable.

ALLOCA'TION. In Law. The allowance of an account in the Exchequer. The writ *de allocatione facienda* is for allowing an accountant sums expended by him in his office. The certificate of allowance of costs of taxation granted by the master, prothonotary, or other officer of court, is termed in practice an *allocatur*.

ALLO'CHROITE. A massive mineral allied to the garnet. Melted with phosphate of soda before the blowpipe, it exhibits several changes of colour, hence its name, from ἀλλος, *another*, and χροια, *colour*.

ALLO'DIUM. In feudal Law. A word of uncertain derivation (deduced by some writers from the old Teutonic "aloud," denoting the antiquity of the tenure). Land held by an individual in his own absolute right, discharged of all feudal obligation: opposed, therefore, to fee, fief, or feud. No allodial property can exist in England, where the king, in the eye of the law, is lord paramount of all lands and hereditaments. In ancient France the rule was, "nulle terre sans seigneur," and the presumption was in some parts of that country always in favour of a fief, unless the land were shown to be allodial. In Germany, on the contrary, the legal presumption was in favour of the allodium.

ALLO'TMENT OF LANDS. Any piece of land, set apart or allotted for any particular purpose. When more land is laid to a cottage than suffices for a garden, it is commonly called a cottage allotment.

ALLOY', or ALLAY. (From the French verb alloyer, *to mix one metal with another, in order to coinage;* derived perhaps from *à la loi*, the proportions of the metals being regulated by law; perhaps from allier, *to unite;* or allocare, *to put together*.) A term applied to compounds of the precious metals with others of less value, or to the least valuable of the metals in such compounds: thus, gold is said to be alloyed with silver, and silver with copper. Chemists generally apply the term to all combinations obtained by fusing metals with each other: thus, brass is an alloy of copper and zinc; and bronze, of copper and tin; except when mercury is one of the combining metals, in which case they call the compound an amalgam. Many of the alloys are importantly useful in the arts: thus, gold and silver, which in their pure state are too soft and flexible for the manufacture of plate, coin, trinkets, &c., are hardened by the addition of a certain portion of copper; while their colour and other valuable qualities are not materially impaired. The standard gold in circulation in this country, is an alloy of 11 parts of pure gold, and one of copper. Sometimes the alloy consists partly of silver, especially in the older coins; and it is to the preponderance of one or other of these alloys that the different colour of gold coin is owing; the paler containing silver, the deeper coloured, copper. A little palladium is sometimes present, which gives the gold a disagreeable brownish hue, as seen occasionally in some sovereigns. Our standard silver, used for coin, consists in 12 parts, of $11\frac{2}{20}$ silver, and $\frac{18}{20}$ copper: in these alloys it is necessary to employ copper of the utmost purity; for a very minute portion of some of the other metals, especially of lead, renders the precious metal brittle. The silver alloy used for plate is the same as that for coin, and the purity is guaranteed by the stamp of the Goldsmiths' Company. The subject of alloy for coin underwent an elaborate investigation at the beginning of the present century by order of government; the inquiry was intrusted to Mr. Cavendish and Mr. Hatchett, and the latter gentleman has published a valuable account of his experiments in the "Philosophical Transactions" for 1803, to which the reader is referred.

Some curious circumstances ensue in the combination of metals, as affecting their densities; the specific gravity of an alloy being sometimes greater and sometimes less than the mean of its components,—showing that in some cases expansion has taken place, and in others contraction.

Alloys generally melt at a lower temperature than that required for the fusion of their component metals separately; and in some cases the most refractory metals form very fusible alloys. There are some alloys which are crystallisable, and probably of definite composition; but the atomic doctrine applies only in a few cases to the alloys, and it is often difficult to get a mass of alloy of similar composition throughout; thus, gold made standard with copper, and then cast into bars in upright moulds, does not yield an uniform compound except under due precautions; for the upper end of the bar, containing the metal from the bottom of the crucible, will be the purest.

A'LLSPICE. The dried immature berry of the Myrtus Pimenta; called also Jamaica Pepper. It is supposed to possess the mixed flavour of several spices, amongst which that of the clove predominates.

ALLU'SION, in Rhetoric. (Lat. ad, *to*, and ludo, *I*

play.) Strictly, a covert indication, as by means of a metaphor, a play of words, &c. of something not openly mentioned and extrinsic to the principal meaning of the sentence. In common language, to allude to any thing merely means to mention it indirectly or incidentally.

ALLU'VIUM. (Lat. alluo, *I wash upon.*) Gravel, sand, and other transported matter washed down by rivers and floods, upon land not permanently submerged beneath water.

ALMACA'NTAR. (From the Arabic.) A term used by the old astronomers to denote a small circle of the sphere parallel to the horizon.

ALMAGE'ST. A name given by the Arabs to the celebrated work of Ptolemy, the astronomer of Alexandria: it signifies the greatest work. The best edition of this work is that of Paris, 1813-15, two vols. 4to., Greek and French, by M. Halma.

A'LMANACK. (Probably from the Arabic particle *al* and manach, *to commit;* whence Al Manach, *The Diary.*) An annual publication containing a calendar of the days and months of the year, the ecclesiastical feasts, the time of the sun's rising and setting, the age of the moon, the solar and lunar eclipses. To these (the most essential matters) are frequently added information on various subjects of astronomy, chronology, meteorology, the tides, statistics, lists of posts, offices, public institutions, &c., according to the views or fancy of their respective authors. Almanacks correspond in some respects to the Fasti of the Romans, and are of very ancient date. The first printed almanack appeared in 1474, and was drawn up by Regiomontanus, nearly, at least so far as regards the calendar, in the form now used. Till within a few years, the numerous almanacks published in England were little creditable to the taste or morals of the country. They had for a long time been monopolised by the Stationers' Company. This monopoly was at length broken through by the publication of a new almanack under the superintendence of the Society for the diffusion of Useful Knowledge; and since that time the more exceptionable ones have entirely disappeared, and their place been supplied by others which abound in useful and valuable information. The removal of the heavy stamp duty of fifteen pence per copy, to which they were subjected till 1834, has been attended with all the advantages which usually result from the exercise of free competition.

The Nautical Almanack is published by order of the board of the admiralty for the use of seamen, and contains a copious list of astronomical phenomena at sea, and of the elements which are used in finding the longitude. This work is also a very complete astronomical ephemeris, showing the instants of time at which the planets and principal stars daily pass the meridian of Greenwich; the sun's right ascension, and the logarithms of his distances; the moon's place at intervals of three hours, &c. &c. For a more particular account of works of this kind, *see* CALENDAR, EPHEMERIS.

A'LMOND. (Gr. ἀμυγδαλον. Fr. amande.) The seed or kernel of the Amygdalus communis. Sweet almonds afford, in the 100 parts, 54 of fixed oil, 24 of albuminous matter, 9 gum and sugar, 4 woody fibre, 5 husk, and 4 water and loss. Bitter almonds contain less fixed oil, and a peculiar principle termed *Amygdalin.* When bitter almonds are cold pressed, the oil which exudes contains no trace of prussic acid; when hot pressed, its flavour may be perceived: the cake remaining after pressure yields a volatile oil by distillation, the quantity and strength of which in prussic acid is variable. The oil of bitter almonds is about the specific gravity of water; that which passes first over is most poisonous. It changes when exposed to air, and forms benzoic acid: in close vessels it may be long kept without deterioration. When used in medicine, great care is requisite on account of its varying strength. Half an ounce of oil of bitter almonds was put into the mouth of a Newfoundland dog (in a diseased state and moaning with pain), with the intention of immediately killing it; but after some slight convulsions the animal became tranquil, appeared easier, and recovered the effect: about a drachm of recently and carefully prepared oil was then administered, when the animal fell upon its side, became convulsed, and died in three minutes. The distilled oil of peach leaves and of the cherry laurel also contain prussic acid, and the water distilled from them is poisonous. By digesting these oils with finely powdered peroxide of mercury, crystals of cyanuret of mercury are formed.

A'LMONER. An officer in a religious house, to whom the distribution of alms was committed. The term is still retained by officers in some of our hospitals.

ALMS. Charitable offerings; from the Greek ἐλεημοσυνη, *pity;* which came in the early ages of the church to be used in the plural number in the peculiar sense which is represented in our language by the word Alms.

A'LOE. (Arabic, alloch.) A small tree with endogenous stems, and stiff, fleshy, hard pointed leaves, abounding in a purgative principle which is obtained by simple pressure of the bruised leaves, or by boiling. The juice when inspissated becomes the medicinal drug of the shops. It varies much in quality. (See the following article.)

A'LOES. The inspissated juice or extract of several species of aloe. This article is largely imported for medical use from Bombay. It is of a brown colour, a peculiar and somewhat aromatic odour, and a nauseous and intensely bitter flavour: it consists of extractive and resin, and is nearly soluble in boiling water, but the solution as it cools deposits flakes of resin. The best aloes was formerly brought from the island of Socotorah, in the Indian Sea, and hence all the finer aloes of commerce is frequently termed Socotorine aloes. Another variety of this drug comes from Barbadoes, in large gourd-shells containing upwards of half a hundred weight each; it is deep coloured, opaque, and has a nauseous and peculiar odour, especially when breathed upon. Aloes is a warm stimulating purgative, operating as such in the dose of four to eight grains. It stimulates the large intestines, and should be administered with caution in habits where there is tendency to piles, and in cases in females in which uterine stimulants are improper.

ALO'NSINE, or ALPHONSINE TABLES. An astronomical work, which appeared in the year 1252, under the patronage of Alonso X., in the first year of his reign.

ALO'PECU'RUS. (Gr. ἀλωπηξ, *a fox*, and οὐρα, *a tail.*) A genus of grasses, called by the farmer *foxtail;* the flowers are arranged in compact tail-like stalks. It is very like Phleum or *catstail*, from which it differs in its glumes being acute, not truncate, and its lower pales awned. *Alopecurus pratensis* forms a part of all the richest pastures in this country.

ALO'SA. The name of a genus of Clupeoid fishes, including the alose, or shad; separated from the herring and pilchard, with which it was classed by Linnæus. The shad ascends large rivers to the fresh water, where it spawns. The white-bait used to be regarded as the young of the shad, but is now ascertained to be a distinct species of the present genus.

A'LPHABET. (From the Gr. ἀλφα, βῆτα, the two first Greek letters.) The letters of a written language, disposed in their regular order. An alphabetical language is one possessing an alphabet.

1. The first and most obvious mode by which thought can be expressed and conveyed to the eye, is by the representation of actual objects. Hence the species of writing which the learned have termed *ideographic*, i. e. in which knowledge is conveyed, first, by representations of the objects of thought; secondly, by symbols. The origin of designing is coeval with that of mankind; and men early availed themselves of this art to make their thoughts visible. To make it be understood, for example, that one man had killed another, they drew the figure of a dead man stretched on the ground, and of another standing by him upright, with some deadly weapon in his hand. To let it be known that some one had arrived by sea, they drew the figure of a man disembarking from a ship; and so on. This kind of writing, if we may so employ the word, was very early used in Egypt, and most probably, also, in most of the ancient nations. In Greek, the word γραφειν signifies indifferently either to write or to paint. In Mexico, when the Spaniards landed, the inhabitants of the sea coast conveyed intelligence of the event to Montezuma by sending him a large cloth, on which they carefully painted what they had seen. It is unnecessary to insist on the difficulty and inconvenience of this method of writing; and to lessen these, recourse was had to the *symbolic* or *emblematic* variety of ideographic writing. In this method abbreviations or characteristic parts were introduced instead of the entire object. Thus, the ancient Egyptians are said to have represented a siege by a scaling-ladder; a battle, by two hands holding a buckler and a bow, &c. Abstract ideas were, also, represented by symbols, or sensible objects, supposed to have a certain analogy to them: as, ingratitude by a viper, providence by an eye, the head of a hawk, &c.

2. From ideographic was derived syllabic writing. It must have been early remarked that the sounds formed by the voice in speaking are articulate and well-defined; and the idea occurred of endeavouring to represent such sounds by appropriate signs. Thus the word *republic*, in the writing of which we use eight letters, would be written with three syllabic characters. The President de Goguet suspects that originally all the Asiatic nations, known to the ancients under the names of Syrians and Assyrians, used the syllabic mode of writing. We may, he thinks, discern the vestiges of this in an ancient tradition which ascribes the invention of writing to the Syrians; but acknowledges that the Phœnicians improved, made it more simple, and brought the characters to perfection. But this mode of writing, though a vast improvement on what is purely ideographic, is still very imperfect and cumbersome. The vast number of characters required in it overburdens the memory, and occasions the greatest confusion. The existing language of the Chinese, which is partly ideographic and partly syllabic, is an example of

this. In it there are a certain number of *elementary signs* or *keys* (two hundred and fourteen), which are strictly hieroglyphic or symbolical; that is, they are abridged representations of visible objects. From these 214 elements, all the characters of the language (80,000, it is said) are formed by varying and combining their figures; every compound character representing one or more syllables having a distinct meaning. 3. The defects incident to ideographic and syllabic writing being thus obvious, ingenious individuals would early endeavour to find out some more simple and precise method of communicating their ideas. And at length the method of Alphabetic writing, the greatest of all the inventions made by man, and which has been the great instrument of his civilisation, was introduced and perfected. In this method syllables are decomposed into their elements; and the few simple sounds emitted by the voice being represented each by its appropriate mark or letter, syllables and words are formed by their combination; the latter serving not only to describe external objects, but to depict the workings of the mind, and every shade and variety of thought. Before entering into the much disputed question respecting the origin of this mode of writing, it is necessary to indicate the new light thrown upon the subject by the recent discoveries of Dr. Young, and more especially of M. Champollion, as to the phonetic writing of the Egyptians. We have already seen that the hieroglyphical characters of that people denoted, in the first place, *objects* either of sense or thought; i. e. they were ideographic. But, according to the new theory, they came in the course of time to denote sounds; and those not syllabic merely, but alphabetical. For example, the Egyptian word Ahom signified an eagle; the figure of an eagle, therefore, stood for the letter A, with which that word begins. B was represented by a censer (Berbe). R sometimes by a mouth (Ro), sometimes by a tear (Rimé). According to the views of these recent discoverers, a great proportion of the inscriptions on Egyptian monuments and papyri are partly ideographic, partly alphabetical; i. e. some characters represent objects or ideas; and these are intermingled with others which merely stand for letters. Dr. Young, who first conceived the notion of the phonetic alphabet, imagined that it was only employed when foreign words or names (as those of Greek kings) were introduced. M. Champollion carried the discovery further, and applied it to the deciphering of words and names in the language of the country. The name of the ancient king Sabaco, among others, being found by this mode of interpretation, would appear to show that the phonetic writing was used as early as 700 years B. C. (See Dr. Young's writings, especially the article EGYPT in the Appendix to the *Encyclopædia Britannica*; those of Champollion; M. Klaproth's *Examen Critique des Travaux de Champollion*; *Quarterly Review*, vol. liii. p. 110.; Salt's *Essay on the Phonetic System of Hieroglyphics*, 8vo. London, 1825, &c.) It is not within our present province to discuss the question, upon what ground of probability this theory rests. But if a complete phonetic alphabet should be discovered, in the language of that country in which the earliest germs of knowledge and civilisation seem to have been developed, it is probable that we shall have made a considerable step towards tracing the origin of pure alphabetical writing in other languages. As it is, although various attempts have been made to show the symbolical origin of the letters in the most ancient alphabets, it cannot be said that any very satisfactory result has been obtained. And, from the total want of all recorded knowledge concerning the invention of alphabetical writing, and the difficulty of accounting for it on any known principle of mental association, the hypothesis of divine revelation has obtained considerable currency; but it need hardly be observed, how ill such a doctrine agrees with all that we know by analogy of the dealings of Providence with man.

It is clear that writing was known to the Hebrews at the period when the Mosaic books were composed, from many allusions contained in them. Exodus, xxxii. 15, 16. Numbers, xvii. 18., xxxi. 9. 19., xxxiii. 1., &c. And although it cannot be positively asserted, that the writing there alluded to may not have been of the symbolical description in use among the Egyptians, there seems, on the other hand, little reason for supposing that the Hebrew alphabet was not in use even at that remote period. And the question of superior antiquity seems to lie entirely between that alphabet and the Phœnician. The claims of the latter are supported by Mr. Astle (*Essay on the Origin of Writing*, 4to. London, 1803); but apparently on little better authority than what may be derived from the traditions of the Greeks respecting Cadmus and his alphabet; and the extreme antiquity of Hebrew civilisation and literature seems to give probability to the supposition, that the Phœnician alphabet may have been derived from theirs. The belief, however, was all but universal among the Greeks and Romans, that the Phœnicians were the inventors of letters According to Lucan,

> "Phœnices primi (famæ si credimus) ausi
> Mansuram rudibus vocem signare figuris."

And Pliny says (lib. v. cap. 12.), "Ipsa gens Phœnicum in gloria magna est literarum inventionis." But whether the Phœnicians were or were not the inventors of alphabetic writing, there can be little or no doubt that the knowledge of it was brought by Cadmus, from Phœnicia, into Greece, about 1500 years B. C. From the Phœnician, therefore, or the Hebrew, are incontestably derived, 1. The Oriental alphabets used in Asia, West of the Indus; written, like Hebrew, from right to left; the principal being the Syriac, Arabic, and Persian. 2. The Pelasgic, or original Greek alphabet. Were there nothing else by which to establish the fact, the eastern origin of the Pelasgic language would be obvious from its being originally written, like the Phœnician and other eastern languages, from right to left. It was afterwards written consecutively from right to left, and left to right, in the manner that land is ploughed. This procured for it the name of *βουστροφηδὸν*, or furrowed writing. This species of writing maintained its ground for a lengthened period. The laws of Solon, promulgated about 594 years B. C., were written in it; and it was used till the 5th century B. C. But writing from left to right was introduced for a considerable period before the alternate or furrowed method was abandoned. Inscriptions dated 742 years B. C. have been found written from left to right, or in the way now practised. (Goguet, *Origin of Laws*, Eng. trans. ii. p. 32. &c.) From the Pelasgic alphabet were derived the Etruscan and Oscan. From the Ionic, a later variety of the Greek, came the Arcadian, the Coptic, and Ethiopic, the Mæso-Gothic and Runic; and, in comparatively modern times, the Armenian, Illyrian, Sclavonic, Bulgarian, and Russian. With regard to Greek writing, it is to be observed that the most ancient mode was in capitals. The small letters now in use seem to have been introduced gradually; for, in our oldest Greek MSS., even as early as the fifth century, they appear intermixed with capitals. But the latter were principally employed, until the seventh or eighth century. 3. The Latin alphabet is also derived from the Ionic Greek; it is said to have been introduced about the time of Tarquinius Priscus. In the earliest inscriptions which we possess, the forms of the letters scarcely differ from those in use at the present day; but, great varieties have been in subsequent times introduced: first, in the ordinary method of writing it; as, the Uncial, Semi-Uncial, Lombard, Italic, &c. (*See* CHARACTER.) Secondly, in the number and form of the letters contained in the numerous alphabets derived from it. 4. A fourth class of alphabetical languages consists of the Sanscrit and its derivatives. These are very numerous, and are spoken in the continent and islands of India. The antiquity of the Sanscrit alphabet is undoubtedly great; but those who assign to it a separate origin are probably in error. Its derivation from the Hebrew, or some of its cognate alphabets, admits of little doubt. Indeed, the great regularity of the Devanagaree, or most elegant form of the Sanscrit alphabet, and its copiousness (it contains 100 letters), seem to afford strong presumption that it was compiled by some learned individual, or body, (like the Russian and other modern Western alphabets,) from other forms of writing then in use, and imported into India from the West. The Sanscrit and its derivative languages are written, like European, from left to right. These four classes comprehend all the alphabetical languages in existence. The following table exhibits the number of letters in some of the principal.

- Class 1. Hebrew, Samaritan, Syriac, and Chaldean, 22 each. Phœnician (known), 17. Arabic, 28. Persian, 32.
- Class 2. Greek, 24. Armenian, 38. Ethiopic, or Abyssinian, 202. Modern Russian, 41.
- Class 3. (which is only a subdivision of Class 2.) Latin, 22. English, 26. French, 28. Italian, 20. German, 26.
- Class 4. Sanscrit (Devanagaree), 100.

Various learned persons have proposed the adoption of an universal alphabet; and have shown that the elementary sounds are reducible to a still smaller number than those employed in our western alphabets. Harris (*Hermes*, book iii. c. 2.) estimates them at twenty. Wachter (*Naturæ et Scripturæ Concordia*) conceives that the number may be diminished to ten. But the celebrated Bishop Wilkins, in his *Essay towards a real Character and Philosophical Language*, fol., London, 1668, estimates the necessary number at thirty-four.

The following Table contains specimens of the principal alphabets.

ALPHO'NSIN. An instrument for extracting balls: so called from the name of its inventor, Alphonso Ferrim, a Neapolitan surgeon.

A'LPINE PLANTS. Low plants which grow naturally in hilly or mountainous situations, where they are covered with snow during great part of the winter; and for which reason, in gardens, they require the protection of frames and glass during winter. In this respect alpine plants differ from rock plants; which, in gardens, only require to be grown among rocks or stones, without the protection of a frame and glass.

ALPINIA'CEÆ. One of the names of the natural order of plants called Zingiberaceæ.

ALRU'NÆ. (Germ. Alraun, Alraun-bilder.) Small images carved out of the roots of trees, exhibiting rude representations of the human figure, generally female. The veneration paid to these figures formed a peculiar feature in the superstition of the northern nations. They were looked on as the Penates, or household gods, of families; laid in boxes, and presented with meat and drink. They are supposed by some to represent female magicians or druidesses.

ALSEGNO. (It. *To the mark.*) In Music, a notice to the performer that he must recommence from that part of the movement to which the sign or mark 𝄋 is prefixed.

ALSINA'CEÆ. A rather extensive order of weedy plants, allied to the much more beautiful Silenaceæ, from which they are known by their calyx consisting of distinct sepals. The order derives its name from Alsine (aloos, *a sacred gem*, in which places it is found), the common chickweed.

ALT. (Lat. altus, *high.*) In Music. A term applied to the high notes of the scale.

A'LTAR. (From alta ara, Lat.; or, according to some, from אל, *God*, and ראה, *described*, or *appointed.*) In Architecture, a sort of pedestal whereon sacrifice was offered. Servius tells us that among the ancients there was a difference between the ara and altare, the latter being raised on a substruction, and used in the service only of the celestial and superior divinities, whilst the former was merely on the ground, and appropriated to the service of the terrestrial gods. To the infernal gods the altars were made by excavations, which were termed scrobiculi. Some authors have maintained that the ara was the altar before which prayers were uttered, whilst the altare was used for sacrifices. It does not, however, appear that ancient authors made these distinctions, but that the words were used by them indiscriminately. The earliest altars were square polished stones, on which were placed the offerings to the gods. Whilst sacrifices were confined to libations, perfumes, and offerings of that sort, the altar was not of large dimensions, and was even portable; but as soon as man thought he was doing honour to the Divinity by an offering of blood, the altar necessarily expanded in dimensions. Different forms were contrived, according to the nature of the sacrifice, on which the throat of the victim was cut and the flesh burnt. Of this sort is the circular altar of the villa Pamphili at Rome, one of the largest and most elegant of existing remains of that class. Upon it is to be seen the cavity for holding the fire, and the grooves for carrying off the blood. The varieties of altars follow the service to which they were assigned by difference in their forms, ornaments, and situations. Some, as we have already observed, served for burning incense and receiving libations. Some were for the sacrifices of blood, and others for receiving offerings and sacred vases. Many were erected merely as monuments of the piety of the devotee, whilst others were constructed to perpetuate some great event. They served for adjuration, as well as for an asylum to the unfortunate and evil-doer. The forms varied from square to oblong, from triangular to circular. Those of metal were usually tripodial. When of brick or stone, they were generally square on the plan. According to Pausanias, wood was occasionally a material of which they were composed. They do not seem to have been of any standard height, inasmuch as we sometimes see them on bassi relievi reaching little above a man's knee, whilst in others they appear to reach his middle, though it would seem that the circular altar was generally the highest in proportion to its diameter. Vitruvius says they should be kept down in height, so that they may not intercept the statues of the gods; and he gives the relative height of those used for the different divinities. Those of Jupiter and the celestial gods the highest; next, those of Vesta and the terrestrial gods; then the sea gods were to have theirs a little lower, and so on. On festivals they were decorated for the occasion with such flowers and leaves as were sacred to the particular divinity. But besides this casual decoration, the ancient altars furnish us with some of the most elegant bassi relievi and foliage ornaments that are extant, still serving as models of taste, which have escaped the hands of the barbarian destroyer. According to Vitruvius, their fronts were turned towards the east, though often little regard seems to have been paid to their position, as they were occasionally deposited under the peristyle of a temple, and not unfrequently in the open air. In the larger temples there were often three different altars: the first was in the most sacred part, in front of the statue of the god; the second was before the door of the temple; and the third was portable, called anclabris, on which the offerings and sacred vases were placed. Amongst Christians, the altar is a square or oblong table or tablet, placed at the east end of the church, for the celebration of the mass, or, in Protestant churches, for the celebration of the sacrament. These are varied in their form almost as much as those we have already described.

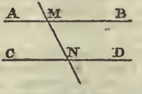
The word *Altar* was adopted by the early Christians, together with the corresponding Greek term θυσιαστηριον, (but not, unless, perhaps, in a single instance, βωμος,) to express the table of the Lord (1 Cor. x. 21.). But the word altar is stated to have been used by the fathers in four different senses (v. Suicer, in voc. θυσιαστηριον): for, 1. Christ himself, from Hebr. xiii. 10. 2. The church of Christ in general. 3. Individual members of the church. 4. The Lord's table. It is observed that the fathers of the first three centuries universally speak of the altar, and not of the table, although constantly admitting the charge which the heathens made against them of their having no altars, conceiving the term as used by the heathens to imply the offering of a sacrifice upon the altar, and the presence of the statue of the deity to whom the offering is made. From the fourth century the word table is frequently adopted, as by St. Chrysostom, St. Augustin, &c.

In King Edward I.'s Book of Common Prayer, the word altar was retained in the communion service: but great opposition being raised against it, especially by Bishop Hooper, on account of the ambiguity of its meaning, and the colour it might seem to lend to the Romish notions of the eucharist, it was abandoned, and table substituted throughout. This, however, did not satisfy the more violent party; and on the restoration of the reformed worship at the accession of Elizabeth, the people proceeded to take the first step towards a real and not a verbal substitution, by pulling down the altars in many churches. Hereupon the queen issued an injunction, wherein she declares that "it is no matter of great moment whether there be altars or tables, so that the sacrament be duly and reverentially administered;" and directs that where the altars had been pulled down, tables should be erected in the same place.

A'LTERATIVES. (Lat. altero, *I change.*) Medicines which cure diseases by slow and imperceptible degrees, without producing sensible evacuations.

ALTE'RNATE. (Lat. alternatus, *changed by turns.*) In Botany, parts are said to be alternate with each other when one is placed upon the stem a little higher or a little lower than the other; the word is chiefly applied to leaves, and is used in distinction to opposite, in which parts arise from the same plant on opposite sides of the stem.

ALTERNATE. (Geometry.) When two straight lines are intersected by a third, the interior angles on the opposite sides of the intersecting line are said to be alternate. Thus A M N and M N D are alternate angles; and so also are B M N and M N C.



If the two straight lines A B and C D be parallel, the alternate angles are equal. In proportion, the alternate terms are the first and third, and also the second and fourth, and the terms of a proportion are said to be taken alternately, or by alternation, when the second and third are made to change places: and it is a well-known theorem, that a proportion subsisting among four quantities of the same kind is not disturbed by this change. Thus, if $a : b :: c : d$, then, alternately, $a : c :: b : d$.

A'LTICA. A name applied by Fabricius to a subdivision of the Linnæan Chrysomelæ, characterised by the oblong body, bifid lip, and thickened hind legs.

A'LTITUDE. (Lat. altus, *high*, altitudo, *height.*) In Astronomy, denotes the angle of elevation of a celestial object, or the angle of the visual ray with the horizon. The altitude of a star is apparent or true. The apparent altitude is the angle ascertained immediately from observation; the true altitude is found by correcting the apparent altitude for refraction, parallax, &c. Altitude is frequently used in Elementary Geometry instead of height. The altitude of a triangle is measured by a straight line drawn from the vertex perpendicular to the base; and the altitude of a cone by the straight line drawn from the vertex perpendicular to the plane of the base.

ALTO. (Lat. altus, *high.*) In Music, the counter-tenor part, or that immediately below the treble or highest. It is a word also used to denote the tenor violin.

ALTO RILIEVO. *See* RILIEVO.

A'LUDEL. A piece of chemical apparatus used in the process of sublimation, and much resembling the ancient alembic.

A'LULA. (Lat. ala, *a wing.*) In Ornithology, the group of ill-feathers, attached to the joint of the carpus; as in the snipe. These are also called the 'bastard wings' (*ala spuria*).

A'LUM. A salt composed of alumina, potash, and sulphuric acid, and in its usual form containing a large quantity of water of crystallisation. Its octohedral crystals consist of

Alumina	3 atoms	=	54	10·76
Potassa	1	=	48	9·95
Sulphuric acid	4	=	160	33·74
Water	24	=	216	45·55
Crystallised alum	1	=	478	100·00

Alum dissolves in about five parts of water at 60°. The solution has a sweet and astringent taste, and is a powerful styptic. When crystallised alum is heated, it melts, and, gradually losing water of crystallisation, becomes a white spongy mass, called burned alum.

Alum is largely manufactured for the uses of the arts, especially dying and calico printing. What is termed alum ore, is an aluminous slate containing sulphuret of iron; it is calcined, exposed to air, lixiviated, and the solution so obtained mixed with sulphate of potash, and crystallised. The alum-works near Paisley, and at Whitby, in Yorkshire, are the largest in this country.

Milk, curdled by stirring it with a lump of alum, furnishes alum whey, which is sometimes taken as a remedy for relaxed bowels. Alum curd is made by beating the white of egg with a piece of alum till it coagulates.

ALU'MINA. Aluminous earth; earth of alum; argil. When a solution of ammonia is dropped into a solution of alum, a white precipitate falls, which, thoroughly washed, dried, and heated, is pure aluminous earth. There are two properties of this earth which render it of great importance in the arts: one is, that it forms a plastic mixture with water, and, though it is not the predominant ingredient in, yet it confers the valuable property of plasticity upon, all natural clays, which enables them to be moulded into the various forms of pottery and earthenware; the other is the remarkable affinity of alumina for colouring and extractive matter, whence its use in the arts of dyeing and calico printing.

In a pure and crystalline form, alumina constitutes the sapphire, one of the hardest and most valuable of the gems. In its common state, aluminous earth is a soft white powder, strongly attractive of moisture; hence, aluminous fossils are often recognised by adhering to the tongue, and many of them exhale an earthy smell when breathed upon, as we observe in common slate. Alumina consists of 52·94 aluminum, and 47·06 oxygen; like the other earths, as they are usually called, alumina, therefore, is a metallic oxide. Aluminum is with difficulty obtained, and in small quantities, by heating chloride of aluminum with potassium; it is a grey, difficultly fusible metal, not easily acted on by water, and which, when heated in the air, burns with great brilliancy, and forms alumina by the absorption of oxygen.

Alumina has but a feeble attraction for acids, and does not fully neutralise them; and when it has been heated red hot, or is in an indurated state, as it exists in the sapphire, in corundum, and some other minerals, it is absolutely insoluble.

The aluminous salts are mostly colourless, soluble in water, and of a sweetish astringent taste. Exclusive of alum, the acetate of alumina is the most important of these salts, being used as a base or mordant by the dyers. (*See* DYEING.) It is usually prepared by mixing a solution of 190 parts of acetate of lead with one of 487 parts of alum: a white precipitate of sulphate of lead falls, and acetate of alumina remains in solution.

ALU'MINITE. Native subsulphate of alumina.

ALU'MINUM. The metallic base of alumina.

A'LUMSTONE. A silicious subsulphate of alumina.

ALU'RNUS. A genus of coleopterous insects, characterised by having short filiform antennæ; palpi four to six, very short; maxillæ horny and short.

ALUTA'CEOUS. (Lat. aluta, *tanned leather.*) A pale brown colour.

ALVE'OLAR. (Lat. alveolus, diminutive of alveus, *a cavity.*) Belonging to the alveoli, or sockets of the teeth.

ALVE'OLATE. In Botany. When the surface is covered with numerous deep hollows, as in the receptacle of some Compositæ.

ALVEO'LITES. A genus of fossil zoophytes, allied to the corallines; one species of which (*Alv. suborbicularis*) occurs in the Portland stone.

A'LVINE. (Lat. alvus, *the belly.*) A term generally used as relating to the intestinal excretions.

A'MADOU. German tinder; a fungus found chiefly in old oaks and ash trees. It is boiled in water, dried, beaten, soaked in a solution of nitre, and again dried for use.

AMA'IN. A sea term, signifying *to yield, to let go.* Thus, to strike amain is to lower or let fall the topsails, in token of surrender. To wave amain is to make a signal to a vessel to strike its topsails. Amain is also a term used in letting down a thing into the hold or elsewhere, or in lowering a yard, or the like, to denote that the sailors are to let go that part of the rope which they held before, and let down the thing easily and by degrees.

AMA'LGAM. A combination of mercury with other metals. Medallists apply the term to soft alloys generally.

AMALTHÆ'A. In Mythology. The name of a goat in Crete, alleged to have suckled Jupiter: or of the nymph who tended the goat. The *cornu Amalthææ*, or horn of the goat in question, was the magic *cornu copiæ*, or horn of plenty.

A'MARANTH. (Gr. ἀ, priv., μαραινω, *I wither,* and ἀνθος, *a flower.*) Plants with richly coloured flowers, whose parts are of a thin dry texture, so that they are a long while before they wither. They give their name to the natural order of Amaranthaceæ. Amaranthus melancholicus, hypochondriacus, caudatus, &c., are the annuals known in gardens by the names of Love lies bleeding, Prince's feather, &c. The name, in composition with other words, is used to designate plants not belonging to the same genus, but to the same natural order. Globe-amaranth is Gomphrena globosa.

AMARANTHA'CEÆ. The order which comprehends the amaranthus, and other similar dry-flowered genera. Some of the species are objects of ornament, as cockscombs (*Celosia coccinea*), globes (*Gomphrena globosa*), various species of amaranthus, trichinium, &c.; but the principal part consists of tropical kinds. The order participates in the harmless qualities of Chenopodiaceæ, from which it is not very different.

AMARYLLIDA'CEÆ. (Amaryllis, one of its genera.) A natural order of beautiful Endogens, with inferior fruit, six stamens, and six nearly equal segments of the flower. The greater part consists of bulbous species inhabiting the Cape of Good Hope, and the tropical parts of both hemispheres. Snowdrops are the most northern form. A few, such as agave and doryanthes, are trees in stature, although only herbaceous plants in duration.

A'MATEUR. (Fr.) A person familiar with, and who encourages any particular art or pursuit, without being professionally engaged in it, is said to be an amateur. But the term is usually restricted to those who are skilled in and patronize the fine arts.

AMAURO'SIS. (Gr. ἀμαυρος, *dark.*) A loss of sight dependent upon defective action of the nerve of vision, and independent of visible injury. It is also called gutta serena: drop serene of Milton.

AMAZO'NIAN STONE. A beautiful green felspar, found in rolled masses near the Amazon river.

A'MAZONS. (Gr. ἀ, *without,* and μαζος, *breast.*) Female warriors. Tribes, either real or imaginary, belonging to Africa and Asia, among which the custom prevailed for the females to go to war; preparing themselves for that purpose by destroying the right breast, in order to use the bow with greater ease. According to Greek tradition, an Amazon tribe invaded Africa, and was repulsed by Theseus, who afterwards married their queen. Hence, all female warriors have been called Amazons; and the river of that name owes its appellation to one of the early Spanish navigators, who fancied he beheld armed women on its banks. The wars of the Athenians and Amazons formed favourite subjects for Attic art: they were depicted in the Pœcile or painted chamber of the Parthenon. See Justin, Diod. Siculus, Strabo, &c.

AMBARVA'LIA. (Lat. ambire arva, *to go round the fields.*) In Roman Mythology, religious fêtes to propitiate Ceres; so called from the victims being carried round the fields (*ter circum ibat hostia fruges,* Virg. G. i. 345.). These sacred rites were performed by an order of priests, *Fratres Ambarvales,* twelve in number. They were celebrated in the end of May, when the blessing of the goddess was invoked on the coming harvest. The victims were accompanied by crowds of country people, having their temples bound with oak leaves, dancing, and singing the praises of Ceres, to whom libations were made of honey and wine. (*Facciolati; Adam's Antiq.*)

AMBA'SSADOR, or EMBASSADOR. In Politics, the name of the highest order of foreign ministers. An ambassador is not only the agent of the country which sends him, but also represents personally the dignity of its sovereign. The greater powers of Europe send ambassadors to each other, with the exception of Prussia, which never employs ministers of this class. The word ambassador is of very uncertain derivation, but is supposed to be derived from the Italian word ambasciare, *to solicit.* In charters and diplomas of later date than the ninth century, the names of those who had solicited the grants are frequently signed at the foot with the designation of "ambasciatores," or solicitors; and it may hence be presumed that the title was originally given to envoys who attended at a court to solicit some favour for another party. As to the rights and privileges of ambas-

sadors in England; if an ambassador commit any act which is a crime against the law of all countries, as treason, felony, &c., he is punishable as a private alien. But an ambassador is not criminally liable for such acts as are only mala prohibita against statute or custom; as, infringements of the laws of the exchequer. By 7 Anne, c. 12., an ambassador or public minister, and his domestic servants, *bonâ fide* registered according to the act, are privileged from arrest; and the goods of an ambassador cannot be taken in distress. This statute was passed in consequence of the arrest and ill treatment of Count Matuschef, the Russian ambassador. As to the rights and duties of ambassadors in modern international usages, see the elaborate work of M. de Wicquefort, *L'Ambassadeur et ses Fonctions*, 2 tomes, 4to, 1746; F. von Moshamon (*Law of European Embassies*, Landshut, 1806); and the valuable *Manuel Diplomatique* of Von Martens (Leipzig, 1822), may also be consulted.

A'MBER. A yellow resin-like substance, found occasionally in detached pieces on the sea-coast, but most generally dug up in diluvial soils: it is probably an antediluvial resin, and often contains leaves and insects. Its specific gravity is about 1070. It is hard, and becomes strongly electro-negative by friction. It contains a trace of odorous volatile oil, a resin easily soluble in alcohol, a resin difficultly soluble in alcohol, and an insoluble resin, which is its chief constituent (80 to 90 per cent.). When burned, it exhales a fragrant odour. Distilled per se, it yields inflammable gases, water holding succinic and acetic acids, and empyreumatic oil in solution (the spirit of amber of old Pharmacy), sublimed succinic acid (salt of amber), and an empyreumatic oil (oil of amber). The acid, when purified, amounts to from 3 to 5 per cent. The residual charcoal amounts to 12 or 13 per cent., and, when strongly heated, yields a little volatile matter resembling camphor.

A substance resembling amber, called fossil copal, sometimes occurs with it; it is less soluble in alcohol, and yields no succinic acid.

The largest known mass of amber was found near the surface of the ground in Lithuania, about twelve miles from the Baltic; it weighs eighteen pounds, and is in the royal cabinet at Berlin.

The chief use of amber is as an article of ornament, cut into beads for necklaces, and in the manufacture of varnish.

A'MBERGRIS. (From ambre, and gris, *grey amber.*) This substance has been found in the intestines of the spermaceti whale: it is probably a product of disease; perhaps a kind of gallstone. It has also been found upon the coasts of various tropical countries, in masses of various sizes, of a grey, speckled appearance, and interspersed throughout its substance with the beaks of the sepia octopoda, which is the common food of the whale. When genuine, ambergris has a peculiar odour, not easily described or imitated, and which is exceedingly diffusive, especially in solution, so that a very minute quantity of ambergris is perceptible in perfumes, and is thought to exalt their odour. A grain or two, when rubbed down with sugar, and added to a hogshead of claret, is very perceptible in the wine and gives it a flavour, by some considered as an improvement. The best ambergris is softish and somewhat waxy when cut; its specific gravity varies from 780 to 896: it fuses at 140° or 150°, and at a higher temperature gives out a white smoke, which condenses into a crystalline fatty matter. Its chief component (about 80 per cent.) is a peculiar fatty matter (ambreine), which may be obtained by boiling it in alcohol; as the solution cools, it deposits crystals, which may be purified by pressure in folds of blotting paper. Ambreine fuses at 100°; its odour is agreeable, and it rises in vapour at 220°.

AMBIDE'XTER. (Lat. ambo, *both*, and dexter, *right hand.*) One who uses both hands alike, the left as well as the right. Numerous theories have been advanced to explain the preference so generally given to the right over the left hand; but, generally, they seem to be more specious than solid.

A'MBITUS. (Lat. ambio, *I encompass*, or *circumvent.*) The circumference or extreme edge of any thing; the encompassing border of a leaf.

Ambitus. n Politics. A term used by the ancient Romans to designate the soliciting and canvassing for offices and honours. It was of two kinds, the one, *ambitus popularis*, laudable; as, where a candidate openly avowed his pretensions, publicly stated the grounds on which he solicited the suffrages of the electors, and left them to form their opinion upon his claims without privately soliciting their votes. The other, and more common kind of *ambitus*, was either disreputable or unlawful. It consisted in using artful solicitations, cajolery, offers of money and preferment, and all those resources for corrupting the free choice of electors, so well understood, and successfully practised, in our own times. The bribery of electors was forbidden, although to very little purpose, by repeated acts of the Roman legislature. (Facciolati *Lexicon*, Adam's *Antiquities*, &c.)

A'MBLE, AMBLING. (In Horsemanship, Terme du Manège.) A peculiar kind of a pace in which a horse's two legs of the same side move at the same time.

AMBLO'TIS. (Gr. ἀμβλωσις, *abortion.*) The generic name, in the system of Illiger, of the Marsupial genus, including the wombat.

AMBLYO'PIA. (Gr. ἀμβλυς, *dull*, and ὢψ, *the sight.*) Imperfect vision.

AMBLY'PTERUS. (Gr. ἀμβλυς, *obtuse*, and πτερον, *a fin.*) The name of a fossil genus of fishes, with obtuse and rounded pectoral and ventral fins, and characterised by having small and numerous teeth, set close together like a brush, which shows the habit of these fishes to have been to feed on decayed sea-weed and soft animal substances at the bottom of the water.

A'MBO. (Gr. ἀμβον, *a boss*, or *knob.*) In Architecture. The elevated place, or pulpit, in the early Christian churches, from whence it was usual to address the congregation, and on which certain parts of the service were chanted.

A'MBREIN. The fatty matter of ambergris; convertible by nitric acid into ambreic acid.

AMBRO'SIA. (Gr. signifying, *immortal.*) The food of the gods, as nectar was their drink, the use of which conferred immortality.

AMBROSIAN CHANT. In Music. So called from St. Ambrose, archbishop of Milan, who composed it for the church there in the fourth century: it is distinguished from the Gregorian chant by a great monotony and want of beauty in its melody.

A'MBUBAIÆ. A Syrian or Arabic term, meaning musical girls from Syria, who prostituted themselves at Rome. See Hor. *Sat.* lib. 1. sat. 2. v. 1. and Facciolati *Lexicon.*

AMBULA'CRA. (Lat. ambulacrum, *an alley.*) The narrow longitudinal portions of the shell of the sea-urchin (*Echinus*), which are perforated with a number of small orifices, giving passage to tentacular suckers, and alternate with the broad tuberculate spine-bearing portions.

AMBULATO'RES. (Lat. ambulo, *I walk.*) The name of an order of birds in the system of Illiger, corresponding nearly with the *Passeres* of Linnæus.

A'MBULATORY. Formed for walking. In Ornithology, the term is applied to the feet of birds where the toes are placed three before and one behind.

AMBU'SCADE. A military term derived from the Italian imboscata, concealed in a wood. It is also applied to any snare laid for an enemy.

AMBU'STION. (Lat. amburo, *I burn.*) A medical term for a burn or scald.

A'MEN. (Heb. אמן, signifying, *let it be*, or rather, *let it be irrevocably fixed.*) It is understood to express belief and assent at the end of a prayer. It is sometimes translated, verily, as when used at the beginning of a discourse.

AME'NDE HONORABLE. In French Law, a species of infamous punishment, to which criminals guilty of an offence against public decency or morality were condemned under the ancient system, and are so still in some instances. Such were, sedition, forgery, sacrilege, fraudulent bankruptcy, &c. The *simple* or *dry* amende honorable consisted merely of an acknowledgment by the criminal of his offence in open court, bare-headed and kneeling. The *amende honorable in figuris* was made by an offender, kneeling in his shirt, a torch in the hand, a rope round the neck, and conducted by the executioner. It was, and still is, usually conjoined with some other punishment; sometimes capital, as in the case of parricides, &c.

AME'NDMENT. In a general sense, is any change made in any thing for the better. In Parliamentary Proceedings, it is an alteration in the words of any bill or motion, which it is competent for any member to move when the bill or motion has been read. (*See* Parliament.)

Amendment. In Law. The correction of an error committed in any process: as the amendment of a declaration, plea, &c. The deficiency of means of amendment in pleading at common law, led to the statutes of amendments and jeofails, beginning with that of 14 E. 3. All amendments are held to be within the discretion of the court, and allowed in furtherance of justice according to the particular circumstances of each case.

AME'NORRHŒA. (Gr. ἀ, *without*, μην, *a month*, and ῥέω, *I flow.*) Morbid irregularity or deficiency of the menstrual discharge.

AMENTA'CEOUS. Having amenta; a name formerly applied in Systematic Botany to such plants as have their flowers arranged in amenta. But as very different kinds of structure were combined by this character, the order Amentaceæ of Jussieu is broken up in several others, and the term is but little used.

AME'NTHES. in Eastern Mythology. the kingdom of the dead, or Tartarus of the ancient Egyptians.

AMENTIA. (Lat. amens, *deprived of mind.*) Idiotism.

AME'NTUM. (Lat. amentum, *a thong*, or *loop.*) A kind of inflorescence such as is found on willows and poplars: it differs from a spike only in being deciduous.

AME′RCIAMENT. (From the French *merci.*) The pecuniary punishment of an offender against the king or other lord in his court, when by his offence he is said to stand at the mercy of the king or lord.

AMETABO′LIANS, AMETABOLIA. (Gr. ἀ, *without*, and μεταβολη, *change.*) A sub-class of insects which do not undergo any metamorphosis.

A′METHYST. Purple rock crystal. The finer varieties are in great request for cutting into seals and brooch stones. Some of the ancient vases and cups are composed of this mineral, and it was an opinion among the Persians that wine drank out of an amethystine cup would not intoxicate: hence its name, from the Greek ἀμεθυστος.

A′MIA. The name of a Linnæan genus of abdominal fishes founded on a single species (*Amia calva*, Linn.) a native of the freshwater streams of Carolina, North America; and which is still its sole representative. It is an example of the Sauroid fishes of Agassiz, and is remarkable for the cellular structure of its air-bladder, which, as Cuvier remarks, is similar to the lung of a reptile.

AMIA′NTHUS. (Gr. ἀμιαντος.) A term applied to asbestus, in consequence of the resistance which it affords to the action of fire.

A′MIDES. Compounds containing a base apparently composed of 1 atom of nitrogen, and 2 of hydrogen. The term Ammonide, from their resemblance to ammonia, would perhaps be more correct.

A′MIDINE. The soluble part of starch.

AMID-SHIPS. A nautical term, denoting the middle of the ship, either with respect to her length or breadth.

A′MMOCŒ′TES. (Gr. ἀμμος, *sand*, and κοιτη, *a bed.*) The name of a genus of Cyclostomous fishes, of which the 'pride,' or 'stone grig' (*Amm. branchialis*), is a well-known example. This fish buries itself in the sand or clay of the banks of rivers; has many of the habits of a worm; possesses a skeleton reduced to membraneous consistence; and ranks among the lowest of organised vertebral animals.

A′MMODYTES. (Gr. ἀμμος, *sand.*) The name of a Linnæan genus of apodal fishes, characterised by a compressed head, narrower than the body; and both elongated. Gill-openings large, with seven branchiostegal rays; dorsal fin extending nearly the whole length of the back; anal fin of considerable length; dorsal and anal fins separated from the caudal fin. The sand-eel (*Ammodytes tobianus* Lin.) and the sand-launce (*Ammodytes lancea* Cuv.) are examples of this genus.

A′MMON. In Mythology, apparently a Libyan divinity, adopted by the Greeks, and by them identified with their Jupiter.

> ——— "stat corniger illic
> Jupiter, ut memorant, sed non aut fulmina vibrans,
> Aut similis nostro, sed tortis cornibus Ammon."

The name appears to be derived from ἀμμος, *sand;* and the situation of his celebrated temple in an oasis, surrounded by African deserts, indicates his origin. Alexander visited the temple, and assumed the title of son of this divinity, in order to impose on oriental imagination. It possessed a celebrated oracle. The lines of Lucan, partly quoted above (*Pharsal.* lib. ix. lin. 510. &c.), describing the temple, and the refusal of Cato to visit it, and consult the Fates respecting an enterprise, of the justice of which he was convinced, are among the finest and best known portions of his poem.

AMMO′NIA. Volatile alcali. This important compound is chiefly produced artificially. It exists, combined with acids, in some of the saline products of volcanos, and, in very small quantities, it is discoverable in sea-water. It is found in putrid urine and in the salts produced by the decomposition of animal matter; it exists occasionally in very minute quantities in the air, especially in large towns where pit-coal is burned; and the small stellated crystals which are sometimes observed on dirty windows in London. consist of sulphate of ammonia.

Ammonia was originally obtained (in the form of muriate of ammonia) by burning the dung of camels, which was collected for the purpose in Egypt, especially about the temple of Jupiter Ammon (whence the term sal ammoniac). It was afterwards procured by the distillation of putrid urine: at present, the demand for ammonia in its various states and combinations is in this country chiefly supplied from two sources; the distillation of pit-coal, and that of refuse animal substances, such as bone, clippings and shavings of horn, hoof, &c.

When coal is distilled (*see* GAS), a large quantity of ammoniacal liquor, as it is called, is formed, to which sulphuric or muriatic acids are added so as to form a sulphate or a muriate of ammonia. When the animal substances just mentioned are distilled, a quantity of impure ammonia passes off with the other products, which is also converted into sulphate or muriate of ammonia.

Pure ammonia is obtained in the form of a gas, by heating a mixture of quicklime and muriate of ammonia. It is very pungent and acrid; and so soluble, that one measure of water absorbs nearly 500 of gaseous ammonia: this solution is known under the name of liquid ammonia, and is used in medicine. Ammonia is a compound of nitrogen and hydrogen; it consists of

Nitrogen	1 atom	=	14	82·35
Hydrogen	3 . .	=	3	17·65
	1		17	100·00

It is decomposed when passed through a red-hot tube, and every 100 volumes of ammonia are resolved into 200 volumes of a mixture of 3 volumes of hydrogen and 1 of nitrogen.

Carbonate of ammonia is used in medicine as a stimulant, and frequently employed, under the name of smelling salt, as a restorative in faintness. It is obtained by sublimation from a mixture of muriate of ammonia and carbonate of lime. Muriate of ammonia has been above referred to as the common source of pure ammonia. Sulphate of ammonia is also manufactured for the same purposes.

Ammonia is recognised by its pungent smell, by its transient alcaline effect upon vegetable colours, and by producing white fumes when approached by muriatic acid. Thus, if we burn a piece of quill, and hold a glass rod dipped in muriatic acid near the smoke of it, dense white fumes appear, announcing the presence of ammonia, formed by the action of heat upon the animal matter.

AMMONI′ACUM. A gum resin used in medicine: it is imported in drops and cakes from Africa and the East Indies, and is said to be the produce of the Dorema ammoniacum. It is of a pale buff colour, and stands in the materia medica among the mildly stimulating but uncertain expectorants. It is sometimes applied externally in the form of a plaster.

A′MMONITE, AMMONITES. An extinct genus of molluscous animals which inhabited convoluted chambered siphoniferous shells, sometimes called Cornua ammonis, and vulgarly snake-stones. From their affinity to the nautilites, and the known organisation of the animal of the pearly nautilus, fossil shells of this genus are referred to the Tetrabranchiate order of Cephalopods, and constitute the typical genus of the second family of that order (*Ammonitidæ*). They are characterised by their conspicuous whorls, and the marginal-external position of the siphon. They abound in the strata of the secondary formation, varying from the size of a bean to the dimensions of a coach-wheel. Their name is derived from their resemblance to the horns upon the statue of Jupiter Ammon.

AMMONI′TIDÆ. A family of Cephalopods, with chambered syphoniferous shells, characterised by the septa being sinuous, with lobated margins.

AMMO′NIUM. A name given by Davy to the hypothetical base (supposed to be metallic) of ammonia. According to the hypothesis of Berzelius, ammonium is a compound of 1 volume of nitrogen with 4 volumes of hydrogen.

AMMO′PHILA. (Gr. ἀμμος, *sand*, and φιλεω, *I love.*) The name of a genus of hymenopterous insects, called sand-wasps. The generic characters are, proboscis conic, inflected, concealing a bifid, retractile, tubular tongue; jaws forcipated, 3-toothed at the tip; antennæ filiform in each sex, with about 14 articulations; eyes oval; wings plane; sting pungent, concealed within the abdomen.

AMMUNI′TION. In Military Language, signifies all sorts of warlike stores and provisions, but more especially powder and ball.

A′MNESTY. (Gr. ἀμνηστια, *oblivion.*) In Politics, freedom from penalty, granted by a solemn act to those guilty of some crime. Usually, by an act of amnesty is meant one passed to comprehend a number of individuals guilty of offences of a political nature, as rebellion, &c. Among remarkable amnesties in modern European history, may be cited, that granted on the restoration of Charles II., from which were excepted those concerned in the death of Charles I.; that granted on the second restoration of the Bourbons, in January, 1816, from which, besides the regicides, several others were excepted by name; and the law of amnesty for political offences in France, in 1836.

A′MNION. (Gr. ἀμνος, *a lamb.*) The membrane which surrounds the fœtus in utero: it includes a thin watery fluid, the liquor amnii.

A′MNIOS. In Botany, a thin, semitransparent, gelatinous substance in which the embryo of a seed is suspended when it first appears, and on which the embryo appears to feed in its early stages. Sometimes it is wholly absorbed; sometimes a portion of it is solidified in the form of albumen; occasionally, as in the cocoa-nut, a portion is consolidated into albumen, and a portion remains always in a fluid state.

AMNIO′TIC ACID. An acid supposed to be peculiar to the liquor amnii of the cow, but now known to belong to the liquor of the allantois.

AMO′MEÆ. (*See* AMOMUM.) One of the names of the plants more commonly called Zingiberaceæ.

AMO'MUM. (hhamâmâ, Arabic; ἄμωμον, of the Greeks.) A Zingiberaceous plant, with aromatic seeds, much employed under the name of cardamoms, grains of Paradise, &c. The species occur exclusively in the hottest parts of India and Africa.

AMO'RPHOUS. (Gr. ἀ, without, and μορφη, *form.*) Bodies devoid of regular forms.

AMPELI'DEÆ. Botany. (Gr. ἀμπελος, *a vine.*) One of the names of the natural order Vitaceæ.

A'MPELIS. The name of a Linnæan genus of Passerine birds, characterised by a straight convex beak, of which the upper mandible is the longer, and is subincurved, and emarginate on both sides. The Bohemian chatterer, or wax-wing (*Ampelis garrulus*), Linn., is a well known species of this genus; but is referred in the recent systems of Ornithology to a distinct section or subgenus, retaining the name of Bombycilla, originally applied to it by Brisson.

AMPHI'BIANS, AMPHI'BIA. (Gr. ἀμφι, *both*, and βιος, *life;* having the faculty of existing both in water and on land.) In modern Zoology, this term is restricted in its application to those animals which possess organs for breathing water, and organs for breathing air, or gills and lungs conjointly. Many cold-blooded animals, from the slowness of their circulation and the great capacity of their lungs in proportion to the vascular surface which alters the chemical state of the contained air, can remain a long time under water without being necessitated to seek the surface for a fresh supply: such are all the Vertebrata called Reptilia by modern zoologists, and which Linnæus, from the above mentioned faculty, included under the term Amphibia: yet if these animals were kept submersed longer than the period necessary for renewing the air in their lungs, they would inevitably be drowned; they are, therefore, not strictly amphibious. Not so, however, with that small portion of the order which retain their branchiæ throughout life;—these perennibranchiate reptiles suffer nothing from a prolonged aquatic existence, but, on the contrary, are most affected by a too long continuance on dry land; a desiccation of their external fringed gills, according to some recent experiments on the Siren lacertina, occasioning their death. Those warm-blooded mammalia which have their general form and locomotive instruments adapted for aquatic life, as whales, porpoises, walrusses, and seals, are, from the rapidity of their circulation and the prodigious extent of the vascular and respiratory membrane of the lungs, still more dependent upon a fresh supply of air for their existence than the pulmonated reptiles, and are consequently further removed from a true amphibious organisation. This is, in fact, enjoyed by a very small proportion of the animal kingdom; besides the perennibranchiate reptiles, a few species of mollusca, as the Ampullaria, and some insects and crustaceans, are the only examples.

AMPHI'BIOLI'TE. (Gr. ἀμφιβια, and λιθος, *a stone.*) The name given by Linnæus to the parts of reptiles, or amphibia, which were changed to a fossil substance.

AM'PHIBOLE. (Gr. ἀμφιβολος, *equivocal.*) A name which some mineralogists apply to hornblende, because it may be mistaken for augite.

AMPHIBO'LI. In Ornithology, the name of a family of scansorial birds, in the system of Illiger, including those in which the external posterior toe is versatile.

AMPHIBO'LOGY. (Gr. ἀμφι, *about*, and λογος, *discourse.*) In Rhetoric, an equivocal phrase or sentence, of which the sense may bear more than one interpretation.

AMPHI'CTYO'NIC COUNCIL. This was a congress of the deputies of twelve northern Greek tribes, viz. Thessalians, Bœotians, Dorians, Ionians, Perrhæbians, Magnetes, Locrians, Œnianians, Achæans of Phthia, Malians, Phocians, and Dolopians, or Delphians. In the Dorians and Ionians were included the Lacedæmonians and Athenians, who each sent one deputy. Each of these tribes had two representatives in the council called the Hieromnemon (*ιερομνημων*) and Pylagoras (*πυλαγορας*). The congress met twice every year; in the spring at Delphi, and at Thermopylæ in the autumn. Its functions do not seem to have been of a political nature, further than to see that no member of the union was destroyed; but were chiefly directed to religious matters, and more especially the protection of the temple of the Delphian Apollo. The principal ancient authorities which we possess respecting the objects and constitution of the amphictyonic council, are to be found in the orations of Æschines and Demosthenes: the 16th book of Diodorus Siculus; 9th of Strabo; and 10th of Pausanias. See also Ant. Van. Dale's *Dissertationes*, Amst. 1702; Paper by Valois, in the *Mém. de l'Ac. des Inscripions*, *&c.*, iii. 191. v. 405.; St. Croix, *Des Gouvernemens Féderatifs;* Tittmann's *Prize Essay on the Amphictyons;* and Muller's *Hist. of the Dorians.*

AMPHIGA'MOUS. (Gr. ἀμφι, in the sense of *doubtful*, and γαμος, *marriage.*) The most imperfect of all plants, having no trace whatever of sexual organs They form one of the classes in De Candolle's Natural System. (See BOTANY.)

AMPHI'PNEUSTS. (Gr. ἀμφις, *on both sides*, and πνεω, *I breathe.*) Merrem so calls a tribe of reptiles comprehending those which have both lungs and gills at the same time, as the true amphibia or perennibranchiates.

AMPHIPODS. (Gr. ἀμφις, *on both sides*, and πους, *a foot; feet diversely conformed.*) The third order of crustaceans in Latreille's arrangement, and the only one in which subcaudal natatory feet co-exist with sessile eyes.

AMPHI'PROSTYLE. (Gr. ἀμφι, *both or double*, προ, *before*, στυλος, *a column.*) In Architecture, a term applied to a temple having a portico or porch in the rear as well as the front, but without columns at the sides. This species of temple never exceeded the number of four columns in front and four in the rear. It differed from the temple in antis, in having columns instead of antæ at the angles of the portico.

A'MPHISBÆ'NA. (Gr. ἀμφι, *both*, βαινειν, *to walk.*) A genus of serpents or Ophidian reptiles, in which the tail and head are equally obtuse, and the scales of the head so similar to those on the back, as to render it difficult, on a cursory inspection, to distinguish one extremity of the body from the other. Hence these reptiles have been supposed to have the power of creeping backwards or forwards with equal facility.

AMPHI'SCII, or AMPHI'SCIANS. (Gr. ἀμφι, *about*, and σκια, *shadow.*) A term used by the ancient geographers, to denote the inhabitants of those climates in which the shadows, at noon-day, fall in opposite directions at different times of the year; that is to say, towards the north when the sun at noon is to the south of their zenith, and towards the south when the sun is to the north of their zenith. The term consequently applies to the people who live between the tropics.

AMPHITHE'ATRE. (Gr. ἀμφι, *about*, and θεατρον, *a theatre.*) In Architecture, a double theatre, or one of an elliptical figure; being, as its name imports, two theatres joined at the line of the proscenium; by which contrivance all the spectators, being ranged round on seats rising the one above the other, saw equally well what was passing in the arena, or space inclosed by the lowest range of seats. The origin of the amphitheatre was among the Etruscans, to whom also are attributed the first exhibitions of gladiatorial fights. From these the Romans acquired the taste for such shows, which they communicated to every nation subject to their dominion. Athenæus says, "Romani, ubi primum ludos facere cœperunt, huic asciti artifices ab Etruscis civitatibus fuerunt, sero autem ludi omnes qui nunc a Romanis celebrari solent, sunt instituti." (L. iv. cap. 17.) The most extraordinary edifice remaining in Rome is the amphitheatre, generally called the Coliseum, begun by Vespasian and finished by his son Titus. Words are inadequate to convey a satisfactory idea of its stupendous and gigantic dimensions.

> "Omnis Cesareo cedat labor amphitheatro,
> Unum pro cunctis fama loquatur opus,"

says Martial. It covers five English acres and a quarter of ground; the walls are of the height of 166 feet; it had seats for 87,000 spectators, with standing room for 22,000 others; and a vast arena, where thousands of gladiators and wild beasts contended at once—

> "Butcher'd to make a Roman holiday!"

This magnificent ruin has suffered much from earthquakes, and the destroying influence of time; and to the disgrace of the Papal government, it was allowed to be used, in comparatively recent times, as a convenient quarry, whence the materials of many modern edifices have been derived.—Still, however, its remains are such as to astonish the spectator;—

> A ruin – yet what ruin! From its mass,
> Walls, palaces, half-cities, have been rear'd;
> Yet oft the enormous skeleton ye pass,
> And marvel where the spoil could have appear'd.

Latterly, more attention has been paid to the preservation of this noblest monument of Imperial Rome. The walls have been propped up in some places, and sentinels have been placed for its protection.—Besides this amphitheatre, there were three others in Rome, namely, the Amphitheatrum Castrense, probably built by Tiberius, on the Esquiline; that of Statilius Taurus; and that built by Trajan, in the Campus Martius. The other principal amphitheatres were those of Otricoli, on the Garigliano, of brick, Puzzuoli, Capua, Verona, the foot of Monte Casino, Pæstum, Syracuse, Agrigentum, Catanea, Argos, Corinth, Pola in Istria, Hipella in Spain, Nismes, Arles, Fréjus, Saintes, and Autun. This last has four stories, similar in that respect to the Coliseum. But that in the most perfect state is the amphitheatre of Verona, which, with the exception of the exterior wall, is still perfect. The first that were erected, were, as we learn from Pliny, constructed of wood, and usually seated in the Campus Martius, or in some place out of the city. Accidents occurring from their insecurity, they were abandoned for the more substantial species of fabric whereof we have been speaking. The first person

who is said to have erected an amphitheatre in Rome, was Caius Scribonius Curio, in the games he gave to the people on the occasion of his father's funeral obsequies. Determined to surpass, in the way of games, all that had hitherto been seen, he constructed two theatres of wood, back to back, which, after the theatrical representations had been finished, were turned round with the spectators still in them, leaving the stages and scenery behind, and, by their opposite junction, forming a perfect amphitheatre, in which the people were gratified with a show of gladiators. The part in which the gladiators fought was called the arena, from being usually covered with sand to absorb the blood spilt in the conflicts for which it was used. The arena was encompassed by a wall, called the podium, fifteen or sixteen feet in height, immediately round which sate the senators and ambassadors. As in the theatres, the seats rose at the back of each other; fourteen rows in the rear of the podium being allotted to the equites, and the remainder for the public generally, who sate on the bare stone, cushions being provided for the senators and equites. Though generally open to the sky, there were contrivances for covering the whole space with a sort of awning. The avenues by which the public entered were many in number, and bore the name of vomitoria. See the work of Maffei, *Degli Amfiteatri;* and the section on Amphitheatres in his learned and excellent work, Verona Illustrata. The modern history of the Coliseum is given at considerable length in Hobhouse's Illustrations to Childe Harold.

AMPHITRI'TE. The name of a genus of cephalobranchiate or tubicular Annelides, characterised by golden-coloured short bristles, arranged like a crown, in one or two rows, on the anterior part of the head. One species inhabits the south coast of England, and forms for its habitation a very delicate, straight, conical tube of grains of sand, agglutinated together by the mucus exuded from the skin: this is the *Amphitrite auricoma.*

AMPHI'TROPAL. (Gr. ἀμφι, *round*, and τρεπω, *I turn.*) In Botany. This is said of an embryo which is turned round albumen, or curved upon itself in such a manner that both its ends are presented to the same point.

AMPHIU'ME, AMPHIU'MA. A genus of true amphibious reptiles, with a persistent branchial orifice on each side of the neck; palatal teeth in two longitudinal rows; a lengthened body, and four rudimental extremities, each divided either into three or two toes according to the species.

A'M'PHORA. (Gr. ἀμφορεος, *two-handled.*) In Sculpture and ornamental Architecture, a vase or measure having two handles, used as a measure for liquids by the Greeks and Romans: they are frequently applied as ornaments on sarcophagi, &c.

AMPHORA. A kind of earthenware vase with two handles, used by the Romans to hold wine and other liquids. Also a liquid measure, containing probably about nine gallons; but its exact size is not satisfactorily made out.

AMPLE'XICAUL. (Lat. amplecto, *I embrace*, and caulis, *a stem.*) A leaf or bract whose base projects on each side, so as to clasp the stem with its lobes.

AMPLIFICA'TION. In Rhetoric, the lengthening a discourse or a passage by the enumeration of minute circumstances, the employment of epithets, particularity of description, &c., with a view to produce a deeper impression. *Exaggeration* is properly a species of amplification, in which circumstances and facts are not merely dwelt upon, but represented beyond their true dimensions.

AM'PLITUDE. In Astronomy, denotes the angular distance of a celestial body, at the time it rises or sets, from the east or west points of the horizon. The amplitude of a fixed star remains the same all the year round; that of the sun or moon is constantly changing. At a given latitude, it depends on the declination of the object. Amplitude is sometimes used to denote the horizontal distance to which a projectile is expelled from a gun, or what is more frequently termed the range of the gun.

A'MULET. A substance worn about the person, and supposed to have the effect of protecting the wearer against some real or imaginary evils. Those of the Persians and Egyptians are said to have been small cylinders ornamented with figures and hieroglyphics. The Greeks and Romans employed for the same purpose a great variety of gems and small figures of deities, heroes, or animals, the bulla, and various other articles. Some of these were hung around the necks of children, to defend them from the evil eye. In more modern times, scraps of paper or parchment inscribed with verses of the Bible, or with magical characters and jargon, have often been used for the same purposes. The celebrated Arabian talismanic medals are called by the Arabs Ain, from the first letter of the inscription always beginning with that character.

AMYGDA'LEÆ. (Gr. ἀμυγδαλον, *an almond.*) A division of Rosaceous plants, comprehending the peach, the plum, the apricot, and similar objects. The species have all a fleshy or succulent fruit, gum in their bark, and hydrocyanic acid in their leaves. They occur principally in cold and temperate latitudes.

AMY'GDALOI'D. (Gr. ἀμυγδαλον, *an almond*, and εἶδος, *a form.*) Almond-shaped. The term is applied to certain rocks in which other minerals are occasionally imbedded like almonds in a cake.

AMYRI'DA'CEÆ. Balsamic exogenous plants, consisting of shrubs or trees, found almost exclusively in the Tropics. Bdellium, balsam of copaiva, gum elemi, and balsam of Tolu, are all produced by species of this order, the type of which is the genus amyris (myrrha, *myrrh*).

ANA. A termination of the neuter plural form in Latin, used in English and French to denote anecdotes of eminent persons, or selections from their works. The first of the French collections termed "Ana," and from which that denomination originated, is the Valesiana; containing detached observations on passages of classical antiquity by the celebrated scholar Valois, or Valesius: it appeared at Paris in 1695. The Menagiana (Paris, 1715) is a more amusing work, consisting of anecdotes, criticisms, and miscellaneous observations on all possible subjects, attributed to the academician Ménage. The popularity of this work produced a multitude of other "Ana:" among which may be mentioned the Huetiana, 1723; the Scaligerana, Thuana, Poggiana, and a variety of similar books, consisting of extracts from the works of distinguished writers, or of thoughts or sayings attributed to them.

ANA, or AA (contracted from ana). In Medical prescriptions, implies "of each."

ANABA'PTISTS. Properly, all sects are so called, that insist upon the repetition of baptism upon admission into their communion, from a notion of the invalidity of the religious ceremonies of other denominations. There were several such in the early period of the church, as the Cataphrygians and Novatians: but they are to be distinguished from the sects which arose in the 15th and the beginning of the 16th centuries, under the papal dominion, especially in Germany; and adopted, in their ignorance and fanaticism, preposterous notions of the qualifications requisite for admission into the visible church. Their idea of primitive society consisted in the rejection of all the customs and decencies of life; in the community of goods and of women; in uncompromising hostility to all modes of artificial life, and to government generally, as the foundation and sanction of social distinctions. They had, of course, no indulgence for the ordinances of any church but their own, and required baptism for themselves as the essential preliminary for admission within their pale. Early in the progress of the Reformation, finding their numbers daily increasing under the licentiousness of opinion which the unrestricted abuse of private judgment produced among a rude and uneducated people, they united in a hostile league against all existing institutions, and declared open war against the governments of Lower Germany. After committing the greatest atrocities, and causing an universal panic throughout Europe, their progress was arrested by a complete defeat in Saxony, in which their leader, Muncer, perished. The remnant, however, escaping, established their opinions with more or less moderation of tone in Holland and elsewhere. Some of the party seized, soon after, upon the town of Munster, overthrew the magistracy, and established society upon their own principles; but eventually were put down with great slaughter. (See, as to the Munster Anabaptists, Mosheim's *Ecclesiastical History*, sect. ii. part ii. c. 3., where reference is made to the best works on the subject.) It should be observed, that the anabaptists were not dependent upon religious views only for their support, but that the war soon assumed the character of a struggle between the lower and upper classes; and the enormities committed by the insurgents must be attributed as much to revenge for oppression as to religious fanaticism. (*See* BAPTISTS.)

A'NABAS. A genus of Acanthopterygious fishes, in which the surface of the pharynx is broken into numerous little branched appendages and cells, capable of retaining water, and of gradually dropping it into the branchial cavity, so as to moisten the gills; whereby these fishes have the curious faculty of voluntarily quitting the water, creeping about on land, and even, it is said, of climbing trees. The only known species (*Anabas testudineus*) is the *Perca scandens*, or climbing perch, of the older naturalists.

A'NABLEPS. (Gr. ἀναβλεπω, *I raise the eyes.*) A name applied to a genus of malacopterygian viviparous fishes, characterised by a remarkable projection of the eyes from the sides of the head, and a still more singular structure of the cornea and iris, from which there result two pupils, and the eyes appear to be double on each side, although they have but one crystalline lens, one vitreous humour, and one retina.

ANACLA'STICS. (Gr. ἀνα, *up*, and κλαω, *I break.*) That part of Optics in which the refraction of light is considered, commonly called Dioptrics. The term was

applied by Desmairau to the apparent curves formed by the bottom of a vessel when looked at through a body of water.

ANACA'RDIA'CEÆ. A natural order of exogens, founded upon the *Anacardium occidentale*, or cashew nut. It consists of tropical trees, often abounding in a fluid resin of extreme acridity, but forming a valuable varnish in some cases. Marking nuts, the fruit of Semicarpas anacardium, black Burmen varnish from Melanorhœa usitatissima, mastich, Scio turpentine, pistacia nuts, sumach, are all produced by various species of this extensive natural order.

ANA'CHORITE. See ANCHORITE.

ANA'CHRONISM. (Gr. ἀνα, *backward*, and χρονος, *time.*) An inversion or disturbance in the order of time: as where, in Shakspeare's King John, cannon are introduced, which were not in reality employed until a hundred years afterwards.

A'NACOLU'THON. (Gr. ἀνακολουθον, *not following.*) A Grammatical term, denoting the want of sequence in a sentence, one of whose members corresponds not with the remainder. This figure recurs more frequently in the Greek than in any other language.

ANA'CREO'NTIC. In Poetry, a species of ode devoted chiefly to the praises of love and wine; —

> "Quid nisi cum multo venerem confundere vino,
> Præcipit lyrici Teia musa Senis?"

The name is derived from Anacreon of Teos, who flourished in the sixth century B.C. The genuineness of the Odes which pass under his name, has, however, been questioned by some critics; but some of them are, at all events, very ancient; and they have been universally admired for their simplicity and sprightliness; —

> "All thy verse is softer far
> Than the downy feathers are,
> Of my wings, or of my arrows,
> Of my mother's doves and sparrows;
> Graceful, cleanly, smooth, and round,
> All with Venus' girdle bound."

The poems of Anacreon have been rendered familiar to the English reader by the translations of Cowley and Moore. The best editions of the original are those of Fischer and Brunck.

ANÆSTHE'SIA. (Gr. ἀ, *without*, and αἰσθανομαι, *I feel.*) Diminution or loss of the sense of touch.

ANAGLY'PHIC. (Gr. ἀνα, *upon*, and γλυφω, *I carve.*) In antique Sculpture, chased or embossed work on metal, or any thing worked in relief. When raised on stone, the production is a cameo. When sunk or indented, it is a diaglyphic or an intaglio.

ANAGNO'STA. (Gr. ἀναγινωσκω, *I read.*) A domestic servant employed by wealthy Romans to read to them at their meals and on other occasions. The ancient monks and clergy preserved the same custom, and name.

A'NAGRAM. (Gr. ἀνα, *back*, and γραφω, *I write.*) The most proper, and most difficult, species of anagram is that which is formed by the reading of the letters of a word or words backwards: as "evil," "live."

> "Live, vile, and evil, have the self-same letters;
> He lives but vile, whom evil holds in fetters."

A less perfect anagram is that which is made by transposition of letters ad libitum: and an anagram in which the transposition is helped out by the admission of letters not in the original word, or the rejection of some of those which it contains, is termed impure. The manufacture of anagrams, particularly out of proper names, formed a favourite exercise of ingenuity in the 16th and 17th centuries; when a common mode of flattery was by inventing some complimentary transposition of the letters of the name of the person addressed. But none of the anagrams of that period exceed, in felicity, Dr. Burney's on Lord Nelson: "Horatio Nelson," "Honor est a Nilo." Of all the extravagances occasioned by the anagrammatic fever, when at its height, none probably equals what is recorded of an eccentric Frenchman in the 17th century, André Pujom. He read in his own name the anagram "pendu à Riom" (the seat of criminal justice in the province of Auvergne), felt impelled to fulfil his destiny, committed a capital offence in Auvergne, and was actually hung in the place to which the omen pointed.

ANAL. In Ichthyology, the fin which is placed between the vent and tail, and expands perpendicularly.

ANAL GLANDS. Comp. Anat. Organs for secreting substances, sometimes attractive, but generally repulsive in their properties, and applied to purposes of defence; they present every grade of the glandular structure, from the simple cæcum, or tube, to the conglomerate mass; developed from, and consequently always opening into, the termination of the intestine, near the anus. In insects, the sweet fluid ejected by the aphides, and of which the ants are fond, is, at least in some species, the product of secerning tubules opening near the anus. Odorous substances, — sometimes fragrant, sometimes fetid, — are in different species of insects respectively emitted from the same part; and the singular defensive acrid vapours discharged explosively by the insects called "bombardiers," are the products of anal glands. In the mollusks, the most remarkable example of the anal glands is presented by the higher organised cephalopods, where they are represented generally by a single, sometimes by a bilobed or trilobed, cyst, with part of its parietes spongy and glandular, and which secretes the inky fluid which these animals eject to blacken the water around them for the purpose of concealment in time of danger. Among fishes, an anal bag opens by a single narrow duct, as in cephalopods, into the termination of the rectum, in rays and sharks; but it no longer exercises the function of a secerner of colouring matter. In reptiles, the anal bags are either single, double, or triple; and in many species, as in frogs and tortoises, are developed to a great size, and serve for aquatic respiration. In crocodiles they are two in number, and emit into the cloaca a muco-caseous secretion, without any strong odour. In birds, the anal follicles have a similar function, but they are aggregated into a single cavity, which is called the "bursa Fabricii." In quadrupeds, the anal follicles are generally collected into two sacciform groups, each having an opening near the verge of the anus. The insupportably disgusting odour of the secretion of these glands has rendered some of the viverrine quadrupeds, as the skunk, &c., proverbial; in others, the odour is not stronger than serves to attract the individuals of the same species to one another, which is the common function of the anal glands in this class of animals.

ANAL VALVES. A mechanical structure for defending the terminal orifice of the intestines in some of the cephalopods, which swim forwards, from the retrograde entrance of foreign or noxious substances. This mechanism is required from the position and direction of the anal opening, which is turned forwards towards the base of the funnel or respiratory channel.

ANA'LCIME. A variety of zeolite, which by friction becomes weakly electric: from ἀναλκις, *weak*.

ANALE'CTA. A servant in great Roman houses, whose duty it was to collect the scraps after a meal; whence he derived his name, from the Greek ἀναλεγω, *I pick up*.

ANALE'MMA. (Gr. ἀναλαμβανω, *I take up.*) In Geometry. An orthographic projection of the sphere on the plane of the meridian. In this projection the eye is supposed to be placed at an infinite distance. Every great circle whose plane is perpendicular to the plane of projection, — the horizon, for example, — is represented by its diameter; every small circle perpendicular to the same plane is represented by the chord which forms its diameter. A small circle parallel to the plane of projection, is represented by a circle. Every circle, great or small, of which the plane when produced does not pass through te eye, or is not perpendicular to the plane of projection, will be seen obliquely and under the form of an ellipse. — Analemma also denotes an instrument of brass or wood on which the projection is made, (the plane of projection being the solstitial colure,) with a moveable horizon attached to it, by means of which some of the common astronomical problems may be solved, though not very exactly. Ptolemy wrote a treatise on the Analemma, of which there is a Latin translation from an Arabic version, with a commentary by Commandine. According to Delambre, it contains only some complicated rules for computing the true values of the arcs of the sphere from the straight lines by which they are represented on the analemma. Since the invention of trigonometry, contrivances of this sort have become useless.

A'NALE'PSY. (Gr. ἀναλαμβανω.) A species of epileptic attack of sudden and frequent recurrence.

ANALE'PTIC. A restorative medicine.

A'NALOGUE. A body that resembles another. A fossil shell of the same species as a recent one, is its analogue.

ANA'LOGY. (Gr. ἀναλογος, *according to rule or proportion.*) In Geometry, signifies the same thing as proportion, or the equality or similitude of ratios. (*See* PROPORTION, and RATIO.)

ANALOGY. In modern Zoology, this term is restricted to the relation which animals bear to one another in the similarity of a smaller proportion of their organisation: thus, the Ascalaphus italicus, in the length and knobbed extremities of its antennæ, the colouring of its wings, and its general aspect, exhibits a striking resemblance to a butterfly; but in all the essential parts of its organisation it adheres to the neuropterous type of structure; its relation to the Lepidoptera is therefore said to be one of analogy, while it is connected to the ant-lions by the order of affinity. As it has been found in some instances, that two series of animals, arranged according to the greater amount of resemblances, or the relation of affinity, are connected to one another by analogical resemblances at given points of the series, the relation of analogy has been regarded as differing from that of affinity not only in degree, but in kind. If a zoologist, for example, were led, by a too superficial glance at the external resemblances of two animals, to

place them in the same series contiguous to one another, and it were discovered that the resemblance was but skin-deep or limited to a temporary state of being, as a stage of metamorphosis, but contradicted by a dissimilarity of a greater proportion of the internal organisation, then it would be said that he had mistaken a relation of analogy for one of affinity; a phrase which the reader, however, will readily perceive, merely expresses the fact, that a false judgment had been formed, from not taking into consideration the whole of the points of comparison necessary for determining the mutual relation of animals to each other.

Analogy. In its Rhetorical sense, signifies a similarity of two things in their relation to a third, though there may be the greatest difference in their structure, form, colour, &c.: thus, a hat is analogous to a turban, and both are analogous to a bonnet, having a similar relation to the head of the wearer. In this sense, a porpoise is analogous not only to a fish, but to every other animal which habitually moves and seeks its food in the water. It often happens, however, in Zoology, that a similarity of relationship to a medium of locomotion, a kind of food, &c., is accompanied with a certain amount of corporeal and organic resemblance; and this is necessary to constitute an analogy in the zoological sense, though by no means in the strictly logical application of the word.

Analogy. In ordinary Language, denotes a relation or similarity between different things in certain respects. The conclusions to which we are led concerning one thing, by reasoning from our experience concerning another similar thing, form what is termed analogical knowledge. The word analogy is generally employed to designate an imperfect degree of similarity. Thus, a physician, arguing, from the effects which he had seen produced by a drug on one man, to its probable effects on another man, would be said to reason from experience: but reasoning from the effects produced on an inferior animal, to the probable effects on man, would be, more properly, reasoning by analogy.—In Rhetoric, the word analogy is employed in a somewhat stricter sense; it designates, not the specific resemblance between two objects, but a resemblance between the relations in which they stand to other objects. Thus, to term youth "the dawn of life," is said to be a metaphor by analogy; not because of any actual resemblance between youth and morning, but because the one is to life, what the other is to the day.—In Mathematics, analogy signifies the similitude of certain proportions.—In Grammar, it means a conformity in the principles of organisation of different words or collections of words.

ANA'LYSIS. (Gr. ἀναλυω, *I dissolve.*) A Greek word, which signifies the resolution of a thing into its component parts.—In Logic, analysis is used in opposition to synthesis, as a method of arriving at adequate definitions. In the synthetical method, we begin by assuming some quality which the subject is known to possess. Finding this to be common to other subjects than the one we wish to define, we add on some further property and so on, until we have adequately distinguished it from all other things. Thus, man is an animal, man is a hot-blooded animal, man is a hot-blooded viviparous animal, &c. &c., may be taken as a specimen of a synthetical process. In analysis we should reverse the method; assuming the most distinguishing characteristic, and descending, through successive gradations, to that which is least so. Correspondently with this distinction, an analytical proposition is one in which the subject is implied in the predicate: e. g. "matter is extended." A synthetical proposition, on the contrary, is that in which the terms have no necessary connection: e. g. "John is tall:" "the world is round." As applied to mental phenomena, analysis is the referring them to the acts or faculties of the mind which they necessarily imply, either as contemporaneously contributing to their production, or as rendering their production possible by their past operation.

The distinction frequently made between analytic and synthetic reasoning, rests on a somewhat vague use of language. Strictly speaking, all reasoning can be but of one kind. A process of ratiocination admits, however, of being reversed: i. e. we may make certain assumptions, and from them form certain legitimate deductions; and we may then proceed to take the truths thus deduced for granted, and by a counter-process arrive, as inferences, at what, in the former case, were the grounds from which we started. Here it is evident that the distinction lies not in the reasoning, but in the subject-matter concerning which we reason.

Analysis. In Chemistry, this term is applied to the resolution of compound bodies into their elements. It is either qualitative or quantitative. Qualitative analysis consists in the determination of the component parts, merely as respects their nature, and without reference to their relative proportions: it is an imperfect, and often a very easy, operation, as compared with quantitative analysis, by which we determine not merely the components of a compound, but their relative proportions: to effect this, much scientific skill and practical dexterity are required, more especially in the identification of new substances. The theory of definite proportionals, or the Atomic Theory, as it is usually called, has materially facilitated many analytical processes, and is especially valuable as furnishing an unerring test or criterion of the general accuracy of the results.

In reference to chemical analysis generally, but more especially as regards organic products, we often employ the terms proximate and ultimate analysis: the former referring to the immediate combinations which form the subject of experiment; the latter, to their final resolution into elementary principles. Thus, in regard to sulphate of lime, it is resolved by proximate analysis into sulphuric acid and lime, and these are called its proximate elements; but sulphuric acid is itself a compound of oxygen and sulphur; and lime, of oxygen and calcium; oxygen, sulphur, and calcium, therefore, are the results of the ultimate analysis of sulphate of lime; and there are many theoretical points in chemistry dependent upon the views which are taken of the various groupings of these ultimate principles. Wheat flour is a compound of starch and gluten; starch is compounded of oxygen, hydrogen, and carbon; and gluten, of the same elements with the addition of nitrogen; so that the ultimate components of wheat, are oxygen, hydrogen, carbon, and nitrogen.

Analysis. In Geometry, a method of conducting geometrical inquiries, invented by the philosophers of the school of Plato, or, according to Theon of Alexandria, by Plato himself, and one of the most ingenious and beautiful contrivances in the Mathematics. The essence of the analytic method of establishing the truth of a proposition consists in assuming the proposition enunciated to be true, and deducing consequences from that supposition till a conclusion is arrived at manifestly true or manifestly false; or at least known to be true or false by its agreement or disagreement with some proposition which has already been demonstrated. Analysis is thus the converse of synthesis, or composition,—a form of reasoning by which we ascend, through a series of propositions, from some known truth to the conclusion we are in search of. The distinction between analysis and synthesis, as well as the definition of the two terms in the sense in which they were understood by the ancient geometers, is concisely given by Pappus, in the Preface to the Seventh Book of his Mathematical Collections. "Analysis," says Pappus, "is the course which, setting out from the thing sought, and which for the moment is taken for granted, conducts by a series of consequences to something already known, or placed among the number of principles admitted to be true. By this method, therefore, we ascend from a truth or a proposition to its antecedents; and we call it analysis, or resolution, as if indicating an inverted solution. In synthesis, on the contrary, we set out from the proposition which is the last in the analysis; and proceed by arranging, according to their nature, the antecedents which present themselves as consequents in the analytic method, and combining them together till we arrive at the conclusion sought. Analysis may be distinguished into two kinds: in the first, which may be called contemplative analysis, we propose to discover the truth or falsehood of an affirmed proposition; the other belongs to the solution of problems, or the investigaton of unknown truths. In the first we assume the subject of the proposition advanced to be true, and proceed through the consequences of the hypothesis till we arrive at something known. If this result is true, the proposition is true also, and the direct demonstration is obtained by stating in an inverse order the different parts of the analysis. If the ultimate consequence at which we arrive is false, the proposition was also false. In the case of a problem, we first suppose it to be resolved, and deduce the consequences resulting from that proposition till we arrive at something known. If the last consequence involves only something which can be executed, or is comprised among what geometers called data, the proposed problem can be solved; and the demonstration, or rather in this case the construction, is obtained, as in the former case, by taking the different parts of the analysis in an inverse order. If the last result is impossible, the thing demanded is also impossible."

The names of the ancient writers on the geometrical analysis have been preserved by Pappus in the preface before referred to: they are, Euclid, in his Data and Porismata; Apollonius, in his treatise De Sectione Rationis, and in his Conic Sections; Aristæus, De Locis Solidis; and Eratosthenes, De Mediis Proportionalibus; but of these only the Data of Euclid, and some fragments of Apollonius, have come down to our times. The subject has, however, been fully investigated by the moderns, and a complete system of the ancient geometrical analysis may be found in the works of Dr. Simson of Glasgow. (See also Leslie's Geometrical Analysis.)

By the term analysis the ancient geometers understood

a certain mode of reasoning altogether independent of signs or symbols, and which might be carried on by ordinary language. In its modern acceptation, analysis is synonymous with algebra, or the calculus, and is opposed, not to synthesis, but to geometry. In this sense the original meaning of the word is entirely lost sight of; and, instead of being used to denote a particular mode of reasoning, it rather indicates the instrument by which the reasoning is carried on. Algebra may be employed with advantage, whether the method of demonstration be analytical or synthetical.

One great advantage arising from the use of algebra in the solution of geometrical questions, consists in this, —that the demonstration is reduced to certain rules, and carried on by systematic processes; in consequence of which, the analyst, having reduced his problem to equations, can generally determine at a glance, whether the solution is possible or not. It must be admitted, that the demonstrations of many of the propositions of elementary geometry by the ancient methods have a peculiar elegance which the algebraic methods cannot always reach; but, in point of power and applicability, the modern analysis is vastly superior to the ancient. "The geometrical synthesis," says Laplace, "has the advantage of never losing sight of its object, and of illuminating the whole path which leads from the first axioms to their last consequences; whereas the algebraic analysis soon causes us to forget the principal object in order to occupy us with abstract combinations. But in thus isolating the objects, after having abstracted from them what is indispensable to arrive at the result he is in search of, in abandoning himself to the operations of analysis, and reserving all his forces to overcome the difficulties which it presents, the analyst is conducted to results inaccessible to synthesis. Such is the fecundity of analysis, that it is sufficient to translate particular truths into this universal language, in order to perceive a series of other new and unexpected truths arise from their mere expressions. No language is equally susceptible of the elegance which results from the development of a long series of expressions intimately connected with one another, and all flowing from the same fundamental idea. Analysis also unites with these advantages that of being always capable of leading to the simplest methods; for this purpose it is only required to apply it suitably, by a skilful choice of indeterminate quantities, and to give the results the form the most convenient for geometrical construction or numerical calculation. Modern geometers, convinced of the superiority of analysis, have especially applied themselves to extend its domain, and enlarge its limits."—(*Exposition du Système du Monde*, 4to. p. 423.)

Analysis is in general the instrument of invention; and it is supposed, not without reason, that the greater part of the discoveries, for which the mathematicians of the 17th century were distinguished, were made by its means, though they were given to the world in a synthetical form. It is evident, from the posthumous works of Pascal and Roberval, that they first obtained the solution of many of their problems by the method of indivisibles, and afterwards demonstrated the truth of their results in the manner of the ancients. Newton himself thought that a mathematical proposition ought not to be made public, or was not fit to be seen, till invested in a synthetic dress. Synthetic demonstration is now rarely met with in any other than the most elementary works; the algebraic analysis has become the ordinary intrument of mathematical investigation. "Nevertheless," says Laplace, "geometrical considerations ought not to be entirely abandoned; they are of great utility in the arts. Besides, it is interesting to figure to one's self in space the divers results of analysis; and reciprocally to read the affections of lines and surfaces, and all the variations of the motion of bodies, in the equations which express them. This connection of geometry and analysis throws a new light over both sciences; the intellectual operations of the latter, rendered sensible by the former, are more easily apprehended, and more interesting to follow; and when the imagination realises these images, and transforms geometrical results into laws of nature; when those laws, while they embrace the universe, unveil to our eyes its past and future conditions; the sight of this sublime spectacle affords the noblest of the pleasures reserved for the human race."—(*Exposition du Système du Monde*, p. 424.)

ANAMORPHO'SIS. (Gr. ἀνα, *backward*, and μορφη, *form.*) A term employed in Perspective, to denote a drawing executed in such a manner that, when viewed in the common way, it presents a confused or distorted image of the thing represented, or an image of something entirely different; but when viewed from a particular point, or as reflected by a curved mirror, or through a polyhedron, it recovers its proportions, and presents a distinct representation of the object.

ANAMORPHOSIS. In Botany, when any part assumes an appearance unusual with it. The calyx of the rose assuming the appearance of a fruit, the stipule of a prosopis become spiny, the stem of a cactus when succulent and tube-like, are cases of anamorphosis.

ANA'NAS. (Ananas, *Brazilian.*) The plant that produces the delicious pineapples of the gardens. It is of South American origin, but has been gradually dispersed through similar climates till it has become apparently wild in Africa and many parts of Asia, especially the Malayan Archipelago, where it arrives at a greater degree of excellence than in its native woods.

ANA'NDROUS. (Gr. ἀ, *without*, and ἀνηρ (genitive ἀνδρος), *a male or stamen.*) When flowers are destitute of stamens, they are usually called female flowers.

A'NAPÆST. (Gr. ἀναπαιστος.) A foot in Greek and Latin metre, consisting of two short syllables followed by a long being the name of the dactyle.

ANA'PHORA. (Gr. ἀναφορα, *raising up.*) In Rhetoric, a repetition of words or phrases at the commencement of sentences or verses. Thus in Cicero, Verr. iv. c. 10., *Verres calumniatores apponebat, Verres adesse jubebat Verres cognoscebat, Verres judicabat.*

ANAPLOTHE'RIUM. *See* ANOPLOTHERIUM.

A'NARCHY. (Gr. ἀ, *without*, ἀρχω, *I govern.*) In Politics, the constitution of a country in which not only lawful government, but regular government *de facto*, is superseded by force. Hence Milton metaphorically terms his personified Chaos an "Anarch."

ANARRHI'CHAS. A name conceived by Gesner and applied by Linnæus to a genus of spiny-finned osseous fishes, characterised by having their mandibular, palatine, and vomerine bones armed with large osseous tubercles, bearing on their summits small enamelled teeth; anteriorly the jaws support longer and more conical teeth: by means of this powerful dental apparatus the species of this genus, which inhabits the northern seas, called the "wolf-fish," is enabled to break and bruise the testaceous defensive coverings of shellfish, the soft parts of which form its ordinary food.

A'NAS. (Lat. anas, *a duck.*) The name of a Linnæan genus of Anserine birds, characterised by a large, broad, obtuse bill, furnished at the margin with numerous thin, transverse, projecting plates, and an obtuse papillose or ciliate tongue. The subdivisions of this extensive group of web-footed birds, which were indicated by Linnæus, have since been raised to the rank of genera (*see* ANATIDÆ), and the term Anas is now restricted to the species which present a flattened bill, the base of which is always of greater breadth than depth, as wide (or wider) at the extremity as at the beginning; with nostrils placed nearer the upper margin and base of the bill. The legs are shorter and placed farther back than in the geese (*Anser*); they have a shorter neck, and the windpipe is dilated at its lower end into two osseous capsules, of which the left is usually the larger. The ducks, thus characterised, are subdivided into those which have the hind toe provided with a membrane, and those in which it is naked. Both divisions are again broken up into numerous minor groups, which are distinguished by generic terms.

ANASA'RCA. (Gr. ἀνα, *through*, and σαρξ, *flesh.*) A diffusion of water through the cellular membrane of the limbs, as in dropsy.

ANA'STOMO'SING. When two parts, growing in different directions, meet and grow together, as the veins in leaves.

ANA'STOMO'SIS. (Gr. ἀνα, *through*, and στομα, *a mouth.*) The communications of the vessels of the body with each other.

ANA'STROPHE. A name given in Classical Philology to some species of inversion (*see* INVERSION) or departure from the usual order of succession in words. From the Greek ἀναστρεφω, *I overturn or invert.* Such phrases as mecum, vobiscum, &c., in which the preposition follows the word governed by it, or in which it is placed between two words governed by it, &c., are instances of anastrophe.

ANA'THEMA. (Gr. ἀναθεμα.) Properly, a thing laid by, consecrated, or devoted: hence a person upon whom the ban of the church is laid, is said to be anathematised, or in the Jewish phrase, to be "anathema." St. Paul says, "If we or an angel from heaven preach any other gospel to you than that which we have preached, let him be anathema:" and upon the authority of this and similar passages, the church assumed from the first the power of anathematising or excommunicating evildoers and heretics.

ANA'TIDÆ. The name of a family of web-footed birds, of the swan, goose, and duck kind, of which the genus Anas is the type.

ANA'TOMY. (From ἀνα, *through*, and τεμνω, *I cut.*) This term literally means *dissection*, but is generally understood to signify a knowledge of the internal structure of the human body, in the acquisition of which dissection is essentially necessary. The anatomy of other animals is usually designated Comparative Anatomy; and that of plants, Vegetable Anatomy; which see.

Although some anatomical knowledge must have been accidentally acquired by the earliest inhabitants of the

globe, and although there are several allusions in the early books of the Old Testament to the subject, no dissections of the human body were performed with a view to ascertain the position and structure of its internal organs, or to elucidate their functions, till a much later period.

Homer has, it is true, been complimented, and in some respects justly so, for the precision with which he describes the wounds of his heroes; and the ancient Egyptians are said to have acquired great anatomical skill by their practice in the art of embalming; but these, and similar statements, have no bearing upon the pursuit of anatomy as a science, or in connection with surgery, medicine, and physiology. Thales, Socrates, Xenophon, and Plato, are each quoted by anatomical historians, as having acquired no inconsiderable anatomical knowledge; Plato is even said to have anticipated the celebrated discovery of the circulation of the blood. "The heart," he says, "is the centre of the blood-vessels, the spring of the blood, whence it flows rapidly round: blood is the pabulum of the flesh, in order to the nutriment of which the body is intersected by canals, like those of gardens, to convey the blood like water from a fountain, to the remote parts."

The first author who is supposed to have written on human anatomy is Hippocrates; and the first recorded dissection was, probably, made by his contemporary Democritus of Abdera. This carries us back to about 400 years before the Christian era, from which period, to that of Galen, (that is, in the space of 600 years,) little progress seems to have been made in the knowledge even of the structure and position of the viscera of the body, much less in their uses and diseases.

It would appear from Galen that the most eminent anatomists of antiquity were Erasistratus and Herophilus, who taught anatomy in the celebrated school of Alexandria, and are said to have been the first who were authorised to dissect human bodies: hence, probably, the high rank which the school, founded by the Ptolemies, acquired, and maintained for several hundred years. The works of the above-mentioned anatomical professors have been lost, but they are abundantly quoted by their more immediate successors.

Among the Romans the first anatomist was, probably, Asclepiades, who flourished in the time of Pompey; and soon afterwards Rome became a celebrated seat of medical science. Celsus, Aretæus, and Galen, are the ornaments of this period; especially the latter, as an anatomist; though it appears probable that his descriptions were often taken from dissections of inferior animals, and applied to the corresponding organs of the human body: it is, however, said, that he anticipated many subsequent discoveries, and that a great part of his writings were for a long time unintelligible, till cleared up and explained by the labours of his successors.

During the dark ages anatomy sustained the fate of other branches of knowledge; and, with few exceptions, little progress was made in it, till the revival of learning in Europe. the prejudice, too, against the dissection of the human body was not only maintained, but sanctioned by the highest existing authorities. In the year 1315, a System of Anatomy was drawn up by Mundinus, chiefly, it is said, founded upon such parts of Galen's doctrines as had been preserved by the Arabians. This work deserves notice, as having been the anatomical text-book of the schools of Italy for a period of nearly 200 years. Mundinus is, indeed, celebrated by his contemporaries as the restorer of anatomy. Early in the fifteenth century, when learning began to revive in Europe, in consequence chiefly of the introduction of the writings of the Greek authors, numerous treatises on the Sciences made their appearance, amongst which anatomy formed a prominent subject; and among its most successful followers, the name of the celebrated Leonardo da Vinci may be recorded, although he apparently only pursued it in reference to his own art. (See the sketches annexed to Memorie Storiche di L. da Vinci, by C. Amoretti, Milano, 1804.) In reference to some of the drawings and their descriptions, preserved in the library of George III., and which he had access to, Dr. Hunter observes, that he saw with astonishment that Leonardo had been a deep student, "and was at that time the best anatomist in the world." We must give the fifteenth century the credit of Leonardo's anatomical studies, as he was fifty-five years of age at its close. At the beginning of the sixteenth century Berengarius and Massa wrote upon human anatomy; but such was the authority of Galen, even at that time, that few dared publish any statement or opinions contradicting those of their infallible master. About the middle, however, of the sixteenth century, this spell was broken by the celebrated Vesalius of Brussels, who taught anatomy at Paris and Louvain, and afterwards in Italy. He boldly demonstrated the errors of Galen; described accurately the dissections of the body, corrected and improved anatomical nomenclature, and insisted upon the necessity of diligence and actual observation in dissection, as the only solid foundation of successful medical and surgical practice. He had many opponents, and is said to have been detected in the very mischievous error for which he blames Galen; namely, that of describing the human viscera from dissections made upon quadrupeds.

Among the most remarkable contemporaries or immediate successors of Vesalius, were Fallopius and Eustachius,— the former of Padua, the latter of Venice; whose names, as annexed to their discoveries, have been handed down to posterity. Indeed, the schools of Italy seem to have been the only accessible sources of practical anatomy at that period: in France and England an antipathy to dissection prevailed, which was fatal to all anatomical improvement. Cortesius, who wrote at the beginning of the seventeenth century, and who, after having been professor of anatomy at Bologna, filled the chair of medicine at Massana, complains that he was prevented finishing a treatise on Practical Anatomy, in consequence of having only been able twice to dissect a human body in the course of twenty-four years, "whereas in the academies of Italy there is that opportunity once every year."

About this time the name of the renowned Harvey becomes conspicuous in the annals of anatomy: he, like his most eminent contemporaries, studied medicine in Italy. Fabricius ab Aquapendente, who was his master, had just made the highly important discovery of the valves of the veins; and it was this which, probably, more especially directed Harvey's attention to the use of the heart, and the vascular system: for at that time the liver was considered as its great centre, and the veins were supposed to convey the blood from it to the remote parts of the body. Harvey's great discovery of the circulation of the blood was taught by him in his lectures as early as 1616, though not published till 1628, in consequence of his desire to demonstrate the subject in detail, and to collect proofs and illustrations of the correctness of his doctrines. This discovery was not only of vast intrinsic importance, but, as is the case in all similar instances, it led to others; and the route of the blood had no sooner been traced and described, than the manner in which the nutritious part of the food is conveyed into the circulation became an object of research: this was successfully developed by Asellius, an Italian physician, in the year 1627. He was so fortunate as to see the lacteals filled with chyle, and to trace them to their common trunk, the thoracic duct, and thence into the blood-vessels. The lymphatic system was also soon afterwards detected, and first described by T. Bartoline, a Danish anatomist; and this was followed by important details bearing upon the anatomy of the gravid uterus and of the generative system, in which nearly all the celebrated anatomists of Europe had a share; and among them Harvey was conspicuous, though Dr. Hunter attributes, with apparent injustice, his knowledge upon this subject, and even the merit of detecting the use of the arteries, to his master Fabricius. The physiology of generation was more especially followed up by Swammerdam, Malpighi, and Leuenhoek, who were enabled greatly to extend the bounds of anatomical knowledge by their ingenious use of the microscope.

Although this country has produced many celebrated anatomists, there is no one to whom we are so deeply indebted as Dr. William Hunter, who was born in 1718, at Kilbride, in Lanarkshire, and was contemporary with the celebrated Cullen. Dr. Hunter came to London in 1741, bringing with him an introduction to Dr. Douglas, who was then engaged in a work upon the bones, and was in search of a young man who might assist in his dissections. He found in William Hunter a person so exactly suited to his purpose, that he not only engaged him as an assistant, but received him into his family and made him his son's tutor. As our object here is to give a brief historical Outline of Anatomy, rather than the biography of its successful cultivators, we must pass over many interesting points in Dr. Hunter's early history, till he came before the public as an anatomist, which was in the year 1743, when he communicated to the Royal Society an Essay "On the Structure and Diseases of Articulating Cartilages;" and was remarked for his diligence, ingenuity, and skill in the arrangement of anatomical preparations, of which he had accumulated a considerable collection, with a view of pursuing his favourite object, namely, that of publicly teaching anatomy. He commenced this arduous task in 1746, under the auspices of Mr. Sharpe, of Covent Garden, in whose theatre he made his first appearance as a public lecturer. In 1747 he became a member of the Corporation of Surgeons; and in the spring of the following year, having concluded his course of lectures, he accompanied his pupil, Mr. James Douglas, into Holland and France. He returned in time to begin his winter course, during which he not only acquired a high character as an anatomist, but commenced the practice of midwifery, in which he soon attained eminence, founded not merely upon his person and address, both of which were agreeable and well suited to that line of the profession, but upon his anatomical skill; so that in all cases of danger and difficulty it soon became customary to call in his aid. In this respect his celebrity became so extended, that he afterwards acquired great

and merited reputation as a general anatomical physician. In 1762 Dr. Hunter entered into a spirited vindication of his claims to certain anatomical discoveries, in a work entitled "Medical Commentaries;" and in the same year he was appointed physician to the queen of George III. His professional avocations now became so numerous and urgent, that he was obliged to take a partner in his lectures, and for that purpose selected his pupil, William Hewson, who afterwards joined Mr. Cruickshank, two gentlemen whose names occupy no unimportant place in the history of practical and structural anatomy.

In 1754 Dr. Hunter began his great and splendid work on the "Anatomy of the Gravid Uterus," which was not completed till 1775. This gave him a high rank among European anatomists, and foreign and domestic honours were abundantly conferred upon him in consequence; but it is to the establishment of his Museum, and School, that we are principally to look for the new impulse which was given to the study of anatomy in London, and for the celebrity which this metropolis has since maintained. The account of the origin and progress of this Museum, therefore, deserves to be briefly recorded here. When Dr. Hunter had acquired a competent fortune, the result entirely of his high professional merit and unwearied diligence, he found wealth still pouring in upon him, and became desirous of applying this surplus to some great national purpose of public utility; and what more important or useful than "A Metropolitan School of Anatomy?" He accordingly, in the year 1765, during the administration of Mr. Grenville, presented a memorial to that minister, in which he requested the grant of an unemployed piece of ground near the King's Mews, at Charing Cross, for the site of his intended building; upon which he undertook to expend 7000*l.* and to endow a professorship of anatomy in perpetuity. After waiting for some time without a reply, he renewed his request, or rather repeated his proposal; and his second application, which was even in more liberal terms than the former, shared the same supercilious treatment. Although disgusted, as he well might be, at this unaccountable neglect, he determined that the town in which he had acquired his wealth and reputation should not be without some useful and honourable memorial of his labours: he accordingly purchased a piece of ground in Great Windmill Street, near the Haymarket, where he erected a spacious dwelling-house, behind which was a magnificent fire-proof room, fitted up as a museum and library, and communicating with a good anatomical theatre, and an extensive series of apartments for dissection and for the preparation of anatomical specimens. This building was completed in 1770.

Dr. Hunter expended upon this Museum a sum exceeding 20,000*l.*: it included, besides its unrivalled anatomical treasures, a splendid and valuable collection of books, coins, medals, and antiquities; of minerals, shells, and other articles of natural history. By his will, the use of this Museum, under the direction of trustees, devolved upon his nephew, Dr. Matthew Baillie; and in case of his death, to Mr. Cruickshank, for the term of thirty years; at the end of which period the entire collection was bequeathed to the University of Glasgow, together ith a sum of 8000*l.* for its preservation. Dr. Hunter died on the 20th of March, 1783; so that his will, in regard to his Museum, has long since been carried into effect, and it is now in Glasgow. To say nothing of the books, antiquities, and objects of natural history, it contained, when sent to its final destination, the finest series of anatomical specimens in Europe. Thus, through the apathy of the administration of that day, was this unrivalled collection lost to this metropolis. Dr. Hunter's munificent intentions must, however, never be forgotten: he furnishes a noble and rare example of a man who, as soon as he had rendered himself independent by his own exertion, in a laborious and difficult profession, applied the whole of his large income to a great public object; and, though thwarted in his original desire, that it should remain in the metropolis in which the fortune expended upon it had been amassed, as a monument of his gratitude, and an example to his successors, he was, nevertheless, sufficiently liberal and patriotic to devote it to the use of the public, by bequeathing it to the university which had granted him his degree.

Dr. Hunter not only gave a new impulse to anatomical science, the effects of which have been transmitted to the present time, but his zeal in behalf of his favourite pursuit tended to make many converts. Among these, the celebrated John Hunter stands foremost. Hearing of his brother's reputation, he offered his services as an assistant in his inquiries, and his proposal was kindly accepted. Accordingly, in September, 1748, he left Lanarkshire, being then twenty years of age. His disposition to excel in anatomical pursuits soon became evident. In the course of the succeeding year he had rendered himself sufficiently master of the subject to instruct his brother's pupils in the dissecting-room; and in 1755 was admitted to a partnership in the lectures. His ardour and enthusiasm as an anatomist were most extraordinary, and he became as eminent in surgery as his brother was in physic; yet his more lucrative professional avocations were never allowed to supersede his scientific zeal; and the result was, the formation of a Museum of Comparative Anatomy, which is at once a memorial of a scientific mind and a skilful hand. Mr. Hunter died suddenly on the 16th of October, 1793, at the age of 65. He directed by his will that his Museum, upon which he had expended nearly the whole of his large professional income, should be offered to the purchase of government; and, fortunately for the credit of our country, the proposal met with a very different reception to that which we have above recorded in reference to his brother. It was purchased for the sum of 15,000*l.*, and made over, under certain conditions, which have been not only faithfully, but liberally, fulfilled, to the Royal College of Surgeons, in London. It is one of the most splendid collections in the world, and in many respects unrivalled; it is open, under proper regulations, to public inspection, in the magnificent building erected by the College for its reception, on the south side of Lincoln's Inn Fields.

Another convert to anatomical pursuits, educated in the school of William Hunter, was his nephew, the late Matthew Baillie. His virtues and his talents placed him high in public estimation; his anatomical knowledge was the foundation of his professional eminence; and the excellence of his lectures, both as regards matter and manner, tended to exalt the reputation of his uncle's school, and to establish the importance of anatomy as the basis of medical, no less than of surgical practice.

We have dwelt upon the Hunterian School, from the conviction that it gave a character to anatomical pursuits, which has materially and beneficially influenced their subsequent progress, not only in London, but throughout the kingdom. Their importance and their necessity as the basis of the sciences of medicine and surgery are now publicly felt and acknowledged; the aversion to the dissection of the human body is on the wane; and the degrading and disgraceful practice of allowing the schools of anatomy to be supplied with subjects for dissection, by the revolting process of exhumation, has been superseded.

Human anatomy is usually subdivided into *descriptive*, and *morbid*, or, more correctly, *pathological.*

Descriptive Anatomy embraces a description of the different organs of the body, together with their relative situations and connections; it examines the textures of which they are formed, enumerates the nerves and vessels by which they are supplied, and gives all general and particular details concerning their organisation. Having done this, it proceeds to the analogies that subsist among the materials of which different organs are composed; and is thus led to specify the proximate constituent parts of the living body.

Morbid or *Pathological Anatomy* comprehends all that relates to the effects of disease upon healthy structures; and carefully traces and describes the changes of texture and of composition which they thus suffer, in reference to the entire organ, as well as to its individual parts.

We shall now proceed to give a short description of the parts of which the human body is constructed, referring for the account of individual organs to the separate terms under which they are enumerated.

Anatomical teachers generally first direct the student's attention to that branch of the subject which is termed *Osteology;* in other words, to the bones or skeleton, constituting the hardest and most durable part of the whole structure, and that which gives it its stability and general form. At the period of birth, the bones, for obvious reasons, could not exist with the degree of induration and firmness which they possess in the adult; we accordingly find that, at that period, they are mostly soft and flexible, resembling cartilage, with certain specks of osseous matter, which gradually extend and increase, as the process of ossification advances during the growth of the young animal. In contemplating this bony skeleton when it has thus become perfect, we are struck with the admirable adaptation and mutual connection of the various parts of which it consists; the separate bones being extremely numerous, (including the teeth, amounting to about 250,) and attached to each other by unequal surfaces, the cavities and eminences of which mutually correspond. These connections, termed *articulations*, are extremely various; some admitting of every variety of motion, others of limited motion, and others, as it were, continuously united. In the former case the evils of friction are perfectly provided against by the peculiarity of the articulating surfaces, which are covered with an extremely smooth and elastic substance, called *cartilage;* and lubricated, or as it were oiled, by a slippery fluid termed *synovia*, which here performs precisely the same office as that of the various anti-attritions which are used in machinery. But as the bones must be more or less restricted in their range of motion, there are peculiar means by which that end is attained: some being prevented from changing their relative situations by certain

modes of articulation; others, where a slight motion is required, being united by cartilage; and others, where extensive and varied motions are wanted, being connected by ligaments, membranes, or flesh.—*Ligaments* are white, fibrous, glistening, and flexible substances, occurring in an infinite variety of forms and situations. They are, for the most part, exterior to the joint, and, by their great strength and trifling elasticity, preserve the relative position or connection of the bones in their various movements. — *Membranes* are thin, whitish webs or textures, more flexible and elastic than ligament. They not only assist in the security and motion of joints, but fulfil a variety of other offices. They surround or line the cavities and the organs of the body, and contribute to unite and combine the whole; and, at the same time, interpose, and preserve a distinction, enabling separate parts either to co-operate or to act independently of each other. They vary in strength and texture, and different terms are applied to them in different parts of the body: two within the skull are called *matres;* those which envelope muscular fibres are called *aponeuroses;* that which covers the lungs and lines the cavity of the chest is termed *pleura;* that which lines the cavity of the abdomen and its included viscera is named *peritoneum;* those which inclose articular surfaces are termed *capsules;* that which covers bone, *periosteum;* and, in other cases, they are called *coats*, or *tunics*. The remaining substance concerned in the connection of the bones is *flesh:* it is thus, that the upper extremities are connected with the body, and that many of the joints are rendered secure. But flesh performs another and more important office, inasmuch as it constitutes a principal part of the organs termed *muscles*, through the medium of which the various movements of the body are effected. Many of the muscles contain, besides flesh, a substance analogous to ligament, through the medium of which they are attached to the bones, and to which the term *tendon* is applied: muscles and tendons are composed of bundles of fibres, which may be unravelled to extreme minuteness; and when what appears to be a single fibre is viewed under the microscope, it resembles a chain of infinitely small globular particles. But though the muscles are the immediate organs of motion, they are dependent for their powers of contraction and relaxation upon the *nerves* with which they are supplied. These, when separately examined, appear in the form of white cords or threads; and, when traced to their origin, are found to issue as it were from the brain, and from its elongation, termed the *spinal marrow*. The trunks of the nerves are subdivided into branches, and these again into filaments, which enter into, and are, as it were, lost in the substance of the muscles and other organs of the body. Their functions are in some cases obedient to, and in others independent of the will: to the former belong the nerves of the locomotive muscles; to the latter, those of the heart, viscera, &c. When they are divided, the peculiar functions of the organs which they supply are impaired or impeded: thus, the muscles may be deprived of the power of contracting, the glands of secretion, the eye of sight, the ear of hearing, and the skin of feeling. The nervous trunks, which issue in pairs from the brain or spinal marrow, amount to about forty; and in tracing them and their branches, they are found in certain different places to swell into knots, which are termed *gangliæ*, or they are reticularly aggregated into *plexuses*.

Having thus shown how the bones are connected and put into motion, and from what sources their motion is derived, it may next be inquired how they and the other organs of the body grow and are nourished. This brings us to consider the blood and its vessels.

The composition and properties of the blood, and the extraordinary changes which it suffers in its passage through the pulmonary vessels, are elsewhere defined. (*See* Blood, and Respiration.) Without this exposure to the action of the air in the lungs, the blood is unfit for the support of life. We accordingly find that the heart is so constructed as to propel the blood which it receives through the structure of the lungs, and after it has there been aërated, to transmit it over the body: in fact, the heart is a hollow muscle: when it relaxes, its two principal cavities, or ventricles, are enlarged, and the blood flows in; when it contracts, they are diminished, and the blood is propelled into two large tubes or arteries, one leading to the lungs, and called the pulmonary artery, and the other to the system generally, and called the aorta: these arteries are not only elastic, but also muscular, so that they drive the blood onwards from the heart, its retrograde motion being effectually prevented by valves placed at their origin.

The arteries are divided and subdivided into an infinite number of ramifications; and the branches from the same trunk are frequently observed to unite or anastomose in their course; so that when, by any accident, some are obstructed, an adequate supply of blood may be kept up by the others. As, however, the blood cannot return to the heart by these vessels or arteries, we find that they inosculate, or communicate at their extremities with another series of tubes or vessels, which are called veins. These are more numerous than the arteries, and generally accompany them in their course. They have a less muscular power; and as they are not assisted by the heart in propelling the blood, they open to it larger and larger channels as it advances, and are supplied with valves by which its reflux is prevented. This is, in fact, the circulation of the blood (first made out by Harvey, as before mentioned); the veins ultimately terminating in two large trunks which pour the blood into the right auricle of the heart; whence it is propelled into the right ventricle, from which arises the pulmonary artery, transmitting it through the lungs; from the lungs the blood (having been aërated) returns by the pulmonary vein into the left auricle of the heart, which contracting, propels it into the left ventricle, from which arises the aorta. Such, then is the extraordinary mechanism by which the circulation of the blood is effected; but it must not be supposed that the whole of the blood is thus directly returned from the arterial into the venous system: a part of it is transmitted by minute arterial ramifications into the different structures and organs of which the body is composed, each of which is gifted with the power of assimilation, that is, of converting the blood, or a part of it, into a substance of its own kind. Some of these minute or capillary vessels also terminate upon the surface of the body, where they exhale perspirable matter; others, upon the membranes lining the cavities of the body, where they secrete the fluids which lubricate and moisten the interior surfaces; and others again go to the glands, —those peculiar organs or structures, which have not only the power of separating certain parts of the blood, but of converting it into new forms, which are called secretions, some of which are ejected, others retained, for the purposes of the animal economy.

Thus, then, it appears that the blood nourishes and preserves the body and all its parts, and that it is continually tending to the renovation and reproduction of the different organs; but this very process implies another, and no less extraordinary, function, which is performed by a distinct system; namely, that of absorption. There are, in short, a series of vessels which are continually carrying away the useless and worn-out materials; removing them in a state of solution; furnished, like the veins, with valves; terminating in a common trunk, called the thoracic duct; and pouring its contents into the veins, just before they enter the right auricle of the heart.

It appears, therefore, that a continual system of deposition and removal is carrying on within the living body; that the ramifications of the arterial system are constantly renovating the different organs, whilst the absorbents are as constantly removing the materials of which they consist. Nothing, therefore, is stationary or permanent; and as the blood, on the one hand, conveys the materials required, so, on the other, it receives those which are removed: and such as are useless, or would be hurtful if retained, are thrown off either by the intestines, the kidneys, the lungs, or the skin. It now only remains to show how this waste is compensated for, and by what means those materials which are thrown off in one form are replaced in another: this leads us to the functions of another branch of the animal machinery, called the organs of digestion; those organs, namely, by which the food is converted into blood.

Different animals require different kinds and quantities of food; some living almost exclusively upon animal, others upon vegetable substances; hence their division into carnivorous and graminivorous tribes. Man partakes of both; and, accordingly, the structure of his digestive organs is intermediate between the comparative simplicity of the truly carnivorous, and the complexity of the graminivorous classes. In all the higher orders of animals, however, the mechanism of digestion is of a complicated character.

The first change which the food undergoes is in the mouth, where it is torn, ground, and moistened by machinery expressly adapted to those operations. The teeth are admirably contrived for this purpose; some of them cutting, and as it were mincing, others rubbing and grinding, whilst a fluid is supplied by the salivary glands so as to render the mixture of a proper consistency to be swallowed: this is effected by the organs of deglutition: the food is propelled from the mouth into the tube which conveys it to the stomach, and which is called the œsophagus; and is, at the same time, prevented, by an extraordinary and complicated arrangement of the parts concerned, from passing in any other direction, and, more especially from entering the trachea or air-passage into the lungs. In the stomach the food is subjected to the secretions of that organ, called gastric juice, which is acid, and by which it is gradually converted into a greyish homogeneous semi-fluid substance, termed chyme; so that by the time the food has reached the right end of the stomach, or the pylorus, its original characters are entirely changed; its separate materials are no longer discernible, and it has acquired distinct properties; it is, in short,

digested. How these changes are effected we know not, though many attempts have been made to explain them upon chemical and mechanical principles. Dr. Hunter, in his Introductory Lecture, has the following apposite remarks, in reference to this and similar phenomena, "I must therefore expect," he says, "that you will not hereafter be surprised, when you find me avowing great ignorance in many of the most considerable questions relating to animal operations, such as sensation, motion, respiration, digestion, generation, &c. In my opinion, all these subjects are much less understood than most people think them. Our vanity deceives us, and persuades us that we have got the whole as soon as we have acquired a smattering of natural knowledge. Hence it is that the different sects of physiologists have endeavoured to explain animal functions upon such different principles. Hence, for example, to account for digestion, some have made the stomach a mill; some would have it to be a stewing-pot, and some a wort-trough; yet, all the while, one would have thought that it must have been very evident that the stomach was neither a mill, nor a stewing-pot, nor a wort-trough, nor any thing but a *stomach.*"

When the food has been thus far digested in the stomach, it passes into the duodenum, or upper end of the intestinal canal; a tube, the whole length of which is about six times that of the body, and which, therefore, is variously and strangely convoluted to enable it to be packed into the abdominal cavity. Into this portion of the intestines, various vessels and glands deliver their secretions, partly for the purpose of lubricating its surface, and partly to assist in the further changes which are to be brought about in the chyme. Of these fluids, two are especially remarkable, from the importance and size of the glands by which they are secreted, and of the ducts by which they are conveyed; namely, the *bile*, which is of a green colour and bitter taste, and is secreted in the liver; and the *pancreatic juice*, which appears to resemble saliva, and which is secreted by a gland called the pancreas. The influence of these fluids upon the chyme is direct and important: the pancreatic secretion probably acts as a diluent merely; but the effect of the bile is more complicated; and it appears to be essential to the further change of the chyme into *chyle*, which is a white milk-like fluid, formed in the upper part of the intestine, and absorbed by a distinct set of vessels which, from the colour of their contents, have been called lacteals, and which convey the chyle, that is, the portion of the products of digestion fitted for nutrition, into the above-mentioned trunk of the lymphatics, whence it is transmitted into the veins, which open through the medium of the right auricle into the right ventricle of the heart. The bitter principle of the bile, and its colouring matter, are obviously not absorbed by the lacteals, but remain with the residue of the food, which is slowly propelled along the whole of the intestinal tube, and, having undergone certain changes in its passage, is ultimately voided as excrementitious.

Having now enumerated the various classes of organs in the human body, and adverted to their leading functions; having seen how the bones are united by articulations, and connected by ligaments, flesh, and membranes, forming a variety of levers adapted to the motions of the limbs, and supporting and protecting the soft parts, as in the skull and spine; how the brain and nerves are concerned in the sentient energies, and in presiding over and directing muscular motion, and influencing the functions of the viscera; having likewise seen how each part of the body is nourished by the blood, which is sent from the heart by the arteries, and conveyed back to it by the veins; how the useless and decayed parts are removed by the lymphatics; how the nutritious part of the food is carried into the blood by the lacteals; and how venous is changed into arterial blood in the course of its passage through the pulmonary vessels; it only remains to observe, that the whole fabric is as it were protected from external injuries by its *integuments.* Of these the most exterior is a covering, varying in thickness and induration on different parts of the body, but every where without feeling, and called the *epidermis;* immediately beneath it is a soft mucous substance termed *rete mucosum;* and under it the *cutis*, or true skin. These external coverings of the body are attached to and connected with the parts beneath, by cellular membrane. But though the animal owes much of its general security to these textures, it owes more to the senses, instincts, and appetites, with which it is so miraculously endowed. "By these it is led to pursue what is useful, and to guard against danger, inconvenience, and want. Nor is this all; there has likewise been conferred, to a certain extent, upon all living bodies, the power of reproduction, by which they are frequently able to repair the slighter injuries to which the different organs are exposed; and if this power be exceedingly languid in the latter periods of old age, it is because the author of nature never intended that the animal structure should be immortal. He has fixed its bounds, which it cannot pass; and has measured out the time when the fairest fabric must crumble into dust, and its animating spirit return unto Him, the great Almighty Incomprehensible Being, who first bestowed it." (See Dr. Barclay's Introductory Lectures to a Course of Anatomy; and Dr. William Hunter's Two Introductory Lectures, for details respecting the history, uses, and importance of the study of Anatomy.)

Anatomy, Comparative. So called because the organisation of the lower animals was first principally studied with immediate reference to that of the human subject. Galen, who visited the schools of Alexandria at a period when the dissection of the human body was no longer permitted, sought in the anatomy of the ape to acquire a vicarious knowledge of the anatomy of man. Vesalius, after the revival of literature, dissected various quadrupeds, and compared their organisation with that of man, in order to correct the errors of Galen, and to establish the true knowledge of the peculiarities of the human structure.

Succeeding anatomists have investigated the structure of the lower animals, to acquire the knowledge necessary for experimenting upon them with success; and still more important discoveries in physiological science have resulted from tracing the modification and disappearance of different organs in the descending series of animals, as the only means by which we can obtain just notions of the uses and relative importance of the different organs in the animal economy, and a perception of the laws which regulate their co-existence in the same individual.

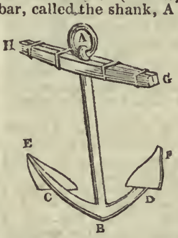
Aristotle, Harvey, and Hunter combined the investigation of the mature animals of different classes with observations of the different stages of development of the embryo, and their example has been assiduously and successfully followed by the ablest comparative anatomists of the present day, whereby some of the general laws of animal organisation, of development, and of the analogies which apparently different parts bear to one another throughout the great scheme, have been discovered.

A very important application of comparative anatomy is to the determination of the relative degrees of complexity in the organisation of different animals, and of the number and value of the points of resemblance which different species manifest to each other in the totality of their organisation. A study of the anatomy of animals, guided by these views, is essential to the determination of their natural affinities, which is the highest aim of the philosophic naturalist.

Lastly, the labours of the comparative anatomist continually tend to bring to light examples of structures, designed with reference to especial purposes, of the most striking and forcible description; and thus provide for the moralist and divine a storehouse of facts peculiarly adapted to the illustration of the doctrine of final causes.

ANA'TROPOUS. (Gr. ἀνατρέπω, *I invert.*) A very common kind of embryo, produced by one side of the ovule growing upon itself, while the other remains immoveable, till, at last, that part of the ovule which was originally next the apex, is brought down to the hilum, the base of the nucleus in such cases being at the apex of the ovule. The common apple, and the greater part of plants, offer an example of this.

A'NCHOR. (Gr. ἀγκυρα.) Consists of a straight bar, called the shank, A B, which ends in two arms, B C, B D, on which are placed the triangular plates called flukes, or palms; the extremity E or F is called the pea (peak) or bill; the point B is called the crown. At the end A is placed the stock G H, which, when of wood, consists of two pieces of oak, hooped together. When the stock is of iron, it passes through a hole in the end of the shank. The stock is at right angles to the plane of the flukes, and is a little longer than the shank. At A is the ring, which is of iron, to which the cable is attached, and by which the anchor is lifted or hung.



When a hemp cable is used, the ring to which it is bent (fastened in a particular way) is covered first with tarred canvas, and then with pieces of rope secured firmly round it; this is called a puddening, and protects the hemp from the iron. When a chain cable is used, it is shackled to the ring, which is not then puddened.

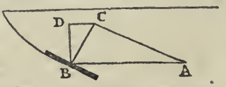
Men of war and large ships carry two large anchors of equal size, at the bows, called, thence, bower anchors; and two others, of the same size, called the sheet and the spare anchors; besides two or three others, which are much smaller, for temporary occasions.

The anchor, after being let go from the ship's bow or side, whether the shank be vertical or horizontal when it enters the water, arrives upright at the bottom, in consequence of the resistance of the water on the stock,

when it falls over, and rests on the crown, one corner of a fluke, and the end of the stock. From this position of stable equilibrium on three points, forming a long narrow triangle, a small force disturbs it, when the stock, falling flat, one of the bills must pierce the ground, penetrating deeper as the cable pulls, until the arm is partly or entirely buried.

Since the security of the vessel depends on the hold the anchor has of the ground, it is evident that the direction of the fluke should be such that the reaction of the soil against it, from the pull of the cable, may tend most effectually to keep it down.

The pressure on the fluke being perpendicular to the surface, take AB to represent the pull of the cable, then the resolved portion of this perpendicular to the fluke is BC or $AB \cos. ABC$; and the effect of this in keeping the fluke down is $BD = BC \cos. CBD = BC \sin. ABC$, because AB is horizontal, and CBD is $90^\circ - CBA$, vertical; hence $BD = AB \sin. ABC \cos. ABC$, which is maximum when $ABC = 45^\circ$. The flukes of anchors in general make the angle with the shank much greater than this; but Lieut. Rodger, R. N., has, among other improvements, adopted this angle in his patent anchor, having established the above conclusion by experiment.



Anchors are made of broad flat bars forged together. As the greatest strain upon the shank takes place during the act of weighing, the diameters of the shank are made unequal, the longest being placed vertical. This improvement is, we believe, due to Mr. Pering, on whose plan anchors have of late years chiefly been made.

The weight of an anchor in men of war is estimated roughly at about 1 cwt. to a gun; in merchantmen, about 1 cwt. for each 15 tons. The weight of the anchor is not strictly proportional to the size of the vessel, as large vessels are less affected by sudden or violent motions than smaller ones are. Large anchors are thicker in proportion to their length than smaller ones are; that is, the weight increases faster than the cubes of the dimensions.

When an anchor is left behind, it is recovered either by lifting it by the buoy rope, or, where that is not possible, by sweeping for it; which is dragging a hawser, hung between two boats, slowly over the bottom till it catches the upper fluke, by which the anchor is then weighed.

When one anchor is down the ship is said to be at single anchor, when two are down, the ship is generally moored. (*See* Moored; Cable; Buoy.) Ships rarely ride by more than two anchors; in bad weather a third is often let go under foot, as a precaution in case of one of the cables parting.

When the anchor is dragged by the pulling of the cable, it is said to come home. When the cable gets twisted round the anchor or stock, the anchor is said to be foul. The anchor is sometimes hove up without one of the flukes, which has either been fixed in a cleft of the rock and wrenched off by the force of weighing, or been snapped off, as some think, by striking against a point of rock in its rapid descent.

When the ship is at single anchor, the wind or tide may carry her over the anchor; if the water is deep, she may so drag the cable as to foul the anchor, in which case it may not hold again; if the water is very shallow, she may get upon the anchor, the fluke entering the ship's bottom, or she may break the shank by striking upon it. Keeping the ship clear of her anchor is, therefore, an important, as it is also a nice point of seamanship.

When the anchor is lifted out of the ground, it is said to be aweigh; when hove up to the surface of the water, it is awash. The anchor being hove up by the cable only to the hause holes, is lifted by the ring to the cathead; this is called catting it. The fluke next the ship's side is then lifted up to its resting-place, called the bill board; it is now said to be fished. When the ship is fairly at sea, the ring is lashed close up to the cathead, and the fluke brought close to the ship's side, or inside the bulwark, and the cable and buoy rope unbent; the anchor is then secured.

Anchor. In Architecture, an ornament applied to mouldings somewhat resembling an anchor intermixed with eggs, and by some called a tongue, from the resemblance it bears to the forked tongue of a serpent. It is found in the mouldings of all the orders, but is only applied to that called the echinus or quarter round.

A'NCHORAGE. Ground fit to hold a ship's anchor, so that she may ride safely. The ground best suited for this purpose is hard sand, or stiff clay; and the best position is that which is land-locked, or out of the tide.

AN'CHORITE. (Lat. anachoreta. Gr. ἀναχωρεω, *I retreat*, or *withdraw*.) More properly, anachoret, a hermit, or person who has retired from the world with the purpose of devoting himself entirely to meditation and prayer. Such was the case with many of the early Christians, beginning, perhaps, with such as fled from the persecutions of Decius and Diocletian, and retired into forests and deserts, at first with a view to security merely, and afterwards continued, from religious motives, the mode of life they had there adopted. The adoption of perfect solitude was essential to the character of an anchorite: but they were not necessarily bound by vows. The origin of this class of religionists preceded that of the Cœnobites, or monks living in societies; but in later times the monks used frequently to leave their monasteries, with the permission of their superior, and devote themselves for a time, or for their whole lives, to the solitude of anchorites.

ANCHO'VY. *See* Engraulis.

ANCHYLO'SIS. (Gr. ἀγκυλοω, *I bend.*) A stiff, immoveable, or bent joint.

A'NCIENT DEMESNE. In Law, all lands which, having been in possession of Edward the Confessor, and from him having passed to William the Conqueror, are named in Doomsday Book as Terra Regis, are said to be held in ancient demesne. The tenure is peculiar, resembling copyhold in some respects.

A'NCIENTS. (Fr. anciens.) In the more general sense of the term, Ancients means those who lived long ago, or before the *moderns*. But the term is now usually employed to designate the Greeks and Romans; and if any other people be meant, it is customary to specify them, as the ancient Germans, the ancient Jews, &c.

Ancients, Council of. In French History, one of the two assemblies composing the legislative body in 1795. It consisted of 250 members; and derived its name from each of them being at least forty years of age. It was put an end to by the Revolution of the 18th *Brumaire*.

ANCI'LE. The shield of Mars, which, according to tradition, fell from heaven in the reign of Numa, and was accompanied by an oracle, which declared that, while it remained in Rome, the city could never be taken. Its figure was that of an oval compressed in the middle, so as to be widest near the two extremities. Numa had it preserved in the temple of Mars, to whose priests, the Salii, its care was committed; and at the same time had eleven more shields made to exactly the same pattern, in order to prevent the genuine one from being distinguished and stolen.

Every year, in the month of March, these ancilia were carried round the city by the Salii, with solemn dances and music, for thirty consecutive days, during which time no business connected with war was allowed to be carried on in the city.

ANCI'PITAL. Having two opposite edges or angles.

ANCI'PITOUS. (Lat. anceps, *two-edged*.) When any thing is compressed, with the two opposite edges thin. It is chiefly applied in Botany to leaves and stems.

ANCO'NES. (Gr. ἀγκων, *the point of the elbow*.) In Architecture, the consoles or ornaments cut on the keystones of arches, or on the side of door-cases. They are sometimes used to support busts or other figures.

ANDALU'SITE. A mineral composed of 52 alumina, 58 silica, 8 potass, 2 oxide of iron. It is very hard and infusible, by which characters it is distinguished from felspar. It was first observed in Andalusia in Spain.

ANDA'NTE. (Ital. *going*.) In Music, signifies that the notes are to be played distinctly.

ANDRÆA'CEÆ. (Andræa, one of the genera.) Little moss-like plants, differing from the mosses in the want of an operculum and peristome, and in having a four-valved theca.

A'NDREASBE'RGOLITE. From Andreasberg, in the Hartz. A mineralogical name of a species of Harmotome.

ANDRE'NA. The name of a Fabrician genus of bees, including those which have the tongue 3-cleft, and the labium cylindrical, with two membraneous bristles on each side.

ANDROCÆ'UM. (Gr. ἀνηρ, *a male*, and οἶκος, *a house*.) All that part of a flower to which the male organs appertain. The ring of stamens in a plant is an androcæum; so is the fringe at the mouth of the tube in the passion flower, taken together with the true stamens. The term may be literally translated the male apparatus.

ANDRO'GYNOUS. (Gr. ἀνηρ, *a man*, and γυνη, *a woman*.) An animal whch possesses the organs of both sexes, as the snail. An hermaphrodite.

In Physiology, the possession of the organs of both sexes in the same individual, either naturally, as in the snail; or preternaturally, as in the free martin and similar monsters. An hermaphrodite.

In Botany, a union of both males and females, either in the same flower, which is also called hermaphrodite; or upon the same plant, the sexes being in different flowers, as in the birch and similar trees. The latter is what Linnæus called monœcious.

A'NDRON. (Gr. ἀνηρ, *a man*.) In Grecian and Roman Architecture, the apartment appropriated to the reception of the male branches of the establishment, and always in the lower part of the house: the gynœcea, or women's apartments, being in the upper part.

ANDROPE'TALOUS. (Gr. ἀνηρ, *a man*, and πεταλον, *a petal.*) Is used in speaking of double flowers which are produced by the conversion of the stamens into petals, as the garden ranunculus. Most double flowers are of this nature.

ANDRO'PHORUM. (Gr. ἀνηρ, *a man*, or, in Botany, *a stamen*, and φερειν, *to bear.*) A columnar expansion of the centre of the flower, on which the stamens seem to grow, as in the passion flower. In reality, it is formed partly of the adhering filaments, and partly of an elevation of the growing point.

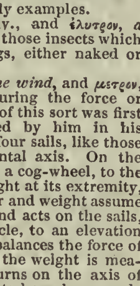
A'NECDOTE. (Gr. ἀνεκδοτον, *something inedited*, or *unpublished.*) In its original sense, some particular relative to a subject to which publicity had not been given in previous works on that subject. In its secondary sense, the narrative of a particular action or saying of an individual.

ANE'LLIDES, ANELLA'TA. (Lat. anellus, *a little ring.*) Generally, but improperly, written Annelidans or Annelides. A class of articulate animals with a long cylindrical body divided into ring-like segments, having red blood, and respiratory organs, but no jointed extremities. The class is divided, according to modifications of the respiratory system, into, Cephalobranchiates, Dorsibranchiates, and Abranchiates, of which the *Serpula*, or tube-worm, the *Aphrodita*, or sea-mouse and the *Lumbricus*, or earth-worm, are respectively examples.

ANELY'TROUS. (Gr. ἀ, priv., and ἐλυτρον, *a sheath.*) A name sometimes given to those insects which have two or four membranous wings, either naked or covered only with hairs or scales.

ANEMO'METER. (Gr. ἀνεμος, *the wind*, and μετρον, *measure.*) An instrument for measuring the force or velocity of the wind. An instrument of this sort was first invented by Wolfius, and described by him in his *Elementa Metheseos*. It consists of four sails, like those of a windmill, turning on a horizontal axis. On the axis is a perpetual screw, which turns a cog-wheel, to the axis of which a lever, carrying a weight at its extremity, is attached. When it is calm, the lever and weight assume the vertical position. When the wind acts on the sails, the lever is raised in a vertical circle, to an elevation at which the weight exactly counterbalances the force of the wind. The angle of elevation of the weight is measured on a dial, the index of which turns on the axis of the cog-wheel. Several improvements have been made on this form of the instrument. The sails have sometimes been placed horizontally; and Mr. Benjamin Martin gave the axis the form of the fusee of a watch, having a cord winding upon it with two weights at the ends, which answers the same purpose as the lever and weight.

Dr. Lind's anemometer consists of a glass tube, bent into the form of the letter U, and open at both extremities. One of the extremities, A, is also bent round to the horizontal direction, in order that the wind may blow into it. The tube being partially filled with water and exposed to a current of air, the water in the branch at which the wind enters is depressed, for example, to B, and consequently rises in the other branch to C, and the difference at C, of the levels at which it stands in the two branches, is the height of a column of water, the weight of which forms a counterpoise to the force of the wind. The relative velocities of the wind are thus ascertained, the variation of the velocity being nearly proportional to the square root of the resistance. The bore of the tube is diminished at the bottom to check the undulations of the water caused by a sudden gust of wind. Various other contrivances have been proposed, of which one of the simplest is to expose a flat board of given dimensions to a current of wind, and observe to what extent it will force back a spring attached to it, and resting against an immoveable obstacle.



ANEMO'NIN, or ANEMO'NIA. An acrid crystallisable substance obtained from some species of anemone. It burns like camphor.

A'NEMOSCO'PE. (Gr. ἀνεμος, *wind*, and σκοπεω, *I look.*) An instrument for indicating the direction of the wind. A common vane, or weathercock, is an instrument of this kind. Sometimes the vane turns a spindle which descends through the roof of the building into the chamber where the observation is to be made. An index fixed to the spindle points out the direction of the wind, on a compass card fixed to the ceiling. By means of wheel-work, the direction of the spindle, or the axis of the index, may easily be changed, so that the compass card may be placed on a wall of the chamber, or in any convenient position for observation.

A'NEURISM. (Gr. ἀνευρυνω, *I dilate.*) A tumour formed by the morbid dilatation of an artery, and which is therefore distinguished by its pulsatory motion.

ANFRA'CTUOUS. (Lat. anfractus, *a winding backward and forward.*) When the lobes of an anther, of the margin of any thing, is folded back upon itself, and doubled and bent till all trace of its normal character is lost. The anther of a cucumber is anfractuous.

A'NGEL. A coin of the value of about ten shillings. It was impressed with the figure of an angel, in commemoration of a saying of Pope Gregory, that the pagan Angli or English were so beautiful, that if they were Christians they would be angels.

ANGEL, GOLDEN, or ST. GEORGE, or ST. CONSTANTINE. An ancient order of knighthood, fabulously reported to have been instituted by Constantine, but probably by the imperial house of Comnenus at Constantinople, and revived by the Emperor Charles V. The grand mastership of this order was resigned by the last representation to the house of Comnenus to that of Farnese, dukes of Parma; and now belongs to the crown of Naples.

ANGEL-WATER. A mixture of rose, orange-flower, and myrtle water, perfumed by musk and ambergris. It is made in Portugal.

AN'GELS. Spiritual beings ministering to God. In the Scriptures they appear as messengers, which the word properly denotes (Gr. ἀγγελος), by whom God conveys his commands to men. The term seems also to be applied to the highest order of ministers in the Church of Christ, if we may so interpret the "Angel of the Church of Ephesus, of Pergamus," &c., and the passage in the Epistle to the Corinthians, "A woman ought to have power (a veil, as some interpret) on her head, for fear of the angels." We read also of the devil and his angels.

ANGI'NA. (Gr. ἀγχω, *I strangle.*) A disease attended with a sense of anxiety and suffocation: the term is applied to sorethroat, and to certain symptoms arising from organic disease of the heart; the latter gives rise to a distressing difficulty of respiration, and is hence termed Angina Pectoris.

A'NGIOCA'RPOUS. (Gr. ἀγγειον, *a case*, and καρπος, *fruit.*) When seed-vessels are inclosed within a covering that does not form a part of themselves; as the filbert, which is covered by its husk, the acorn seated in its capsule. The word is also applied sometimes to such fungi as have their spores included in a peridium, or hollow-shell, as Lycoperdon.

ANGIO'LOGY. (Gr. ἀγγειον, *a vessel*, and λογος, *a discourse.*) The doctrine of the vessels of the body.

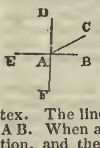
ANGIOSPE'RMOUS. (Gr. ἀγγειον, *a vessel*, and σπερμα, *seed.*) When seeds are inclosed within a pericarp, as in most plants. The word is now chiefly used in opposition to gymnospermous, when seeds are not included in a pericarp, as in fir-trees and others. Linnæus intended to apply it in the same sense; but he contrasted it with small-lobed seed-like fruits, which he mistook for naked seeds.

ANGIO'SPOROUS. (Gr. ἀγγειον, *a vessel*, and σπορα, *a seed.*) A term applied to such fungi as Lycoperdon, which have their spores inclosed in a hollow shell or bag.

ANGIO'TOMY. (Gr. ἀγγειον, *a vessel*, and τεμνω, *I cut.*) The dissection of vessels.

A'NGLE. (Lat. angulus, *corner.*) In Geometry, this term is employed in several senses, and to signify very different things. Euclid defines a plane angle to be "the inclination of two lines to one another, which meet together, but are not in the same direction;" a definition somewhat obscure, and also defective, inasmuch as in strictness it can apply only to acute angles, and gives no idea whatever of angular magnitude. The definition given by Apollonius, namely, "the collection of space about a point," is still more exceptionable. In fact, it is extremely difficult to form a correct idea of its nature from any description that can be given in the terms of a definition.

The simplest way, perhaps, of obtaining a clear conception of angular magnitude is by means of revolving motion. Suppose a straight line A B to revolve about the point A from right to left, and to occupy successively the different positions A B, A C, A D, A E, and A F. At A C it forms angle B A C with its first position A B, of which A B and A C are the sides, and the point A the summit or vertex. The line A C is then inclined to its first direction A B. When at A D, it is perpendicular to its first direction, and the angle formed by A B and A D is called right. At A E the separation is equal to two right angles, and the line lies in the same direction as at first, or A E and A B are in the same straight line. When it arrives at A F, three right angles have been described; and, on returning to A B, a whole circuit or four right angles. The right angle B A D is considered the unit of angular magnitude B A C, which is less than the right angle, is called acute; and E A C, which is greater than the right angle is called obtuse. The angle D A C, or the defect of B A C from the right angle, is called the complement of B A C; and E A C, or the defect of B A C, from two right angles, is called the supplement of B A C.



When an angle is considered in this manner as result-

ing from revolving motion, it is obvious that two straight lines meeting in a point, form not only one, but an indefinite number of angles. Thus, A B may pass into the position A C after describing merely the angle B A C, or after describing that angle together with one, two, three, or any number of revolutions. If we assume A to represent the measure of the angle B A C, and C that of the whole circuit, then the same angle B A C will be represented not only by A, but also by $A + C$, $A + 2C$, $A + 3C$, and so on. This extension of the signification of an angle is of very great importance in Trigonometry.

A solid angle is defined by Euclid to be "made by the meeting of two plane angles which are not in the same plane in one point." These magnitudes are of a very peculiar kind; and, unlike all other subjects of geometrical investigation, admit of no accurate comparison one with another. No multiple or submultiple of such angles can be taken, and we have no way of expounding, even in the simplest cases, the ratio which one of them bears to another. Hence all our reasoning concerning them must be chiefly confined to the plane angles by which they are contained.

Angle, Facial. In Zoology, signifies the angle made by the intersection of two lines drawn, the one from the most prominent part of the frontal bone over the anterior margin of the upper jaw, the other from the external orifice of the ear-passage along the floor of the nasal cavity.

Angle, Frontal. In Ornithology, signifies the angle which the culmen, or upper line of the beak, makes with the forehead.

Angle, Spherical. In Trigonometry, signifies the angle made on a sphere by the intersection of two great circles, or the inclination of the planes of these circles to each other. A spherical angle is measured by the arc of a great circle intercepted between those two points of its sides which are at the distance of a semicircle from the point of intersection, or the vertex of the angle.

Angle, Visual. (Optics.) The angle formed by two rays of light, or two straight lines drawn from the extreme points of an object to the centre of the eye. The apparent magnitude of objects depends on the magnitude of the angle under which they are seen; nevertheless, in observing distant objects, our ideas of their magnitude are greatly modified by the judgment which we form of their distances. (*See* Apparent Magnitude.)

A'NGULAR MOTION. The motion of a body moving circularly, or oscillating about a fixed point. The angular motion of a planet is measured by the angle described at the centre of the sun, by a straight line drawn from that point to the planet, called the radius vector; and its amount is reciprocally proportional to the periodic time of the planet.

A'NGULAR SECTION. The division of an angle into any number of equal parts. The bisection of an angle is accomplished by elementary geometry. The trisection requires the aid of the solid geometry, being equivalent to the solution of a cubic equation. The general division of an angle into any proposed number of equal parts, is a problem which Mathematicians have not yet been able to solve. In modern Mathematics, the term Angular Sections is used to denote that branch of analysis which is employed in the investigation of the properties of circular functions.

ANGUI'LLIFORM. (Lat. anguilla, *an eel*, forma, *shape*.) Eel-shaped fishes, or those belonging to the tribe of eels.

A'NGUIS. The name of a Linnæan genus of Amphibia serpentes, characterised by having subcaudal and abdominal imbricated scales; which scales consequently form a uniform covering over the whole body. The genus is now subdivided into the subgenera Pseudopus, Ophisaurus, Acontias, and Anguis, properly so called; the reptiles comprehended under the latter denomination have the tympanum concealed beneath the skin; the maxillary teeth compressed and hooked, and no teeth on the palate. The *Anguis fragilis*, or slow-worm, is a well-known example of this genus.

ANGUSTU'RA BARK. The bark of the Cusparia febrifuga, originally imported from Angustura in South America; it is occasionally used in medicine as a tonic, and in the case of diarrhœa. It was first described by Mr. Brande in the year 1791. A poisonous bark is occasionally found in commerce under the name of spurious Angustura, which appears to be the produce of a species of strychnos.

ANGU'STATE. (Lat. angustus, *narrow*.) When any part sensibly diminishes in breadth. (*See* Attenuated.)

ANHELA'TION. (Lat.) Difficulty of breathing.

A'NHYDRITE. An anhydrous sulphate of lime.

A'NHYDROUS. (Gr. ἀ, *without*, and ὕδωρ, *water*.) Without water. A term often applied to salts, and to certain acids when deprived of water.

A'NIL. One of the plants yielding indigo.

Anil. (Sanscr. nili, *indigo*.) A kind of indigo, said to be a native of America, although now cultivated in the East Indies. It is very like Indigofera tinctoria, the true indigo, from which it chiefly differs in having compressed legumes which are not torulose.

ANILLE'ROS. In Politics, the name given to the moderate party among the principal actors in the Spanish revolution from 1820 to 1823. They had the greatest influence, and directed the Cortes. Arguelles and Martinez de la Rosa were at their head.

A'NIMAL. (Lat. anima, *soul*, or *life*.) The name of the higher division or kingdom of organised beings, distinguished by endowments of sensation and voluntary motion, superadded to the organic functions which animals possess in common with plants.

It has been objected to this definition, that the so called sensitive plant is susceptible of impressions which cause action and motion of its parts, and that the embryos of Algæ and Confervæ have locomotion, while many of the lower animals are fixed as immoveably to the earth as plants. But these objections have no real value; and could only have arisen from confounding irritability with sensation, which are two very different phenomena. It is the property of all living organised beings, and essential to their existence as such, to be susceptible of the impressions of certain stimuli, which occasion a reaction of the part stimulated; and the main object of physiology is to determine the precise mode in which each organ of a plant or animal reacts when stimulated. But it is here only necessary to state, that the muscular fibre in animals reacts when stimulated by an angular puckering called contraction, and this property is termed irritability. It is independent of the nerves and of sensation, for a portion of muscle removed from an animal body manifests the same contraction when irritated, whether mechanically, galvanically, or chemically. In the living animal the most common stimulus of the muscular contraction is the operation of the nerves, excited by the will, and is commonly the consequence of an act of sensation; but this is by no means the only stimulus by which the irritable property of the muscle is or can be called into play. In plants, universally, there are also irritable parts, or parts which react when stimulated by producing motion of a part or the whole of the body. It is this property which occasions the motion of the cambium or sap; it is by the same endowment that growing plants incline to the light, and extend their roots to the most congenial soil; or entwine their tendrils around the bodies which serve as their support; or move the stamens in regular succession towards the female part or pistil (saxifrage), or incline the pistil successively to each stamen (lily). By a modification of the same irritable property some plants close their leaflets or flowers at sunset; while others, like the nocturnal animals, go to sleep, as it were, at the approach of day. By a higher degree of this irritability the leaflets of the fly-trap (*Dionæa*) approximate each other, and inclose the irritating insect which has alighted upon them; and the Mimosa pudica withdraws its leaves from the offending touch; — while the Desmodium exhibits during the day a constant alternate movement of the lesser folioles, analogous to the quicker vibration of the cilia which beset the respiratory organs of many molluscous animals, and which is equally independent of the nerves and of the will. The conditions of all these vegetable motions, which essentially distinguish them from the voluntary movements of animals, are, that they never proceed from an internal impulse, but are invariably the consequences of external stimulus, and take place, as it were, mechanically, and in the self-same manner; while in animals the motions arise out of an internal determination from parts not moving to the moving powers. There is also an essential difference in the nature of the motion itself, even when we compare the simplest animal with the plant. If we touch the feeler of a polype, it recedes from the irritant by a true contraction of the part within itself; but in the case of the sensitive plant, there is nothing like this contraction of the part touched, but only an articular plication of a contiguous part, without the dimensions of the irritated leaf being altered. Experiment has also shown that the intumescent parts of the mimosa, in which the irritable property is concentrated, move the leaf by an extension of cells, and not a contraction of fibres.

It is true that many of the lower aquatic animals are rooted to the bottom; and these are often aggregated, and grow in a branched or plant-like form, as the serpularia and other corallines; but, although voluntary motion of the whole is impossible, yet it is sufficiently conspicuous in the different parts, and the vital endowments of the individual polypus manifest a multiplied animal enjoyment, not the condition of a vegetable. The simplest monad of infusions exhibits the voluntary characteristics of the animal, by varying its movements to avoid obstacles or seize its food, while the locomotive embryo of the Conferva dilatata proceeds blindly onwards in an unvarying course, till its irritability is exhausted, and excites no idea of animality in the mind of an observer who has had any experience in the observation of animalcules. Ehrenberg has asserted that he can distin-

guish a moving embryo of the Algæ from a polygastric monad as easily as a tree from a bird.

The nerves are the organs on which spontaneous motion and sensation depend, and they chiefly distinguish the animal from the vegetable. Hence the nervous system has been termed the essence of an animal. All the other systems of organs appear in their plan of arrangement to be subject to the modification of the nervous system; and it is upon this system, therefore, that, in the classification of animals, their primary division is founded. Recent and more accurate researches have proved the existence of nerves in many of the lower organised animals, where their presence had been denied; and, as in every species in which the nerves have been detected, sensation has been found to depend exclusively upon them, we are hence led to assume that all animals in which sensation is observable must have it depending on nervous matter present in some condition or other in their tissue; even where, as in the freshwater polype, this is apparently homogeneous, and where, from the extreme divisibility of the individual without loss of vitality in the detached parts, we may reasonably conclude the nervous molecules to be dispersed throughout the corporeal mass.

The attributes of sensation and voluntary motion modify, as might be expected, all the other functions which animals possess in common with plants. For example, as regards nutrition: vegetables which are fixed to the soil absorb immediately by their root the nutritive parts of the surrounding fluid. These roots are indefinitely subdivided; they penetrate the smallest interspaces, and seek, as it were, at a distance, the nourishment of the plant to which they belong. Their action is tranquil, but unintermitting; being only interrupted when dryness has deprived them of the juices which are necessary for them.

Animals, on the contrary, which are rarely stationary, but which have the power of moving, not only parts of the body, but the entire body, from place to place, require the means of transporting the provision necessary for their subsistence; accordingly, they have received an internal cavity, appropriated for the reception of the nutriment, and upon the parietes of which open the pores of the absorbent vessels, which have been justly compared to internal roots.

An internal cavity is requisite for animals on another ground; — their food must first be digested. Plants are supported by water containing carbonic acid, or the already dissolved organised material of the soil. But nutrition in animals does not immediately commence by the absorption of such fluids as the soil or the atmosphere furnishes, but their food consists of substances already in organic combination, which must be prepared and submitted to instruments for dividing and comminuting it, and to the action of solvent fluids. Thus digestion, or the preparatory assimilation of the food, is entirely peculiar to animals. They alone are endowed with organs of sensation, which guide them in the choice of aliment. They alone possess labial and other prehensile organs for seizing the food; teeth and jaws for comminuting and destroying its vitality if living; muscular actions, by which it is swallowed, and a reservoir for its reception endowed with chemical and vital powers for dissolving and assimilating such parts as are proper for nourishment, and which are selected and taken into the system through the purely vital sensibilities of the absorbent internal surface, while such parts as are unfit for nourishment are expelled.

A still more important difference, in connection with the digestive functions, arises out of the limitation of the powers of assimilation in the animal kingdom. Animals can convert into their own substance only matter which has already been organised; while plants have the power of assimilating the inorganic binary compounds, carbonic acid and water. This property of plants is more important than perhaps at first sight might be suspected; for in the vital operations of animals a great quantity of organised matter is constantly decomposed, and is rendered, at all events, useless as nutriment for other animals; while, by means of combustion and other decomposing processes, an incalculable quantity of vegetable matter is continually resolved into binary compounds, or the ultimate elements of matter: hence, if the power of producing new ternary organised compounds out of carbonic acid and water had not been given to plants, both these and animals must, in process of time, inevitably have been annihilated, and successive creations of animals and vegetables would have been indispensable to maintain the present system of things. It is a beautiful instance of the harmony which pervades the relations of nature, that animals contribute as essentially to the support of vegetables, by a process of excretion, as these to the maintenance of animal life, by their powers of assimilation. The product of the respiratory interchange which takes place between the circulating fluids and the atmosphere in animals, is carbonic acid; which is the essential aliment of plants; and which, when in health, and exposed to the influence of the sun's rays, plants absorb from the atmosphere by their respiratory organs, the leaves, and exhale the superfluous oxygen which is extricated in their assimilative processes. Thus the constitution of the atmosphere is maintained by the different products which are evolved in the respiratory processes of plants and animals.

The circulation of the nutrient juices is much more independent of the external influences of light and heat in animals than in plants; and in most classes of the animal kingdom, the motion of the blood is principally determined by the contractions of an express muscular organ called the heart.

From a general review, therefore, of the nature and properties of living animals, their distinguishing characteristics may be summed up as follows: —

Animals are the only beings in nature which manifest sensation and spontaneous movements. They digest organised substances alone, and are always provided with a mouth, and an internal digestive cavity or canal.

Their nutrient fluids are received by an absorbent internal surface; while in plants they are taken up by an absorbent external surface.

Animals at all times, in respiration, exhale carbonic acid and absorb oxygen.

ANIMAL'CULES. *See* Infusores.

ANIMAL SUBSTANCES. The principal products of the animal kingdom are chemically characterised by the presence of nitrogen as one of their ultimate elements, which is generally in combination with carbon, hydrogen, and oxygen. When, therefore, they are subjected to destructive distillation, ammonia is a common product; it is also often evolved when they are triturated with caustic potash, or quicklime.

ANIMA'TION. (Lat. animare, *to enliven.*) In Painting, the expression given to a figure when indicating activity in its members. Thus a figure truly and vigorously executed, is said to be animated.

A'NIME. A resin which exudes from the Hymenæa Courbaril. It is brought from South America. It was formerly used in medicine, but is inert.

A'NIONS. (Gr. ἀνα, *upwards*, and ἰων, *going.*) Substances which in electro-chemical decompositions are evolved from their combinations at the surface by which the electricity enters the electrolyte. (*See* Electrode.)

A'NISE. (Arab. anisun. Gr. ἀνισον.) The aromatic fruit of an eastern annual umbelliferous plant called Pimpinella anisum. It is principally employed in the manufacture of liqueurs, and against flatulence. Star-anise is a very different thing, the produce of Illicium anisatum, a tree belonging to Winteraceæ.

ANISE'TTE. A French liqueur, made by distilling anise, fennel, and coriander seed with brandy, and sweetening the produce.

ANISO'BRYOUS. (Gr. ἀνισος, *unequal*, and βρυω, *I grow.*) A name given by some writers to monocotyledonous plants; having only one colytedon they grow at first with more force on one side of their axis than the other.

ANISODAC'TYLES, ANISODAC'TYLÆ. (Gr. ἀνισος, *unequal*, and δακτυλος, *a digit.*) The name given by Temminck to an order of birds, including those Insessorial species the toes of which are of unequal length, as in the nuthatch.

ANISODY'NAMOUS. (Gr. ἀνισος, *unequal*, and δυναμις, *power.*) A name given to monocotyledonous plants, for the same reason as anisobrious; which see.

ANISOSTE'MONOUS. (Gr. ἀνισος, *unequal*, and στημων, *a stamen.*) When the number of stamens in a flower neither corresponds with the calyx nor corolla in number or power; as, for instance, when a flower having five sepals has three or seven stamens; in such a case the stamens are neither equal to the number of sepals nor any power of their number.

ANISO'STOMOUS. (Gr. ἀνισος, *unequal*, and στομα, *a mouth.*) When the divisions of a calyx or a corolla are unequal. Seldom used; the term unequal or irregular is usually employed instead.

ANISOTO'MIDÆ. (Gr. ἀνισος, *unequal*, and τεμνω, *I cut.*) A family of Coleopterous insects, having moniliform, or beaded, antennæ, subelongate, slender at the base, gradually increasing towards the apex, with a terminal club-shaped multiarticulate joint; palpi various, generally filiform; head small and ovate; body convex, never linear. This family includes eight genera: *Tritoma*, of which we have one indigenous species, *Tr. bipustulatum*; *Phalacrus*, of which Stephens describes twenty-eight British species, remarkable for their brilliant colours, and faculty of rolling up the body into a ball; *Ephistemus*, of which only three species are known, which have been detected in the neighbourhood of London; *Leiodes*, abundant in species, of which twenty-six are British; *Agathidium*, of which we have twelve species, inhabiting putrid wood and fungi, also found near London; *Clambus*, of which various species, all extremely minute are known; *Clypeaster*, a term already appropriated to a genus of *Echinidæ*; lastly, *Sericoderus*; distinguishable from the rest of the family by its truncate elytra.

A'NKER. A measure of wine or spirits equal to 10 of the old gallons, or $8\frac{1}{3}$ imperial gallons, = 2310·6 cubic inches.

A'NNALS. A chronological history: derived from the Roman "Annales Pontificum," or "Annales Maximi," which were annual records of passing events connected with religious observances, kept by the Pontifex Maximus.

Annals are a species of historical writing; but they seem, notwithstanding, to differ materially from history, as the latter is now understood. Annals should comprise a succinct account of the events having reference to some peculiar subject, as they occur in successive years. Inquiries as to the remote causes and consequences of events seem to be misplaced in them; though they are the essence of history. Cicero, when speaking of annalists, says, "*Unam dicendi laudem putant esse brevitatem, non exornatores rerum, sed tantum narratores.*" Annals are, in fact, rather materials for history, than history. In the one, events only are narrated, in the other they are narrated and reasoned upon. The annalist may, no doubt, reason upon facts as well as the historian; but such reasonings are not so well or happily placed in a book divided into years, as in one that depicts the continuous stream of events, without breaking it into limited compartments. Hailes's "Annals of Scotland" is, perhaps, the best work of its class in English literature.

ANNA'TES, or FIRST FRUITS. A fine paid to the king, as head of the church, by one promoted to an ecclesiastical benefice, and supposed to amount to one year's value of that benefice. This, however, is evaded by assuming as the basis of the valuation that made in 1535, and contained in what is termed the "Liber Regis." In England, first fruits go to the augmentation of Queen Anne's bounty.

ANNEA'LING. (Anhelan, Sax.) There are many substances which, when rapidly cooled, after having been heated, become exceedingly brittle; an inconvenience often prevented by very slow cooling: this is especially the case with glass, which is therefore suffered to cool very gradually in an oven constructed for the purpose, and the process is called annealing. Many of the metals which have become harsh and hard in the process of manufacture, are softened in the same way; thus the blank pieces for coinage, several metallic wires, &c. are annealed.

ANNE (ST.), ORDER OF. An order of knighthood, originally established in Holstein, and carried with the princes of that country into Russia. It was made a Russian order in 1796; and is now widely diffused.

ANNO'TTA. Is the pulp of the seeds of the Bixa Orellana, an exogenous tree common in Cayenne and other parts of America: it is made into a pulp, which, after having fermented, is rolled into pieces of two or three pounds' weight: it is imported under the names annotto, Roucou, or Orleans, and is used occasionally as an orange dye and for colouring cheese. It imparts little colour to water, but dissolves in alcohol and in alkaline solutions; its colour is not materially altered by acids or alkalis.

ANNO'NA. In Roman writers, means, in a general sense, the year's increase, or the fruits of the year; and it also means the contribution or tax payable in corn, imposed on some of the more fertile provinces of the empire, as Sicily, Egypt, &c., for the use of the army and of the capital. The poorer class of citizens were entitled to a share of this tribute; and their habitual dependence on it was not only a fruitful source of idleness, but of all sorts of disorder. To grant an increased allowance of corn was one of the surest methods by which to attain popular favour.

> ——— *Summa favoris*
> *Annona momenta trahit.* Namque asserit urbes
> Sola fames, emiturque metus, cum segne potentes
> Vulgus alunt. Nescit plebes jejuna timere.

The office of Præfectus Annonæ was of great importance at Rome, and was generally, indeed, exercised by the emperors. (See, for further particulars, Contarenus, *De Re Frumentaria*, passim.)

A'NNUAL. (Lat. annus, *a year.*) A plant which arrives at perfection, passing from a seed into a perfect plant, yielding its fruit, and perishing, within the space of a year. The term also applies to all cases where duration is for one growing season only. Many plants have perennial roots and annual stems; that is, stems perishing and being renewed annually: such plants are usually denominated Herbaceous.

ANNUAI'RE. A name given by the French to publications on continuous or similar subjects, which appear in yearly parts or numbers. Of the existing *Annuaires*, that published by the *Bureau des Longitudes* is the most celebrated. There are also an *Annuaire Historique*, corresponding to our *Annual Register*, an *Annuaire de l'Etat Militaire*, an *Annuaire du Clergé de France*, &c.

ANNU'ITY. A rent or sum receivable yearly for a term of years.

An annuity may be receivable during a definite number of years, or during a period of uncertain length; for example, during the life of one or more individuals. In the former case it is called an *Annuity Certain*; in the latter, a *Contingent Annuity*.

An annuity which is not to be entered upon immediately, but after a certain number of years, is called a *Deferred Annuity*; if it is not to be entered upon till after the death of some person or persons now living, it is called a *Reversionary Annuity*. When limited by the duration of a given life or lives, it is called a *Life Annuity*; and when it is to continue only for a term of years, provided an individual or individuals now living shall survive that term, it is called a *Temporary Life Annuity*.

The practice of raising or investing money on annuities is attended with many advantages in the ordinary affairs of the world. A merchant or trader thus finds the means of clearing off his engagements gradually by the profits of his trade, and without losing possession of the capital necessary for carrying on his speculations; and one who possesses unemployed capital is thus enabled to convert it into an equivalent annual income for life, and thereby derive the utmost benefit from it while he lives, without risk of destitution from its failure. The accurate determination of the value of annuities in present money, is therefore a subject of very considerable importance. We propose to explain the principles on which the calculation is made, and to apply them to a few of the cases of most frequent occurrence.

Annuities Certain.—The values of annuities of this kind depend only on the rate of interest of money, and the number of years during which they are payable; and are easily calculated. Suppose it were required to determine the value, in present money, of an annuity of £100 per annum, to continue five years, or till five payments have been made, the interest of money being 5 per cent., we should reason as follows.—The first payment of £100 becomes due at the end of a year from the present time; but since £100 in hand is equal to £105 receivable at the end of a year, the present value of the first annual payment is £100 reduced in the proportion of 100 : 105, or of 1 to 1·05; that is, it is equal to £$\frac{100}{1·05}$. In like manner, the present value of £100, to be received at the end of two years, is less than if it were receivable at the end of one year, in the proportion of $\frac{1}{1·05}$; consequently, the present value of £100, to be received at the end of two years, is £$\frac{100}{(1·05)^2}$. Pursuing the same reasoning, the present value of £100, to be received at the end of three years, is £$\frac{100}{(1·05)^3}$; at the end of four years, it is £$\frac{100}{(1·05)^4}$; and so on till the end of the term. But it is evident that the present value of the whole annuity is the sum of the values of all the annual payments; hence the required value of the proposed annuity is—

$$\frac{100}{1·05} + \frac{100}{(1·05)^2} + \frac{100}{(1·05)^3} + \frac{100}{(1·05)^4} + \frac{100}{(1·05)^5}$$

This reasoning may be easily generalised. Let a denote the annual payment, r the rate of interest, n the number of years during which it continues, and S the present value of all the payments, we shall then have—

$$S = \frac{a}{1+r} + \frac{a}{(1+r)^2} + \frac{a}{(1+r)^3} + \ldots \frac{a}{(1+r)^n}$$

For the sake of abridging, put $v = \frac{1}{1+r}$, and the formula will become—

$$S = a\,(v + v^2 + v^3 \ldots\ldots\ldots + v^n)$$
$$\text{or } S = av\,(1 + v + v^2 + v^3 \ldots + v^{n-1})$$

The sum of the series within the parenthesis is $\frac{1}{1-v^n}(1-v^n)$; therefore, $S = \frac{av}{1-v}(1-v^n)$; or, writing $\frac{1}{r}$ for $\frac{v}{1-v}$ $S = \frac{a}{r}(1-v^n)$.

From this it is easy to see the method of proceeding in all other cases of annuities certain. For instance, let it be required to find the present value of an annuity deferred for three years, that is, not to be entered upon till after the end of three years; and to continue ten years from that time. It is evident that we have only to find the value of an annuity of the same amount for thirteen years, and also for three years, and to subtract the latter value from the former. The difference is the value of the deferred annuity. Again, suppose that the annuity, instead of being payable yearly, is to be paid half yearly, or quarterly. It is obvious that an annuity of £100 per annum for ten years, to be paid in half yearly payments, the interest of money being 5 per cent., is the same thing as an annuity of £50 per annum for twenty years, payable yearly, interest being $2\frac{1}{2}$ per cent.; or an annuity of £25 per annum, payable yearly for forty years, interest being $1\frac{1}{4}$ per cent. The principle of the calculation is the same in all the cases.

Life Annuities. — When the annuity is to cease with the life of an individual, or any number of individuals, the calculation of its value is a little more complicated, as it becomes necessary not only to find the present value of the payment to be made at the end of any given year, but also to take into account the probability of its being received, that is to say, the probability that the individual or individuals, on the duration of whose lives it depends, will be alive at that period. Let the annuity depend on the continuance of a single life, and let us denote the probability that the life will be in existence at the end of

	1,	2,	3,	4,	5, &c. years,
by	p_1,	p_2,	p_3,	p_4,	p_5, &c.;

and, as before, let $v = \frac{1}{1+r}$. The present value of £1, to be received certainly at the end of a year, is v; but the probability of receiving it is p_1; therefore, the value of £1 at the end of the year, subject to the chance of the given life being then in existence, is $p_1 v$. In like manner, the value of £1, to be received certainly at the end of two years, is v^2; and the chance of its being received is p_2; therefore, the value subject to the contingency is $p_2 v^2$, and so on. Let A denote the value of £1 to be received yearly during the whole continuance of the given life, and we have evidently

$$A = p_1 v + p_2 v^2 + p_3 v^3 + p_4 v^4 + \&c.$$

continued till p becomes nothing, or till the extremity of human life.

It is now necessary to consider the nature of the quantities represented by p_1, p_2, p_3, &c., and to show in what manner they are to be computed. By the doctrine of chances, the probability of the occurrence of any event is measured by the quotient that arises from dividing the number of chances favourable to its occurrence by the whole number of ways in which it can happen. Consequently, if n denote the number of individuals living at a given age, n_1, the number of the same individuals alive at the end of one year, n_2 the number living at the end of two years, n_3 the number living at the end of three years, and so on, we shall have $p_1 = \frac{n1}{n}, p_2 = \frac{n2}{n}, p_3 = \frac{n_3}{n}, p_4 = \frac{n4}{n}$, and so on. The numbers n, n_1, n_2, &c., are taken from a table of mortality, or a table constructed to show the ratio of the number of individuals who enter upon every given year of life to the number who survive that year, or who die in the course of it.

There is no other method of finding the value of the series represented by A than that of calculating the value of its different terms separately, and adding the whole into one sum. Nevertheless, as the object in general is not to determine merely the value of an annuity on a life at a particular age, but to construct a table showing its value for all the different ages of life, there is a method of deducing the value at one age from the value at another age, which greatly abridges the labour of calculation. Thus, suppose the age of the individual on whose life the annuity depends to be 40, and the probabilities of a life of 40 continuing 1, 2, 3, &c. years to be p_1, p_2, p_3, &c., we have, by what is already shown,

$$A = p_1 v + p_2 v^2 + p_3 v^3 + \ldots + p_x v^x.$$

Now, let A_1 be the annuity on a life of 41, that is, one year older than the former; and let the probabilities of a life of 41 living over 1, 2, 3, &c. years, be q_1, q_2, q_3, q_4, &c., we shall have

$$A_1 = q_1 v + q_2 v^2 + q_3 v^4 \ldots + q_4 v^{x-1}.$$

But the quantities q_1, q_2, q_3, &c. are not independent of p_1, p_2, p_3, &c.; the one set are evidently functions of the other. In fact, the probability that a life of 40 will live over 2 years, is equal to the probability that a life of 40 will live over 1 year, multiplied into the probability that a life of 41 will live over 1 year. This is evident from the manner in which the probabilities are obtained; for, n, n_1, n_2, being the numbers respectively alive at the ages of 40, 41, and 42, the probability that a life of 40 will live over 1 year, is $\frac{n_1}{n}$, and that it will continue 2 years, $\frac{n_2}{n}$ or $\frac{n_2}{n_1} \times \frac{n_1}{n}$. In like manner, the probability of a life of 40 living over 3 years, is equal to the probability of a life of 40 living over 1 year multiplied into the probability that a life of 41 will live over 2 years; and so on. Hence, $p_2 = p_1 q_1$, or $q_1 = \frac{p^2}{p_1}, q_2 = \frac{p_3}{p_1}, q^3 = \frac{p_4}{p_1}$, and so on. We have, therefore,

$$A_1 = \frac{p_1}{1} (p_2 v + p_3 v^2 + p_4 v^3 \ldots + p_x v^{x-1});$$

and, multiplying both sides by $p_1 v$,

$$p_1 v A_1 = p_2 v^2 + p_3 v^3 + p_4 v^4 \ldots + p_x v^x.$$

On subtracting this equation from

$$A = p_1 v + p_2 v^2 + p_3 v^3 + p_4 v^4 \ldots + p_x v^x$$

we get $A - p_1 v A_1 = p_1 v$, whence $A = p_1 v (1 + A_1)$. This formula, which was found by the celebrated Euler, gives the following rule for determining the value of an annuity on a life at any age from the value of the same annuity on a life one year older, and renders the computation of the whole table not much more laborious than the direct calculation of the annuity on the youngest life. "To the value of an annuity on a life one year older, add unit; multiply the sum by the probability that the given life will live over one year, and also by the present value of £1 to be received at the end of a year. The product is the value of the annuity on the given life."

The values of deferred and temporary annuities on single lives, are easily found from the table of the values for the whole of life. For example, let it be required to determine the present value of an annuity on the life of an individual now aged 40, but deferred 10 years, that is to say, not to commence till the expiration of 10 years. After the 10 years, if the individual be then alive, the value of the annuity on the remainder of his life is the annuity on a life of 50: let this be called B. The present value of £1 payable at the end of 10 years is v^{10}; and the probability of receiving it in the event of an individual now aged 40 being then alive, is p_{10}; therefore, the present value of B subject to the contingency, is $p_{10} v^{10}$ B. In general, the value of an annuity deferred n years, is $p_n v^n A_n$, where A_n represents the annuity on a life n years older than that corresponding to A.

A temporary annuity on a single life for n years, is found by adding together the first n terms of the series

$$p_1 v + p_2 v^2 + p_3 v^3, \&c.$$

But it is frequently more easy to find it by means of the deferred annuity on the same life for the same term of years; for it is obvious that the temporary annuity and deferred annuity are, together, equal to the whole annuity. Thus, let A be an annuity for the whole of life, A_{tn} a temporary annuity of the same amount for n years on the same life, and A_{dn} the same annuity deferred n years, we shall have $A_{tn} = A - A_{dn}$.

Annuities on Joint Lives. — The method of calculating annuities to be paid so long as two or more individuals shall continue to live together, is equally simple. Let the probabilities that A and B will live over

	1,	2,	3,	4, &c. years
be	p_1,	p_2,	p_3,	p_4, &c.
	q_1,	q_2,	q_3,	q_4, &c.

respectively, then the probability that both will live over

	1,	2,	3,	4, &c. years
will be	$p_1 q_1$,	$p_2 q_2$,	$p_3 q_3$,	$p_4 q_4$, &c.,

and the value of an annuity on their joint lives, which we may denote by Æ, becomes

$$Æ = p_1 q_1 v + p_2 q_2 v^2 + p_3 q_3 v^4 + p_4 q_4 v^4 + \&c.,$$

continued till p or q becomes nothing, or to the last age in the table. When more lives than two are involved, the method of proceeding is obvious.

Another question of this kind frequently occurs, namely, to determine the value of an annuity on the survivor of two or more lives. Let us suppose two lives only are concerned; and let A be the value of the annuity on the first life, B that on the second, and Æ that on the joint lives (*i. e.* to be paid till one of the lives shall drop). Let $p_x =$ the probability the first will live over x years, and $q_x =$ the probability the second will live over x years. We shall then have

$1 - p_x =$ probability 1st will die before the end of x years,
$1 - q_x =$ prob. 2d will die before the end of x years,
$(1 - p_x)(1 - q_x) =$ prob. both will die before end of x years;

and hence the probability that both will not die before the end of x years, is $1 - (1 - p_x)(1 - q_x)$, which is equal to $p_x + q_x - p_x q_x$. This expression, therefore, is the measure of the probability that a payment will be received at the end of the xth year; and supposing the annuity to be £1, the present value of that payment certain is v_x. Multiplying this into the above probability, we get the value in present money of the payment to be made at the xth year, if one or both of the lives survive, viz.

$$p_x v^x + q_x v^x - p_x q_x v^x.$$

Now, if we substitute successively the numbers 1, 2, 3, 4, &c. for x in this expression, we shall have the value of the 1st, 2d, 3d, 4th, &c. payment, and the sum will be the value of the annuity to continue during the life of the survivor. But it has been shown that

$$p_1 v^1 + p_2 v^2 + p_3 v^3 + p_4 v^4 + \&c. = A,$$
$$q_1 v^1 + q_2 v^2 + q_3 v^3 + q_4 v^4 + \&c. = B,$$
$$p_1 q_1 v^1 + p_2 q_2 v^2 + p_3 q_3 v^3 + p_4 q_4 v^4 + \&c. = Æ;$$

therefore, the value of the annuity is A + B — Æ; that is to say, *the value of an annuity on the survivor of two lives is equal to the sum of the annuities on each of the single lives diminished by the annuity on the joint lives.* (For applications of the doctrine of annuities, see the terms Assurance, Survivorship.)

Annuity Tables. — In consequence of the numerous and important application of the doctrine of life annuities to commercial purposes, great pains and labour have been bestowed in the formation of tables of their values at all

the different ages of human life. These tables differ very considerably, not from any difference in the methods of constructing them, but from the difficulty of estimating with numerical precision the probable duration of human life. The first table of the kind which we possess was given by Dr. Halley, in a paper inserted in the "Philosophical Transactions" for 1693, and founded on observations of mortality made at Breslaw. De Moivre, in a tract entitled "Annuities on Lives," published in 1724, gave a very elegant formula for determining the value of a life annuity at any age, founded on the hypothesis that the annual decrements of life are equal; or that out of a given number of individuals, equal numbers die every year, till the whole become extinct. In 1742, Thomas Simpson published tables of annuities on single and joint lives, calculated from observations of mortality made in London. These were extended in a supplementary work published in 1752. Deparcieux, in 1746, published his excellent "Essai sur les Probabilités de la Durée de la Vie Humaine," with tables of annuities on single lives, calculated from the probabilities deduced from the registers kept in different religious houses, and the lists of the nominees in the French Tontines. These tables were decidedly the best that had then appeared, and even now, when much more extensive observations have been obtained, are of great value. But the tables which acquired the most extensive reputation were the celebrated Northampton Tables, calculated by Dr. Price from registers kept in the city of Northampton. These, till a late period at least, have formed the guide of the transactions of all the assurance offices. They give the probabilities of life, and consequently the value of the annuities, considerably lower than all other good observations have subsequently proved them to be; but, in proportion as the annuities are too low, the premiums for assurance deduced from them are too high; and hence they were extremely safe for the offices, though proportionally unjust for the assured. In consequence of the competition resulting from the recent great increase in the number of assurance offices, they now transact their business on more equitable terms. An extensive set of annuity tables was given by Mr. Milne in his "Treatise on the Valuation of Annuities and Assurances on Lives and Survivorships," published in 1815. One of these tables, founded on observations made at Carlisle, has acquired considerable reputation, and perhaps gives a nearer representation of the value of life at present in England generally than any other which has yet been published. The annuities granted by government are now valued according to a table calculated by Mr. Finlaison from the mortality experienced among the different classes of annuitants. This table possesses a great advantage over most others, inasmuch as it is founded on observations of the actual numbers who entered upon and passed through the several years of age among a class of individuals none of which could be lost sight of, so that no uncertainty remains about the accuracy of the data. The values of the annuities are in general considerably higher than those given by the Northampton Table, at the same rate per cent., and approach to those of the Carlisle Table. The observations also indicate a considerable difference between the values of male and female life at the same ages; a fact which appears to be borne out by all the accurate registers of mortality which have been kept in this and other European countries. (*See* MORTALITY.)

The following table, extracted from Mr. Finlaison's Report to the Lords Commissioners of the Treasury (March, 1829), shows the value of a life annuity of £1 at all the different ages of male and female life to 90, according to the mortality among the government annuitants, the rate of interest being 4 per cent.

VALUE of a LIFE ANNUITY of £1, Interest being 4 per Cent.

Age.	Male.	Female.	Age.	Male.	Female.

ANNUITY. In Law. A sum of money paid yearly. and charged on the personal estate, or on the person, of the individual from whom it is due: thus differing from a rent-charge, which is charged on real estate. Annuities are commonly employed as a system of borrowing and lending; the borrower of the money being the grantor of the annuity, and the lender the grantee. An annuity is either for a term of years, for a life or lives, or in perpetuity; and the latter, although charged on personal property, may by the terms of the grant descend as real estate. A perpetual annuity is redeemable by the grantor, subject, however, to conditions in the grant, by which he may preclude himself from redeeming for a certain period of years. An annuity for life or years is only redeemable by consent of the parties, unless it has been rendered redeemable on specific conditions in the original grant. Annuities for life, on account of the risk to which the grantee is exposed, are not within the usury laws: they are, therefore, commonly resorted to as a mode of raising money by loan at high interest. By the stat. 53 G. 3. c. 141., a memorial of every instrument by which annuities for life are granted, must be enrolled in the Court of Chancery, containing the date, names of parties and witnesses, and conditions of contract, and the grantor may have the instrument cancelled, if the consideration money is not *bonâ fide* paid him. This act is intended to relate only to annuities, granted in return for loans. Annuities created by will are general legacies, and subject to abatement, in proportion with other legacies, on a deficiency of the funds of the testator. If a person on whose life an annuity is charged dies between two days of payment, the grantee has no claim pro rata, for the proportionate amount of the yearly or quarterly sum incurred since his death. This act is further explained by 3 G. 4. c. 92., 7 G. 4. c. 75.

AN'NULAR ECLIPSE. An eclipse of the sun, in which the moon conceals the whole of the sun's disk, excepting a bright ring all round the border. (*See* ECLIPSE.)

AN'NULATE. Formed or divided into distinct rings, or marked with differently coloured annulations.

AN'NULET, (Lat. annulus, *a little ring.*) In Architecture. A small square moulding which crowns or accompanies a larger. Also that fillet which separates the flutings of a column, though improperly used in that sense. It is sometimes called a list or listella; which see.

ANNULO'SA. (Lat. annulus, *a ring.*) A term used to designate, sometimes a part, sometimes the whole, of the Articulate division of Invertebrate animals.

A'NNULUS. (Lat. annulus, *a ring.*) This word is used in Botany in several different senses. In the mushroom and some other fungi it is applied to a collar which surrounds the stipes just below the hymenium; in mosses it signifies a rim external with respect to the peristome; in ferns it is an elastic rib which girds the theca nearly all round, and which by its contraction tears the theca open and disperses the spores.

ANNUN'CIA'TION, ORDER OF THE. Founded in Savoy by Amadeus VI., in 1335, as the order of the Collar: received its present name from Charles III. The reigning king of Sardinia is grand master of the order.

ANNUNCIATION, *Feast of the.* A festival of the Christian church, in commemoration of the announcement of the conception of our Saviour to the Blessed Virgin, by the angel Gabriel. (St. Luke i. 26. 38.) It is celebrated on the 25th of March, commonly called Lady-day.

ANO'BIUM. The name of a Fabrician genus of Coleopterous insects, characterised by antennæ filiform, the last joints larger; thorax nearly round, not margined, receiving the head; palpi clavate; labium entire.

A'NODE. (Gr. ἀνα, *upwards*, and ὁδος, *a way.*) The way by which electricity enters substances through which it passes: opposed to cathode, the road or way by which it goes out.

A'NODON. (Gr. ἀ, priv., ὀδους, *a tooth.*) The name of a genus of Lamellibranchiate Bivalves, including the common freshwater muscle, the shell of which has no

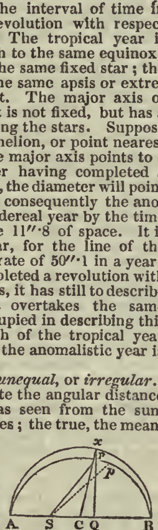
articular processes, or *teeth*, at the hinge. The name has also been applied to a genus of serpents, which have the teeth in the mouth very minute, or rudimental: the *Anodon*, *Typus* (*Coluber scaber* of Linnæus), a South African species of this genus, lives upon the eggs of birds, which, by the structure of the mouth above mentioned, it is enabled to swallow entire. The inferior spinous processes of the cervical vertebræ are prolonged into the gullet, and there receive a coating of enamel; thus serving the office of teeth where the breaking of the egg may take place without the loss of any of its nutritious contents.

A'NODYNE. (Gr. ἀ, *without*, and ὀδύνη, *pain.*) A term applied in Physic to medicines which relieve pain. Anodynes are chiefly of vegetable origin, and generally come under the head of sedatives or narcotics.

ANO'LIS. *Anoli*, *anoalli*, is the vernacular name, in the Antilles, of the lizard to which the generic term *Anolis* is applied. This term is restricted in Zoology to those Iguanoid species of lizard which have minute scales on the under part of the last joints of the toes, while the next joints are extended into soft pads transversely striated, but not organised to act as a sucker, as in the Geckos. All the species of Anolis are natives of the warmer parts of the American continent; all are remarkable for their power of inflating the skin of the throat; they are light and agile in their movements; and in the beauty and brilliancy of their colour exceed all others of the Saurian order.

ANO'MALI'STIC YEAR. The interval of time in which the earth completes a revolution with respect to any point in its elliptic orbit. The tropical year is measured by the return of the earth to the same equinox; the sidereal year by its return to the same fixed star; the anomalistic year by its return to the same apsis or extremity of the greater axis of its orbit. The major axis of the diameter of the earth's orbit is not fixed, but has a progressive motion eastward among the stars. Suppose that when the earth is at its perihelion, or point nearest the sun, the other extremity of the major axis points to a given star; when the earth, after having completed a revolution, returns to its perihelion, the diameter will point $11''\cdot8$ eastward of the same star; consequently the anomalistic year is longer than the sidereal year by the time which the earth takes to describe $11''\cdot8$ of space. It is still longer than the tropical year, for the line of the equinoxes goes backwards at the rate of $50''\cdot1$ in a year; therefore, after the earth has completed a revolution with respect to the line of the equinoxes, it has still to describe $50''\cdot1 + 11''\cdot8 = 61''\cdot9$, before it overtakes the same point of its ellipse. The time occupied in describing this arc is 25 minutes, and the length of the tropical year is 365 d. 5 h. 48 m. 45 s.; therefore the anomalistic year is 365 d. 6 h. 13 m. 45 sec.

ANO'MALY. (Gr. ἀνώμαλος, *unequal*, or *irregular.*) A term used in Astronomy to denote the angular distance of a planet from its perihelion, as seen from the sun. There are three different anomalies; the true, the mean, and the eccentric. Let A*p*B be the orbit of a planet, S the sun, A B the transverse diameter, and C the centre. Through *p* draw P Q perpendicular to A B, meeting the circle circumscribed about the orbit in *x*. On account of its unequal distances from the sun, the angular motion of a planet in its orbit is irregular: conceive, therefore, that while the real planet moves from A to *p*, another planet moving in the same orbit, with an equable motion, and performing a revolution in the same time, has moved from A to P. This being supposed, the angle A S *p* is the true anomaly; A S P is the mean anomaly; and A C *x* the eccentric anomaly. The mean anomaly is proportioned to the time of description; to find the true anomaly, is a problem of considerable difficulty, requiring the aid of the higher mathematics. From the circumstance of its having been first proposed by Kepler, it is usually called Kepler's problem.



ANOMALY. In Grammar, an exception from a general rule.

ANO'MIA. (Gr. ἀ, *without*, νόμος, *a law*; because not easily reduced to the ordinary laws of classification.) The name of a Linnæan genus of the Vermes Testacea, the characters of which, as given in the *Systema Naturæ*, apply to the organisation of the soft parts and shell of the modern Terebratulæ. In the system of Cuvier the term *Anomia* is limited to a genus of Acephalous Mollusca, having two unequal irregular thin valves, of which the flatter one is deeply notched at the cardinal margin. The greatest part of the central muscle traverses this opening to be inserted into a third piece, which is sometimes calcareous, and sometimes simply horny, but which is always attached to foreign bodies. The rest of the muscle serves to join one valve to the other. The animal has a small vestige of a foot, and is remarkable for the length of its labial tentacles.

AN'ONA. (Menona, the Malayan name of *the custard apple.*) A genus of trees found in hot latitudes, with large roundish pulpy fruit, which in some species is used as food. The custard apple, so named from its seeds lying in a whitish sweet cream like pulp, is produced by A. squamosa; the cherimoyer, the most esteemed of all the fruits in Peru, is yielded by another; and other kinds are known.

ANONA'CEÆ. (See ANONA.) An extensive natural order of Exogenous plants, comprehending evergreen trees or shrubs, whose fruit is sometimes eatable, as in Anona, more generally dry and aromatic, as in the genera Unona, Habzelia, &c., whose ripe carpels furnished the Piper æthiopicum of the old drug shops. The great mark of Anonaceæ is their having ternary (trimerous) flowers, and a ruminated albumen.

ANO'NYMOUS. (Gr. ἀνώνυμος, *nameless*, from ὄνομα, *a name.*) In Literature, works published without the name of the author. Those published under a false name are termed *Pseudonymous* (ψεῦδος, *falsehood*). The best catalogue of anonymous works is that of Barbier (*Dictionnaire des Œuvrages Anonymes et Pseudonymes*, 3 vols. Paris, 1822-1824). There is also the great work of Placcius, *Theatrum Anonymorum et Pseudonymorum*, t. fol. Hamburg, 1708.

ANOPLOTHE'RIUM. (Gr. ἄνοπλος, *unarmed*, and θηρίον, *beast.*) The name of a genus of extinct animals of the order Pachydermata, characterised by the shortness and feeble size of the canine teeth, which resemble the incisors, and are consequently unfitted for being used as weapons of offence. As the canines in this genus do not project beyond the level of the incisors and molar teeth, no vacant interspace is required in the dental series of the opposite jaw for the reception of their pointed extremities, and consequently the series of teeth is uninterrupted in both jaws, — a structure observable in no existing animal save man. The Anoplotherium has 6 incisors, 2 canines, and 14 molars in each jaw. The best known (*Anoplotherium commune*, Cuv.) is about the size of a wild boar, but longer in the body, with the head of an oblong form, and a tail of considerable thickness, and as long as the body. Its probable use was to assist the animal in swimming. Another species of Anoplotherium (*A. medium*) is of a size and form more nearly approaching to the light and graceful character of the gazelle; a third species was about the size of a hare. All the species, from the form of the teeth, and the absence of claws or horns, appear to have been singularly deficient in defensive organs.

ANORE'XY. (Gr. ἀ, *without*, and ὄρεξις, *appetite.*) Loss of appetite.

ANO'SMIA. (Gr. ἀ, *without*, and ὀσμή, *smell.*) Loss of the sense of smelling.

ANO'STOMA. (Gr. ἄνω, *upwards*, and στόμα, *mouth.*) A genus of Pulmonate, or air-breathing Gastropods, the adult shell of which presents the following peculiarity, — the last whorl turns upwards towards the spire of the shell.

ANOU'RANS, ANOU'RA. (Gr. ἀ, priv., and οὐρά, *tail.*) A name applied to a tribe of Batrachian reptiles, which lose the tail in arriving at maturity; as the toad and frog.

A'NSERES. (Lat. anser, *a goose.*) In the Linnæan arrangement, the name of the third order of birds, having the bill broad at the top, and covered with a soft skin; the feet webbed. (*See* NATATORES.)

ANT. *See* FORMICA.

A'NTA, Æ. plur. (Lat. ante, *before.*) In Architecture, a pilaster or square projection attached to a wall. When they are detached from the wall, Vitruvius calls them parastatæ. They are not usually diminished even when accompanying columns from whose capitals, in all Greek works, they vary.

ANTA'CIDS. Medicines which neutralise the acid of the stomach.

ANTA'LGIC. (Gr. ἀντί, *against*, and ἄλγος, *pain.*) That which relieves pain.

ANTANACLA'SIS. (A compound word from the Greek prepositions ἀντί and ἀνά, and the verb κλάω, *I break.*) In Rhetoric and Composition, a figure in which a word is repeated, but in a different sense or different inflection from the first; which gives a kind of antithetical force to the expression.

"Labitur, et labetur in omne volubilis ævum."

The return to the former series of thought and diction after the interruption of a parenthesis. is also termed Antanaclasis.

A'NTAPHRODI'SIACS. (Gr. ἀντί, *against*, and Ἀφροδίτη, *Venus.*) Medicines which quell amorous desires.

ANTA'RCTIC. (Gr. ἀντί, *against*, and ἄρκτος, *a bear.*) Opposite to Arctic. Antarctic circle, one of the small circles of the sphere, parallel to the equator, and distant 23° 27½′ from the South pole. Antarctic pole, the South pole, or southern extremity of the axis of the earth. (*See* ARCTIC.)

ANTECE'DENT. In Analysis, the name given to the first of the two terms composing a ratio. Thus in the ratio $a:b$, a is the antecedent, and b is denominated the consequent.

ANTECEDENT. In Logic, the first member of an hypothetical proposition; followed by the consequent; as in the following instance: —

If we say we have no sin (*antecedent*),
We deceive ourselves (*consequent*).

ANTEDILU'VIAN. (Lat. ante, *before*, and deluvium, *deluge*.) Something that existed before the deluge.

ANTELOPE. *See* ANTILOPE.

ANTE'NNA. (Lat. *a yard arm.*) A moveable, tubular, and jointed sensiferous organ situated on the head; and peculiar to the Condylope Articulata. Certain Annelides carry soft tentacles or filaments upon the head, which have been termed antennæ; but improperly, according to the above definition, which would restrict the phrase to the jointed antennæ of insects and crustaceans. In the latter class the antennæ are commonly four in number, consisting each of a 'scape,' a 'pedicel,' of two joints, and a 'clavolet'; the latter is setaceous, and divided into a vast number of minute joints. It is simple in the external antennæ, but in the internal pair is always composed of two and sometimes of three setaceous filaments. The internal pair of antennæ are situated before or between the eyes, the external behind, at the outer sides of the eyes. In insects the antennæ are always two in number, and situated in the space between or before the eyes; they consequently correspond to the internal antennæ of crustaceans. The cavity or socket in which the base of the antennæ is planted is called the 'torulus,' or bed. The first, and in many cases the most conspicuous, joint of the antennæ is termed the scape. The base of the scape, by which it is articulated with the torulus, is the bulb. It often looks like a distinct joint, and is the point upon which the antenna turns. The pedicellus, or second joint of the antenna, in some insects, also acts the part of a pivot in the bed of the scape, in order to give a separate motion to the clavola, or clavolet. This, which includes the remaining joints of the antenna taken together, is occasionally terminated by a capitulum or knob; a term applied to the last joints of the clavolet when suddenly larger than the rest. (For the varieties of antennæ with respect to situation, approximation, proportion, direction, figure, termination, and appendages, the reader is referred to the 4th vol. of Kirby and Spence's *Introduction to Entomology*.)

ANTE'NNULÆ. (Dim. of antenna.) A term sometimes applied to the articulated filaments attached to the jaws or lower lip of Mandibulate insects, and which seem to be endowed with a sensiferous faculty specially adapted to distinguish kinds of food, and applied by the animal to that use: these organs are more commonly called palps, palpi, or feelers.

A'NTEPAGME'NTA. (Lat.) In Architecture, the mouldings or architraves round doors; also the jambs of a door.

ANTEPE'CTUS. In Entomology, signifies the under side or breastplate of the manitrunk, and the bed of the first pair of extremities or arms.

A'NTEPENU'LT, or ANTEPENULTIMA. In Grammar and Prosody, the last syllable of a word but two.

ANTE'RIOR. (Lat. ante, *before*.) This is said either when of two lobes of a stigma, one, the anterior, is directed towards the front of a flower, and the other, the posterior, towards the back, or in any other similar case. It is also applied to certain stipules, which stand between the petiole and stem of a plant, adhering to the former, as in some Cinchonaceous plants.

ANTESIGNA'NI. A class of soldiers in the Roman army, who were drawn up in front of the standards (*ante signa*), whence they derived their name. As their post was one that demanded great courage and firmness, they were picked troops.

ANTHE'LA. (Gr. ἀνθήλιον, *a little flower*.) A name given by Meyer to the inflorescence of rushes.

ANTHE'LIX. (Gr. ἀντι, *against*, and ἡλιξ *the helix*, or *external involute margin of the auricle*.) In Anatomy, the outer or external ridge of the auricle ear, which runs nearly parallel with the helix.

ANTHELMI'NTICS. (Gr. ἀντι, *against*, and ἕλμινς, *a worm*.) Medicines which kill intestinal worms, or effect their expulsion.

A'NTHEM. (Gr. ἀντιφωνη, *alternate singing*.) A piece of music performed in cathedral service by choristers who sing alternately. This manner of singing is very ancient in the church; some suppose it to have descended from the practice of the earliest Christians, who, according to Pliny, were accustomed to sing their Hymn to Christ in parts or by turns (*secum invicem*).

A'NTHER. (Gr. ἀνθηρα, *a flowery herb*.) A hollow case, usually consisting of two parallel cells, and constituting the apparatus that contains the pollen, or male part of a flower. Theoretically considered, an anther is the blade of a leaf, in a contracted state, with its two sides hollowed out and its parenchyma converted into pollen, while the midrib in a fleshy state divides the two lobes, and is called the connective. This part is sometimes highly developed, when the lobes of the anther are often placed at a distance from each other, as in Nymphæa; or it is altogether absorbed, when the lobes run together, and there is but one cell, as in Epacris. Other modifications produce other striking appearances: one lobe, for instance, disappears, and the connective is expanded into the state of a petal, as in Canna; or it is simply lengthened and distorted, as in Salvia; or, the anther remaining in its normal state, it is converted into a fleshy mass, as in Penæa; and it undergoes many similar transformations, either from the same or other causes. What is most curious about the anther, is its property of opening to discharge its pollen just at the very time when the stigma is ready to receive the influence of the latter. The cause of this sympathy between two really independent parts is supposed to consist in an emptying and drying up of the cellules forming the lining of the anther by the absorbent action of the ovary, which is imagined thus by its own efforts to bring about an action which is necessary to its own complete operation. The cellules lining the anther, when thus dried up, contract, and pull against certain fissures or dehiscent lines in the valves of the anther, which give way, and so form openings by which the pollen escapes.

ANTHERI'FEROUS. (Lat. anthera, *an anther*, and fero, *I bear*.) Forming a support to an anther.

ANTHERO'GENOUS. (Lat. anthera, and Gr. γείνομαι, *I am produced*.) When, in double flowers, the anthers are converted into horn-like petals, as in the double columbine.

ANTHE'ROID. Resembling an anther.

ANTHE'SIS. (Gr. ἀνθησις, *the generation of flowers*.) The period when flowers expand. It is as that time that all the curious phenomena of fertilisation occur; the parts are all in their most perfect state, and consequently it is often necessary to speak of that period.

ANTHO'DIUM. (Gr. ἀνθος, *a flower*, or ἀνθωδης, *full of flowers*.) The head of flowers of a thistle or a daisy; it is the same thing as capitulum, and is applicable to all cases where a number of small flowers or florets are combined in a head, and surrounded by a common involucrum. An anthodium is nothing but a depressed spike.

ANTHO'LOGY. (Gr. ἀνθολογια.) Signifying "a garland of flowers," and metaphorically applied to a collection of short pieces of poetry, on amatory, convivial, moral, funereal, &c. subjects, called epigrams; not in the English sense of the word, which implies a pointed conceit, but in the more proper signification of "inscription." The first collection of epigrams known by the name of Anthology was made by Meleager, a Syrian Greek poet, who lived about a century before the birth of Christ; and to this several additions were made by different hands as low down as the times of the Byzantine empire. A selection from the Greek Anthology, translated into English verse by the late Mr. Bland and several friends, has gone through two editions.

ANTHO'LYSIS. (Gr. ἀνθος, *a flower*, and λυσις, *a breaking up*.) The changes of flowers from their usual to some other state, as leaves, branches, &c.

ANTHO'PHORUM. (Gr. ἀνθος, *a flower*, and φερειν, *to bear*.) A columnar process arising from the bottom of the calyx, and having at its apex the petals, stamens, and pistil. It is usually very short, and is in reality an internode between the whorls of sepals and petals.

ANTHOXA'NTHUM. (Gr. ἀνθος, *a flower*, and ξανθος, *yellow*.) A dwarf annual grass, found plentifully in pastures, and having sweet-scented leaves. It is thought that the fragrance of hay is owing to its presence. The flowers are in oval heads, which become dull yellow when ripe. Farmers call it the sweet vernal grass.

ANTHOZA'SIA. (Gr. ἀνθος, *a flower*, and ζαω, *I flourish*.) When the leaves of a plant assume the appearance of petals.

AN'THRACITE. (Gr ἀνθραξ, *charcoal*.) Mineral carbon. A difficultly combustible species of coal.

A'NTHRACOTHE'RIUM. (Gr. ἀνθραξ, *charcoal*, and θηριον, *a beast*.) A name indicative of the stratum in which the fossil genus of Pachyderms, to which it is applied, was found, viz. in the tertiary coal or lignite of Cadibona, in Liguria. The genus presents seven species, some of them approximating to the size and character of the hog; others approaching nearly to the dimensions of a hippopotamus.

A'NTHRAX. The name of a Fabrician genus of Dipterous insects, having the mouth provided with a very long straight setaceous sucker, formed of two unequal horizontal valves, and containing setaceous stings; palpi two, hairy; antennæ distant, the last joint setaceous. The genus is now raised to the rank of a family, *Anthracidæ*, characterised by a short body; wings spreading widely out; antennæ distant, two and sometimes three jointed;

the head as high as the thorax. Two of the genera (*Somatia*, and *Anthrax* proper) are British.

ANTHRE'NUS. The name of a Linnæan genus of Coleopterous insects, having the antennæ clavate, the club solid; palpi unequal, filiform; maxillæ membranaceous, linear, bifid; labium entire; head hid under the thorax.

A'NTHRIBUS. The name of a Fabrician genus of Coleopterous insects, applied to that section of the Linnæan Curculiones, which has the lip bifid, the jaw bifid and short, and the proboscis short.

ANTHROPO'GRAPHY. (Gr. ἀνθρωπος, *man*, and γραφειν, *to describe*.) A branch of Physical Geography which investigates the physical characteristics, local boundaries, and actually existing circumstances, of different races or families of men: differing from Ethnography, which examines their origin and affinities.

ANTHROPO'LOGY. (Gr. ἀνθρωπος, *man*, and λογος, *discourse*.) The science which treats of human nature, both physical and intellectual: any writing on the nature and attributes of man may be said to be anthropological. But the term is frequently used to denote the science of Anatomy in particular.

ANTHRO'POMO'RPHITES. Persons who conceive the Deity to have naturally the human shape. Such sensuous conceptions of the nature of God have been always common among heathens.

ANTHRO'POMO'RPHOUS. (Gr. ἀνθρωπος, *a man*, and μορφη, *form*.) A name applied to the labellum in some Orchidaceous plants, in consequence of the upper lobes having a fancied resemblance to human arms, and the lower to human legs.

ANTHROPO'PHAGI. (Gr. ἀνθρωπος, *man*, and φαγειν, *to eat*.) People who feed upon human flesh.

ANTHU'RUS. (Gr. ἀνθος, *a flower*, and οὐρα, *a tail*.) A spike of minute flowers arranged closely on a long axis, as in the genus Piper.

A'NTHUS. The name of a subgenus of Passerine birds, including the pipits.

A'NTI. (Gr. ἀντι, *against*.) This Greek preposition is constantly used as a prefix; thus, antidote, antibilious, antipathy, &c.

A'NTIAR. (*See* Upas.) A Javanese poison.

A'NTI-ATTRI'TION. A compound applied to machinery to prevent the effects of friction. It frequently consists of a mixture of plumbago with some greasy material.

ANTIBRA'CHIUM. (Gr. ἀντι, *against*, βραχιον, *arm*.) The fore-arm, or third segment of the anterior extremities, which is formed, in the skeleton, by the radius and ulna conjointly; or sometimes by the radius, either alone, or with the ulna partially developed. And the fore-arm articulates, above with the arm, below with the hand.

A'NTICHAMBER. (Fr. antichambre.) In Architecture. Any outward chamber adjoining or near a bed-chamber; also an apartment before any principal chamber; also a lobby or outer waiting room in a palace.

A'NTICHRIST. (Gr. ἀντιχριστος, *opponent of Christ*.) Mentioned by St. John, 1st Ep. ii. 18., and supposed to be the same with the "man of sin" whose coming is foretold by St. Paul, 2d Thess. ch. ii. The speculations in which theological writers have indulged respecting this great adversary of Christianity have been various and most fanciful; but the prevalent opinion among reformed divines has always connected him with the Romish church. At the council of Gap, in 1603, the reformed ministers there assembled, inserted an article in their Confession of Faith, in which the pope is pronounced Antichrist. Grotius, and most catholic divines, consider Antichrist as symbolical of Pagan Rome and her persecutions: Leclerc, Lightfoot, and others, of the Jewish Sanhedrim, or particular Jewish impostors. (See Dodsworth's *Advent Lectures*, London, 1837, for the opinion entertained by some High Church divines of the present day.)

ANTICLI'MAX. (Gr. ἀντι, and κλιμαξ, *gradation*.) In Rhetoric, when a sentence or discourse, instead of ascending from little to great, descends from great to little. Horace has given a famous example,

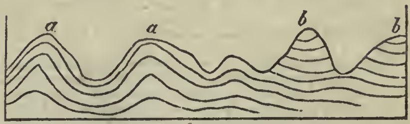
> "Parturiunt montes, nascetur ridiculus mus.'

There are also several striking examples of this figure in Pope, as in the verse,

> "Die, and endow a college or a cat."

But in this case the effect is heightened by the alliteration.

ANTICLI'NAL AXIS (Gr. ἀντι, *against*, and κλινειν, *to incline*.) If a range of hills or a valley be composed of strata which, on the two sides, dip in opposite directions, the imaginary line that lies between them, towards which the strata on each side rise, is called the anticlinal axis. In a row of houses with steep roofs facing the south, the slates represent inclined strata dipping north and south, and the ridge is an east and west anticlinal axis (Lyell). In the annexed diagram, *a a* are the anticlinal, and *b b* the synclinal lines.



ANTI'COUS. (Lat.) In Botany, is applied to an anther whose lobes are placed facing the style; or to a petal which is stationed on that side of a flower which is next the eye of an observer as it grows upon its stem.

ANTI'CUM. (Lat.) In ancient Architecture. The southern porch of a building; that which was towards the north being called the posticum. It is also used to signify that part of the temple between the cell and the columns of the portico.

A'NTIDOTE. (Gr. ἀντι, *against*, and διδωμι, *I give*.) A remedy or preservative against sickness.

A'NTIFI'XA, or ANTEFIXA. (Lat. ante, *before*, and figo, *I fix*.) In Architecture. The ornaments of lions' and other heads below the eaves of a temple, through perforations in which, usually by the mouth, the water is cast away from the eaves. By some this term is used to denote the upright ornaments above the eaves in ancient Architecture, which concealed the ends of the harmi, or joint tiles.

ANTILI'THICS. (Gr. ἀντι, *against*, and λιθος, *a stone*.) Medicines used in the treatment of stone in the bladder and urinary gravel.

A'NTILO'GARITHM. In its most common acceptation, denotes the number to a logarithm. Thus, in the common system of logarithms, 100 is the antilogarithm of 2, because 2 is the logarithm of 100. Sometimes the term is used to denote the complement of the logarithm, or the difference of the logarithm from the next higher term in the series, 1, 10, 100, &c.

ANTILOI'MIC. (Gr. ἀντι, *against*, and λοιμος, *contagion*, or *the plague*.) Remedies used in the prevention and cure of the plague.

A'NTILOPE. (Gr. ἀνθος, *ornament*, and ὠψ, *eye*.) Antelope; a term which, according to Cuvier, is a corruption of the word "antholops," applied by Eustathius, an ancient naturalist, to the gazelle, in allusion to its beautiful eyes. The name is now given to a division of the hollow-horned Ruminants (see Cavicornia), in which the bony axis of the horn is without cavities or sinuses. Antilopes are further distinguished by suborbital or maxillary glandular pouches, and their light and elegant figure. They are the natives, for the most part, of the wildest and least accessible places in the warmer latitudes of the globe; frequenting the cliffs and ledges of mountain rocks, or the verdure-clad banks of tropical streams, or the oases of the desert. They traverse the intervening wildernesses in pairs or in troops, with incredible fleetness, clearing obstacles, which would impede the course of other quadrupeds, by a succession of agile bounds.

The antilopes are now arranged under a number of subgeneric divisions, according to the form of the horns, which are peculiar to the male.

ANTIMO'NIC ACID. The peroxide of antimony. (*See* Antimony.)

AN'TIMONY. A brittle metal of a silver white colour; specific gravity, 6·7. Fuses at 810°, or just at a red heat. The principal properties of this metal were first described in the "Currus Triumphalis Antimonii" of Basil Valentine, published towards the end of the thirteenth century. When heated in an open vessel, it gradually combines with oxygen, and evaporates in a white vapour. There are three oxides of antimony. The protoxide consists of 65 antimony + 12 oxygen; it is a greyish white powder, eminently purgative, sudorific, and emetic; and as such, of much importance in medicine. It is the active base of emetic tartar and of James's powder. The other oxides of antimony, from combining with certain bases, have been called antimonious and antimonic acid; they consist respectively of 65 antimony + 16 oxygen, and 65 + 20. The combination of chlorine and antimony was known to the old chemists under the name of *butter of antimony*. The principal ore of antimony is the *sulphuret:* it is met with in commerce, melted into conical ingots, under the name of crude antimony. It is of a bluish grey colour, metallic lustre, and a striated texture; specific gravity 4·62; it is much more easily fusible than the pure metal. Antimony forms brittle alloys with some of the most malleable metals: when gold is alloyed with a two-hundredth part of antimony, the compound is brittle; and even the fumes of antimony in the vicinity of melted gold are sufficient to render it brittle. Alloyed with lead in the proportion of 1 to 16, and a small addition of copper it forms the metal used for printers' types: with lead only, a white and rather brittle compound is formed, used for the plates upon which music is engraved. With iron it

forms a hard whitish alloy, formerly called *martial regulus*: 12 parts of tin and 1 of antimony form hard pewter. The white metal spoons and teapots are formed of an alloy of 100 tin, 8 antimony, 2 bismuth, and 2 copper.

Antimony is the stimmi, or stibium, of the old chemists.

ANTINO'MIANS. (Gr. ἀντι, *against*, and νομος, *law*.) Oppugners of the law. In Theology, Antinomians are such as interpret the law, to which St. Paul refers more especially in the Epistle to the Romans, as including all moral ordinances whatsoever; and push the contrast which the Apostle maintains between faith and the works of the law to an extreme extent, asserting the entire uselessness of good works, in any case, and the sole efficacy of faith. Hence the term Solifidian is applied to the same class of religionists. The name of Antinomian was first given by Luther, as a term of reproach, to the followers of the opinions of John Agricola on this subject, who complained, however, that his notions had been unfairly represented. Similar doctrines appear to have been held in England by an ephemeral sect in the time of the commonwealth: but antinomianism may now be taken rather as expressing the extreme to which the Calvinistic scheme of theology has the tendency to lead men, than as denoting any distinct sect or congregation, either in this country or abroad.

ANTIPÆ'DOBA'PTISTS. In Theology. Those who object to the baptism of infants on the ground that they are not capable of understanding the nature of the rite, and of pledging themselves to such a course of life as is required of all such as come to be baptized. (*See* BAPTISTS.)

A'NTIPATHES. A genus of Corticiferous Polypes, or corals, in which the central axis is enveloped by so soft a cortex that it falls off when the specimen is removed from the water. From the colour of the axis, it is commonly called "black coral."

A'NTIPE'DES. (Lat. ante, *before*, pes, *foot*.) In Zoology, the anterior or pectoral extremities.

A'NTIPHLOGI'STICS. (Gr. ἀντι, *against*, and φλογισμος, *inflammation*.) Medicines which allay inflammatory action.

A'NTIPHLOGIS'TIC SYSTEM. In Chemistry, the system opposed to that of Phlogiston. (*See* PHLOGISTIC.)

A'NTIPHON. (Gr. ἀντιφωνειν, *to sing against*, or *mutually*.) In ancient Church Music, the short verse sung before the psalm and other portions of the Catholic service. (*See* ANTHEM.)

ANTI'PODES. (Gr. ἀντι, *against*, and πους, *the foot*.) Denotes, literally, those who stand feet to feet; that is, the inhabitants of opposite parts of the earth. They live under the same parallels of latitude, on opposite sides of the equator, consequently the seasons are reversed, or, when it is summer to the one, it is winter to the other. Their longitude differs by 180°, or 12 hours, consequently their days and nights are reversed, that is, when it is mid-day to the one, it is midnight to the other. They have the same climate, in so far, at least, as climate depends on latitude.

A'NTIPOPE. One that assumes the title and functions of pope without a valid election. The term more particularly refers to the popes who maintained themselves in opposition to each other, during part of the fourteenth and fifteenth centuries. The great western schism was caused by the rival jealousies of the French and Italian parties in the conclave; the French cardinals having been accustomed by their numbers, and the influence of the kings of France, to carry the election in favour of French candidates, while the popes resided at Avignon, a period of about 70 years, from 1305 to 1376. Accordingly, when the Italian party at last succeeded in the election of Urban VI., in 1389, the French cardinals retired from Rome, and there invested with the functions of pope one of their own body, under the title of Clement VII. They attempted, in the first instance, to maintain themselves in Italy, and war was proclaimed between the two rivals. After a short struggle, Clement retreated to Avignon; and there he, and his successor, Benedict XIII., held their court, while Urban, and after him, Boniface IX. and Gregory XII., reigned at Rome. They were supported respectively by different European states, of which France, Austria, Castile, Aragon, Savoy, Genoa, and Scotland sided with the party of the seceders. The schism, however, caused great scandal throughout Christendom, and measures were repeatedly taken, and baffled only by the artifices of the rival claimants, for an adjustment of the difference. There seemed to be three methods of proceeding to this end, and each liable to great difficulties:—1st. By the simultaneous resignation of both pontiffs, and a fresh election. 2d. By an arbitration between them. And, 3d. By the calling of a general council, to declare the holy see void, and recommend the conclave to fill the vacancy. This last method was finally adopted; though it has been constantly objected, that such a council could not be lawfully convened except by the summons of a reigning pope; which condition certainly was not fulfilled in the instance of the council of Pisa. However, in 1409, the rival parties were both declared guilty of heresy and schism, and thereby the validity of both claims greatly disproved. Alexander V. was then elected in due form; and the antipopes were unable long to maintain their pretensions against the authority of a general council.

A'NTIQUARY. Copiers of old books, especially in convents, were termed *Antiquarii* in the Latin of the middle ages. In modern phraseology, antiquary is defined "a person who studies and searches after monuments and remains of antiquity, as old medals, books, statues, inscriptions, &c.;" to which may be added those who make the manners and customs of ancient times an especial subject of inquiry. Henry VIII. gave Leland the title of his "Antiquary." The Royal Society of Antiquaries, in London, was founded under the reign of George II. (*See* ACADEMY.)

ANTI'QUE. In a restricted sense, pieces of ancient art, and by artists usually confined to such as were made by the Greeks and Romans of the classical age.

ANTI'QUITIES. Under this term, which has not a very definite meaning in modern European languages, we appear generally to comprehend all memorable things respecting Man in his social state in past time, except the political events, which form more properly the subject of History. Thus, manners and customs, language, literature, topographical details, the monuments of architecture, sculpture, &c. of ancient times, all fall under the general cognizance of the antiquary. His science is, as it were, subsidiary to the more general objects of the historian. In a more restricted sense, the study of antiquities is confined to the description and interpretation of the existing relics of former times, such as architectural remains, manuscripts, medals, and other objects of curious research. Among classical writers, there is, perhaps, only one who falls exactly within the definition of what in modern times we should term an antiquary; viz. Pausanias, whose work, written about the period of Marcus Antoninus, is entirely devoted to a description of the monuments of earlier periods then existing in Greece. But about the time of the revival of letters, when the study of classical writers became the main pursuit of literary men, classical antiquities became also a distinct and important branch of research. Besides the writers who employed their antiquarian knowledge in the shape of commentary on classical authors, a great number devoted their talents to the production of treatises exclusively illustrating particular points in ancient customs and usages. To enumerate the chief classical antiquaries of the 16th and 17th centuries would be impossible; but the following works may be named as among the most comprehensive and general which we possess, containing an immense repository of facts, which the more refined criticism of modern times has sifted and applied with better success: the treatises of *Signonius* and *Meursius*—the latter chiefly on Greek antiquities—are collected in 12 folio volumes, Florence, 1741; the vast *Thesaurus Antiquitatum Græcarum* of the Dutch commentator Grævius (Leyden, 12 vols. fol. 1697, &c.); and the still more extensive work of Gronovius (*Thesaurus Antiquitatum Romanarum*, Leyden, 13 vols. fol. 1697), together with its continuations and supplements, by Burmannus, extending in the whole to 45 volumes; The works of Polenus, Pitiscus, and Gruterus, on the same plan with those two vast collections; the *Antiquité Expliquée* of Bernard de Montfauçon, extending, with the supplements, to 15 vols. folio, Paris, 1719-24. From these great works our modern Compendia in common use (in English, the Grecian Antiquities of Archbishop Potter, the Roman Antiquities of Kennett, Adam, &c.) are chiefly compiled. The names of Boeck (*Public and Private Economy of Athens*), Heeren (*History of Ancient Commerce, &c.*), Müller, Niebuhr, Creuzer, Böttiger, Wachsmuth, &c., attest the equal industry and superior critical skill of the classical antiquaries of modern Germany, the only country in which this branch of knowledge is now successfully cultivated. In that more restricted branch of classical antiquities, the description of the monuments of ancient art, among many illustrious names we may mention those of Caylus (*Recueil d'Antiquités Egyptiennes, Grecques, et Romaines*, 7 vols. 4to. Paris, 1752, &c.) and the Abbé Winkelmann. In the peculiar study of Egyptian antiquities, the names of Young, Hamilton, and Champollion stand pre-eminent. In ecclesiastical antiquities, the huge collections of Ugolinus (*Thesaurus Antiquitatum Sacrarum*, 34 t. fol. Antv. 1744) and Canisius (*Lectiones Antiquæ*, edited by Basnage, 4 t. fol. v. Antv. 1725) may be mentioned among many others. Lastly, the antiquities of the middle ages have received much and accurate attention, especially in France and England, within the last century. Besides the works of Leland and Camden, the fathers of English antiquities, of Dugdale and Hearne, &c., we may name, in modern times, Fosbrooke (*British Monachism*, 2 vols. 4to. 1802, and *Encyclopædia of Antiquities*), Strutt (*Regal and Ecclesiastical Antiquities of England*, 4to.

1773, and many subsequent works), Brand, Lodge, Playfair, &c. &c., besides many who have devoted themselves to particular branches of the subject; and, among living authors, Sir Henry Ellis, Sir F. Palgrave, Sir H. Nicholas, Mr. Petre, &c. In French antiquities, the greatest name is that of Montfaucon (*Monumens de la Monarchie Française*, 5 vols. fol. Paris, 1725, &c.); while the Italians, among whom the study of national antiquities has been very sedulously cultivated, are peculiarly indebted to the indefatigable Muratori. His principal works are the *Antiquitates Italicæ Medii Ævi*, and *Rerum Italicarum Scriptores*: the whole are said to amount to 41 vols. in folio, besides 34 in 8vo.

ANTIRRHI'NEÆ. A small division of Scrophulariaceous plants, consisting of *Antirrhinum* (the snapdragon of the gardens), Linaria, and a few other genera.

ANTI'SCII, or ANTISCIANS. (Gr. ἀντι, *against*, and σκια, *shadow*.) An old term used in Geography to denote those inhabitants of the earth whose shadows fall in opposite directions. The inhabitants of the north and south temperate zones are always Antiscians; those living within the tropics may be Antiscians at one season of the year, and not at another.

ANTISCORBU'TICS. Medicines against the scurvy.

ANTISE'PTIC. (Gr. ἀντι, *against*, and σηπειν, *to putrefy*.) Antiputrefactive. Substances which prevent or check the putrefaction and decay of animal and vegetable matter, are called antiseptic.

ANTISPASMO'DICS. (Gr. ἀντι, *against*, and σπασμος, *a spasm*.) Medicines which alleviate or cure cramp and spasm.

ANTIS'TROPHE. See STROPHE.

ANTI'THESIS. (Gr. ἀντι, and τιθεναι, *to set*.) In Rhetoric, a figure in which two thoughts, words, or sentences are set in opposition to each other, in order to be more strikingly brought forward by the contrast; as in the following sentence from Cicero: "Quod scis, nihil prodest: quod nescis, multum obest." "Your knowledge avails you nothing: your ignorance hurts you much." Quintilian translates the Greek word ἀντιθεσις by the Latin *contrapositum*. The following well known passage of Spenser may be cited as an instance of mixed antithesis and accumulation.

> "Ah! little dost thou know, that hast not tried,
> What hell it is in suing long to bide;
> *To speed to-day, to be put off to-morrow:*
> *To feed on hope, to pine with care and sorrow:*
> *To have thy prince's grace, yet want her peer's:*
> *To have thine asking, yet wait many years:*
> To fawn, to crouch, to wait, to ride, to run,
> To spend, to give, to want, to be undone."

ANTI'TRAGUS. (Gr. ἀντι, *against*, τραγος, *the marginal process of the external ear which is immediately in front of the meatus*.) In Anatomy, the process of the external ear opposite the tragus, and behind the meatus auditorius, or ear-passage.

ANTI'TROPAL. (Gr. ἀντι, *opposite*, and τρεπειν, *to turn*.) When in a seed the radicle of the embryo is turned to the end farthest away from the hilum. This, although a comparatively unusual position of parts, is nevertheless the normal position, if the exact nature of the developement of an ovule is rightly understood.

A'NTLIA. The oral instrument of Lepidopterous insects, in which the ordinary trophi, or instruments for obtaining, are replaced by a spiral, bipartite, tubular machine for suction, with its appendages. It principally consists of the solenaria, or two lateral subcylindrical tubes, and the fistula, or intermediate subquadrangular pipe, formed by the union of the two solenaria, which intermediate canal conveys the nectar to the pharynx. Theoretically, the solenaria are the maxillæ inordinately elongated, and they support at their bases two minute palpi. Rudiments of the upper lip or labrum, and mandibles, exist above the maxillæ; and below these is the labrum, attached to the head, and distinguished by a pair of large palpi.

ANTLIA PNEUMATICA. A constellation of the southern hemisphere.

ANTŒ'CI. (Gr. ἀντι, *opposite*, and οἰκος, *a house*.) Those who live over against each other; a term used in Geography to denote the inhabitants of the globe who live under the same meridian, but on opposite parallels of latitude. The hours of the day or night are the same to each, but the seasons of the year are opposite; that is, when it is summer with the one, it is winter with the other.

A'NTONOMA'SIA. (Gr. ἀντι, *instead of*, and ὀνομα, *a name*.) In Rhetoric and Composition, a figure by which a proper name is put for an appellative noun; as where a tyrant is called a Nero, an usurper a Cromwell, &c.: or, vice versâ, a complimentary periphrasis, or an appellation derived from some attribute, is put for a proper name; as where a king is called "His Majesty," or Tacitus "the prince of political historians."

A'NTRUM. (Lat. antrum, *a cave*.) An old name applied to such hollow fruits as the apple; they are now called Pomes.

ANTRU'STIONS, otherwise styled Fideles (Faithful) and Leudes (Leute, Germ. *people*). A class of people among the Franks, who were the personal vassals or dependents of the kings and counts. They were not dependent on them by reason of holding lands by their grant: but rather, in consequence of being such dependents, were favoured with donations of land, or benefices; which, in process of time, becoming hereditary, assumed the character of Fiefs. (See FEUDAL SYSTEM.) The original word from which Antrustion is derived, was undoubtedly the same with that from which our word *trust*, confidence, has its descent.

ANU'BIS. In Mythology, an Egyptian deity. The seventh, according to the astronomical Theology, of their eight gods of the first class. The Greeks identified him with Mercury. In Egyptian painting and sculpture he is represented as a man with the head of a dog: whence the lines in the 6th book of Virgil's Æneid, describing the conflict of Egypt with Rome:—

> Omnigenûmque Deûm monstra, et latrator Anubis,
> Contra Neptunum et Venerem, contraque Minervam,
> Tela ferunt.

A'NUS. The excrementary orifice of the alimentary canal, which sometimes opens directly on the exterior surface of the animal, as in most Mammals; sometimes into a cavity common to it with the outlets of the urinary and genital organs, called the cloaca, as in most oviparous Vertebrates; sometimes into the respiratory cavity, as in most Mollusks. In Entomology, it signifies the two last segments of the abdomen, and includes the podex, hypopygium, culus, ovipositor, and appendices. In most of the Acrites there is but one orifice to the alimentary cavity, which thus combines the functions of mouth and anus.

A'ORIST. (Gr. ἀοριστος, *indefinite*.) That inflexion of the verb which leaves the time of the action denoted uncertain.

AO'RTA. (Gr. ἀηρ, *air*, and τηρειν, *to keep*.) The great arterial trunk which issues from the left ventricle of the heart. After death it is found empty; whence the older anatomists, supposing that it was for the conveyance of air, gave it the above name. It is single in Mammals and birds; double in most reptiles, and in the Cephalopods; triple in the Crustaceans.

APA'GYNOUS. (Gr. ἁπαξ, *once*, and γυνη, *a female*.) When a plant fructifies but once, perishing immediately after it flowers. It is the same as monocarpic, and nearly the same as annual; only that, like the latter term, it includes such plants as the American agave, which live many years before they fructify.

A'PALUS. A Linnæan genus of coleopterous insects, having the antennæ filiform; the palpi equal and filiform; the maxillæ horny and one-toothed; the labium membranaceous, truncate, and entire.

A'PANAGE. An allowance to younger branches of a sovereign house out of the revenues of the country; generally together with a grant of public domains. A district with the right of ruling it, when thus conferred, is termed paragium. An apanage, in ordinary cases, descends to the children of the prince who enjoys it.

A'PATITE. Native phosphate of lime (from ἀπαταω, *I deceive*), having been confounded with other minerals.

APATU'RIA. An Athenian festival, which came also to be observed by the rest of the Ionians except those of Colophon and Ephesus. Two accounts are given of its origin: one of which derives its name from the Greek word ἀπατη, *deceit*, because it was instituted in memory of a stratagem by which Melanthus the Athenian king overcame Icanthus king of Bœotia; the other from πατηρ, *father*, and the prefix ἁ, signifying *together*, because at this festival children accompanied their fathers that their names might be entered on the public register. The festival took place in October, and continued three days.

APE. In the Zoological sense, is restricted to those higher organised species of the Linnæan *Simiæ* which are destitute of a tail. They are included in the modern subgenera, *Pithecus*, *Troglodytes*, and *Hylobates*, or the ourangs, chimpanzees, and gibbons.

APE'LLOUS. (Gr. ἀ, priv. and pellis, *skin*.) Destitute of skin.

APE'TALOUS. (Gr. ἀ, priv., πεταλον, *a petal*.) When a flower has a calyx only, and no corolla. The term is sometimes extended to those cases in which there is neither calyx nor corolla; thus, the apetalous plants of Jussieu are either destitute of a corolla only, or of all floral envelopes of whatever kind.

A'PEX. The summit or highest point of any thing. Thus, the apex of a cone, of a pyramid, &c.

APHÆ'REUS. (Gr. ἀφαιρειν, *to take away*.) In Writing or Pronunciation, the removal of a vowel from the commencement of a word; as, in English, 'it is' is sometimes written ''t is,' abide is changed into ''bide,' &c.

APHANI'PTEROUS, APHANI'PTERA. (Gr. ἀφανης, *obscure*, πτερον, *wing*.) The name of an order of Apterous Haustellate insects, having rudimental elytra or wings in the perfect state, and undergoing a metamorphosis, resembling that of the *Tipulidæ*, or crane-flies. The common flea (*Pulex irritans*, Lin.) may be regarded as the type of this order. The female flea (*Pulex irritans*, Lin.) deposits a dozen eggs, of a white colour and rather

viscous texture, from which proceed little apodal maggots, which are very active in their motions, winding themselves in a serpentine manner through the substance in which they may be deposited: the head of the larva is protected by a firm skin, and bears two small antennæ, but no eyes; the body consists of thirteen segments, bearing little tufts of hair, and the last is armed with a pair of hooklets: the mouth presents some small moveable instruments with which the maggot hauls itself along. After having passed twelve days under this form, the larva spins itself a little silken cocoon, in which it passes into the pupa state, and in about twelve days more emerges a perfect flea; this metamorphosis distinguishes the flea and chigoe from other blood-sucking parasitic Apterous insects; and they are further distinguished by the number of segments into which their body is divided, and their pentamerous, or five-jointed, tarsi.

APHE'LION. (Gr. ἀπο, *from*, and ἡλιος, *the sun.*) In Astronomy, is that point of a planet's orbit which is at the greatest distance from the sun. It is opposed to perihelion, which signifies the point of the orbit nearest the sun. The aphelion and perihelion of an orbit are consequently the two extremities of its greater axis. In consequence of the mutual attractions of the planets, the positions and figures of their orbits are constantly undergoing a slow variation. The aphelia gradually shift their places on the planes of the orbits; and it is remarkable that these motions are direct, or eastward, in the case of all the planets excepting Venus, the aphelion of whose orbit, when referred to the fixed stars, moves westward at the rate of about 4 seconds annually. Of the old planets, Saturn is that whose aphelion undergoes the greatest annual variation; it amounts to about 18 seconds of a degree. (*See* PERIHELION, PLANET.)

APHE'LXIA. (Gr. ἀφελκειν, *to abstract.*) Absence of mind.

APHE'RESIS or APHÆ'RESIS. (Gr. ἀφαιρεσις, from ἀφαιρεω, *I take away.*) In Grammar, a figure by which a letter or a syllable is cut off from the beginning of a word; as in the common abbreviation, "'t is," for "it is."

A'PHIDES. (Gr. ἀφις, *a puceron*, or *vine-fretter.*) A family of Hemipterous insects, commonly called "plant-lice," inhabiting trees and plants, and living on their juices; remarkable for the anal saccharine secretion referred to in ANAL GLANDS, but more especially for a peculiarity of their generative economy, particularly described by Bonnet, and which consists in the first fecundation of the female influencing not merely the ova immediately developed thereafter, but those of the females resulting from that developement, even to the ninth generation, which are successively impregnated and productive without any intercourse with the male insects. Certain Coleopterous insects, which prey upon and keep in check the Aphides, are termed Aphidiphagi and Aphidivora (φαγω, *I eat*, voro, *I devour*).

APHLOGI'STIC. (Gr. ἀφλογιστος, *uninflammable.*) Without flame or fire.

APHLOGI'STIC LAMP. A lamp with a glowing wick, the combustion in which goes on without flame.

A'PHONY. (Gr. ἀ, priv., and φωνη, *voice.*) Loss of voice.

A'PHORISM. (From the Greek ἀφοριζειν, *to define*, or *limit.*) A term chiefly used in Law and Medicine, but occasionally also in Moral Philosophy, &c., to denote a comprehensive maxim or principle expressed in a few words.

APHRI'TE. (Gr. ἀφρος, *froth.*) A soft, friable carbonate of lime.

APHRODI'SIAC. (Gr. 'Αφροδιτη, *Venus.*) That which incites to venery.

APHRODI'TE. (Gr. 'Αφροδιτη, the name of *the Goddess of Love*, having reference to her supposed origin from the *foam of the sea*, ἀφρος.) This classical name was applied by Linnæus to a beautiful genus of Annelidans adorned with resplendent silky hairs and bristles, of which the sea-mouse (*Aphrodita aculeata*, Lin.) of our coasts is an example.

APHRODI'TIDÆ. The name of the family of Annelides of which the Aphrodita aculeata is the type.

APHYLLA'NTHEÆ. A small division of the Juncaceous order of Endogens, comprehending the genus Aphyllanthus from the South of Europe, with Calectasia and Dasypogon from New Holland.

APHY'LLOUS. (Gr. ἀ, priv., and φυλλον, *a leaf.*) Leafless. The term is, however, often applied to plants in which the leaves are present, but so small as not to look so much like leaves as mere scales. Plants are also called leafless, in which, although scales of considerable size are present, there are no true green leaves: of this description are Monotropa, Orobanche, Pyrolaaphylla, &c.

APIA'CEÆ. (Lat. apium, *parsley.*) A name recently proposed to replace that of Umbelliferæ, it being constructed with more resemblance to the plan upon which the names of other natural orders are formed in Botany, than that of Umbelliferæ.

A'PIARY. (Lat. apis, *a bee.*) A place for keeping beehives. Sometimes this is a small house, with openings for the bees in front, and a door behind, which is kept locked for security; and sometimes it is an area, in which each particular beehive is chained down to a post and padlocked.

API'CULATED. (Lat. apex, *a sharp point.*) When a leaf or any other part is suddenly terminated by a distinct point.

A'PIDÆ. (Lat. apis, *a bee.*) One of the varieties resulting from the modern division of the Linnæan genus *Apis*, including those species which are distinguished by the length of the terminal parts of the inferior organs of the mouth, which constitute a proboscis.

APIO'CRINITES. (Gr. ἀπιον, *a pear*, κρινον, *a lily.*) Pear Encrinite. (*See* ENCRINITE.) The name of a subgenus of fossil Encrinites, in which the body is formed of separate pieces articulated with the stem, and supporting the rays by similar articulations, in consequence of which the stem is rounded and dilated into a pyriform figure at its upper part.

A'PION. A genus of minute Coleopterous insects, of the weevil family (*Curculionidæ*); very numerous in species; distinguishable by their elegant pear-shaped form, protruded snout, and straight antennæ.

A'PIS. In Mythology, a bull, to which divine honours were paid by the Egyptians, especially at Memphis. He was required to be black, with peculiar spots and marks. One of this description was always maintained; but not suffered to live beyond twenty-five years. He was then buried with much solemnity; and Belzoni was of opinion that the bones discovered in one of the sarcophagi disinterred by him, belonged to such an animal. The outrage made by the Persian conqueror Cambyses on the bull Apis, and the disasters which were supposed to have befallen him in consequence of that act, are detailed in the history of Herodotus, book ii.

APIS. (Lat. apis, *a bee.*) The Linnæan genus, now subdivided into different families, is thus characterised: mouth horny; jaw and lip membranaceous at the tip; tongue inflected; feelers four, unequal, filiform; antennæ short, filiform, those of the female subclavate; wings flat; sting of the females and neuters pungent, and concealed in the abdomen.

The insects of this extensive genus live, some of them, in large societies, and some are solitary; their food is the nectar of flowers, honey, and ripe fruit; the larva is soft and without feet; the pupa resembles the perfect insect.

The characters of the Linnæan genus are applicable to a variety of forms, now the types of numerous subgenera, included by Latreille in a family of Aculeate Hymenopterous insects, under the term Anthophila, or Mellifera. The habits of each of the subgenera of this family are replete with interest, arising from their social economy, and the separation of the individuals into three sexual modifications, viz., the prolific females, or queens; the unprolific females, or workers; and the males, or drones. The policy of the hive-bee (*Apis mellifica*, Lin.) has been studied with so much diligence and detail, that we penetrate this mystery of nature with astonishment, and often feel inclined to regard what Huber relates, as fabulous. Nevertheless, the highly interesting observations of the writer, and those especially on which his reputation chiefly rests, have been confirmed by subsequent observers, both scientific entomologists as well as practical apiarians.

The hive-bee is distinguished from all other species of the modern genus Apis, by having the femora of the posterior pair of legs furnished with a smooth and concave plate on the outer surface, and fringed with hair, forming a basket adapted for the conveyance of pollen; and in being destitute of spines at the extremity; by the basal joint of the tarsi, in the workers, being of an oblong form, with its inner surface clothed with hairs disposed in transverse rows; by the trophi being of an elongated form, and the maxillary palpi being almost obsolete and consisting of a single joint.

The different individuals of the social Apis mellifica more nearly resemble each other in their grade of developement—as regards their locomotive powers, organs of sense, and instinctive endowments — than the ants. No individual among them is without wings; and the industry of the workers, or imperfect females, is less astonishing, at least their tasks are less arduous, than fall to the lot of the Apterous labourers of the ant tribes.

As bees, like most other winged insects, are annuals, or go through the whole essential economy of their existence within the year, the history of a year's existence includes the whole, and we have only to choose the point in the circle at which to commence it.

As some individuals, however, always survive the winter, and begin to breed early in spring, forming a colony which quits the parent stock, we shall begin with this colony, and trace their operations through the year.

The first young swarm in this country is generally sent off in June. The migration seems to depend on want of space in the mother-hive, not on an instinctive desire of change on the part of the brood; for if there be space for the operations of the increasing community, bees will not

naturally swarm; and skilful apiarians sometimes take advantage of this circumstance, and, by making successive additions to the hive, retain the whole year's increase in the same building. The swarm consists in general of about six or seven thousand individuals, of which about 1-30th part are males, the rest females; and of these, one only, for the most part, is prolific, and she is called the queen. Her body is longer than that of either the drone or worker; her colours are brighter and purer, and generally of a darker shade; the transverse bands across the abdomen are of a deeper and brighter yellow, and are sometimes orange; the head is smaller than that of the unprolific female, and the tongue is shorter and more slender; her mandibles are notched, and her sting is curved; but the most obvious distinctive character is the proportional length of the abdominal segment of the body, which lodges the generative apparatus, and which is of an elongate conical form, tapering rather sharply to the anus. The male bee is readily distinguished by the short and thick form of his body, which is obtuse at each extremity. He has no sting. The workers, like the queen, are armed with a sting, but it is straight, and proportionally larger and stronger. The workers are essentially females in their internal structure, but their growth is arrested before arriving at the period when the full development of the sexual system takes place, and they consequently are smaller than either the queen or the drones; and their colours are less bright. According to Huber, there are two varieties of labourers, one of a larger size, which he calls 'abeilles cirières,' or makers of wax; the other, or smaller variety, he terms 'abeilles nourrices,' or nurse-bees, whose crop, or first stomach, is not capable of the distention requisite for collecting honey, but whose office is to build the combs and cells after the foundation has been laid by the cirières, and to feed the larvæ.

It is also stated there are two kinds of drones; one not larger than the workers, the other as above described. And Huber has described another variety of the inmates of the hive, which he terms 'black bees,' and which are supposed to be the superannuated workers.

The swarm, thus composed, commonly leaves the hive in the heat of the day, and often immediately after a shower. It is supposed that the queen takes the lead; and she ever afterwards exercises an inscrutable influence over all their operations. Perhaps a stronger proof that instincts do not necessarily depend on physical conformation is not afforded by any phenomenon in natural history, than by the effects which the loss or death of the queen produces on the labourers: this event does not deprive them of any organ, or paralyse any limb; yet, the moment they are conscious of her loss, all their labours are interrupted and forsaken, and, unless another queen be provided, they join another hive, or perish from inanition.

The flight of the swarm is directed to some neighbouring fixed place, and wherever the stand is made they all forthwith repair to it. In the wild state, the cavity of an old tree is commonly chosen; and this, with a seeming prudence and foresight which cannot be sufficiently admired. The first care of the bees is to cleanse it from dust and rubbish, and to gnaw off with their mandibles any asperities or projections which might interfere with the future construction of the comb. In the state of domestication in which the hive-bee is usually preserved in this country, the practice of the above instinctive actions is rendered unnecessary, by the reception of the swarm into neat artificial hives. Yet this modification of their habits, and many other interferences to which they are subject, have had no effect in inducing any varieties in the organisation of the bee, nor any change in those instinctive actions which the care of man has not rendered indispensible. The consideration of this curious exception to the ordinary consequences of domestication, and of the conditions on which the circumscribed limits of variation in the bee depend, would lead us far beyond the extent allotted to the present subject; but it is an inquiry full of interest in relation to the recondite laws which govern the variation of animals from their specific standard.

In the wild state, the young colony at first return occasionally to the parent establishment for supplies of provision; and the domesticated bees always fill their crops with honey before they leave the hive. The wax is a peculiar secretion from the working bee; and having the materials, therefore, within themselves, they immediately begin to form the comb.

Before describing the many-chambered nursery and storehouse which our bees are about to prepare, a few words are necessary regarding the material of which it is constructed.

The formation of the wax is a very singular and complex operation. Huber says, "The wax-makers, having taken a due portion of honey or sugar, from either of which wax can be elaborated, suspend themselves to each other, the claws of the fore legs of the lowermost being attached to those of the hind pair of the uppermost, and form themselves into a cluster, the exterior layer of which looks like a kind of curtain. This cluster consists of a series of festoons or garlands, which cross each other in all directions, and in which most of the bees turn their back upon the observer: the curtain has no other motion than what it receives from the interior layers, the fluctuations of which are communicated to it. All this time the nurse-bees preserve their wonted activity, and pursue their usual employments. The wax-makers remain immoveable for about twenty-four hours, during which period the formation of wax takes place, and thin laminæ of this material may be generally perceived under their abdomen. One of these bees is now seen to detach itself from one of the central garlands of the cluster, to make a way amongst its companions to the middle of the vault or top of the hive, and by turning itself round to form a kind of void, in which it can move itself freely. It then suspends itself to the centre of the space which it has cleared, the diameter of which is about an inch. It next seizes one of the laminæ of wax with a pincer formed by the posterior metatarsus and tibia, and drawing it from beneath the abdominal segment, one of the anterior legs takes it with its claws and carries it to the mouth."

The wax has, perhaps, the nearest analogy to the sebaceous secretion of the integument, than to any other animal secretion: it is formed beneath the scales on the under side of the abdomen, and when accumulated there seems to irritate the part, for the bee may then be observed wagging her abdomen, and running round, or to and fro, as if endeavouring to shake out the little scales; and she is generally followed by one or two other bees, which have been attracted by her movements, and are ready to seize upon the plates of wax as they fall. How the bees mould the scales into the walls of the cells is not yet exactly understood. Some have supposed that they bite pieces off and join them together; but the smooth and uniform surface of the cell shows that some other operation must take place: besides, the wall of the cell is sometimes thicker than a scale of wax. We must, therefore, suppose that the bees have the power of applying some dissolving or softening menstruum to the wax-scales, by which they are enabled to knead and blend them into a ductile paste. And when we remember that the secretion of the salivary tubes of insects is generally alkaline, and that wax is best dissolved by alkali, it is reasonable to suppose that it is by this means that the wax-scales are brought into a workable state. Reaumur, indeed, observed a frothy substance exuding from the mouth of a bee while working at a cell, which was applied to the proper place by the nimble tongue, and then kneaded in by the mandibles; and Huber has described the process very circumstantially: he says that the bee holds the lamina of wax with its claws vertically, —the tongue rolled up serving for a support,—and by elevating or depressing it at will, causes the whole of its circumference to be exposed to the action of the mandibles, so that the margin is soon gnawed into pieces, which drop, as they are detached, into the double cavity, bordered with hairs, of the mandibles. These fragments, pressed by others newly separated, fall on one side of the mouth, and issue from it in the form of a very narrow riband. They are then presented to the tongue, which impregnates them with a frothy liquor. During this operation the tongue assumes all sorts of forms: sometimes it is flattened like a spatula; then like a trowel, which applies itself to the riband of wax; at other times it resembles a pencil, terminating in a point. After having moistened the whole of the riband, the tongue pushes it so as to make it re-enter the mandibles, but in an opposite direction, where it is worked up anew. The liquor mixed with the wax communicates to it a whiteness and opacity which it had not before, and doubtless gives it that ductility and tenacity which it possesses in its perfect state.

Bees commonly begin at the top or roof of their chamber, and build downwards, at first working irregularly, and as it were pasting over the surface; and then building horizontal cells of a more perfect form. These at length become so numerous, that they extend downwards in the form of a vertical wall; other congeries of cells are formed in succession, until the whole comb assumes the form of a series of perpendicular plates or partitions. Each plate consists of a double set of cells, the bottoms of which are applied to each other, and form the partition between each set. The plates are not always regular, and the irregularities which may be observed are not always necessary adaptations to a peculiar form of the cavity in which they are built. The cells are not all of the same size; but a sufficient number of a given depth are reserved for receiving the eggs, and which are necessarily adapted to the size of the future maggot: the smaller or shallower cells are those in which the honey is stored. The breeding and store cells are placed horizontally, but the mouth of the cell is sometimes a little raised—the better to retain the honey. The interspace between the vertical combs is generally about half an inch; these streets, as

they may be termed, in this city of industry, being just wide enough to allow two bees busied upon the opposite cells to pass without incommoding each other. In addition to these interspaces, the combs are perforated in various places, so as to allow a passage for the bees from one street to another, thus saving them much time.

The shape of each cell is not, as might have been expected, cylindrical, or that which seems best adapted to the form of the maggot, or even of the bee constructor; but it is hexagonal, — the only form which allows the cell to be of the largest size in proportion to the quantity of matter employed, and at the same time to be so disposed as to occupy in the hive the least possible space. The form of the base of each cell, which is in apposition with the one on the opposite side, is also such as to gain greater strength, and more capacity, with less expenditure of wax; the latter consideration being one of great importance to bees, which do not secrete a very large quantity of this material; and the most profound mathematicians and most skilful geometers have found the solution of the problem, relating to the attainment of the preceding objects, as derived from the infinitesimal calculus, to have a surprising agreement with the actual measure of the different angles formed by the walls of the cell.

There may generally be observed one or more cells, wider and shallower than the rest, placed either on the edge of a comb, or partition; or placed against the mouths of the cells, and projecting beyond the general surface of the comb. — These are called the royal cells; but as they are not adapted to the form of the queen, nor ever lined with the silken covering of the chrysalis, the supposition that the queen is bred in them seems improbable.

Having now generally described the comb, we return to the consideration of those instinctive operations by which its several compartments are furnished with their destined contents.

The comb seems at first to be formed entirely for propagation, and, indeed, to be essentially related to that function; for if the workers lose their queen, they make no combs; and the reception of honey is, therefore, its secondary use. Wasps and hornets make combs, although they collect no honey.

As soon as the young colony has prepared a few combs the female begins to exclude her eggs. The first that she lays produce the imperfect females, or workers; the subsequent ones produce the males, and, perhaps, the fertile females, or queens. The eggs are deposited at the bottom of the cells, often before these are half completed; they adhere generally by one end to the cell. In about five days the little maggot is hatched, and is seen lying at the bottom of the cell, coiled up in a transparent fluid.

Now begins the additional employment of the labourers, that of feeding and nursing the young maggots; for this purpose new materials must be collected abroad, and brought into the hive.

At first the bees of a young colony fly out singly, and afterwards collectively. They direct their flight generally in a straight line, or the nearest way to the destined object, and often travel to great distances from the hive. In summer time they may be seen almost every where where flowers bloom. In April and May they are abroad the whole day; but in the hot months they venture out less frequently, generally in the morning and evening, at which times it is more easy for them to form the pellets of the pollen, the grains of which adhere together less strongly during the heat of noon-day.

Bees do not like wet weather; yet it is, perhaps, less the presence of rain, than the changes in the degree of light, which deters them from venturing abroad at this time: for they possess large and complex organs of sight, and when clouds collect quickly over the clear sky, they are seen to hurry back in great numbers to the hive; while, if the sky be uniformly overcast, it is not merely a shower of rain that will drive them back: many of the actions of the bee prove, on the contrary, how essential moisture is for them. The bee does not take honey indiscriminately from every flower; in the meadows they may be seen generally upon the Orchideæ, Polygonia, Caryophylacea, but seldom, if ever, upon the Ranunculaceæ, perhaps on account of some poisonous quality. The oleander (*Nerium oleander*, L.), which yields poisonous honey fatal to thousands of flies, is carefully avoided by bees; and the crown imperial (*Fritillaria imperialis*, L.), the white nectaries of which are so conspicuous, tempts in vain the passing bee. They are, however, extraordinarily active in spring at the blossoming of the Amentaceæ, Rosaceæ (especially the dog-rose), and the balsamic lilies, Primulaceæ, &c.; and are, above all, allured by the innumerable flowers of the lime (especially *Tilia parvifolia*), and their hum may be heard among the branches at some distance. The finest flavoured and most delicate honey is collected from aromatic plants; and it is therefore always advisable to have large beds of borage, mignionette, lemon thyme, and sage in the neighbourhood of bee-hives. Those flowers which yield a nectar innocuous to the bees themselves, but possessing poisonous qualities when taken by man, are sometimes frequented by bees, and the honey derived from them acts like a poison. The description by Xenophon of the intoxicating or maddening honey, which so violently affected a number of the ten thousand Greek soldiers in his celebrated retreat, has been confirmed by the observations of Tournefort. And Dr. Barton, in his account of the poisonous honey collected from the Kalmia latifolia by the bees in Pennsylvania, justly observes, that there is more of poetry than philosophy in the following lines of Pope: —

> "In the nice bee what sense so subtly true,
> From poisonous herbs extracts the healing dew."

The honey which is swallowed by the bee passes into the crop, where it is accumulated as in a reservoir, and upon the return of the bee to the hive is regurgitated into a honey cell. If any honey had been previously accumulated there, the bee breaks through the firm cream-like crust which always forms upon the exposed surface of the honey; and it is this crust which maintains the honey in the horizontal cells.

The collection of the farina, or pollen, of flowers, is a great object of the industry of bees. In large flowers, as the tulip, the bee dives in; and if the pollen receptacle, or anther, be not burst, she bites it open, and comes out singularly disguised, being covered over entirely with the fertilising dust, which adheres readily to the fringed hairs of her body and legs.

Aristotle, who was well acquainted with much that is interesting in the economy of the bee, was the first to observe that a bee, during each single excursion from the hive, limits her visits to one species of flower. Modern naturalists have confirmed the general accuracy of this statement, and have noticed that the pollen with which a bee comes home laden is always of the same colour. The necessity of this instinct arises out of the operation which the pollen first undergoes when collected by the bee. She rakes it out with incredible quickness by means of the first pair of legs; then passes it to the middle pair, which transfer it to the hind legs, by which it is wrought up into little pellets. Now, if the pollen were taken indiscriminately from different flowers, it is probable that the grains, being heterogeneous, would not cohere so effectually. Certain it is, that bees enter the hive, some with yellow pellets, others with orange, pink, white, or even green coloured ones; but they are never observed to be party-coloured. Through this instinct, another important end is gained, in relation to the impregnation of flowers; the production of hybrid plants by the application of the pollen of one species to the stigma of another is avoided — while those flowers are more effectually fertilised, which require the aid of insects for that purpose.

When a pollen-laden bee arrives at the hive, she generally walks or stands upon the comb beating her wings, and three or four of her fellow citizens assist in lightening her of her load; or the laden bee puts her two hind legs into a cell, and with the intermediate pair, or the extremity of the abdomen, brushes off the pellets. These are then kneaded into a paste at the bottom of the cell; and several cells are thus filled with the packed and softened pollen, which is called bee-bread.

Besides the honey and farina, bees also collect a peculiar substance, like gum-resin, which was called 'propolis' by Pliny; and this they obtain principally from the balsamic buds of the horse-chestnut, birch, and poplar, especially the *Populus balsamifera*, L. The propolis is soft, red, will pull out in a thread, and is aromatic. It is employed in the hive, not only in finishing the combs, but also in stopping up every chink or orifice by which cold, wet, or any enemy can enter. Like the pellets of pollen, it is carried on the posterior tibiæ, but the masses are lenticular. Having thus traced the operations of the working bees relating to the collection of the substances required in the economy of the hive, we shall now return to the larvæ, which are the immediate objects of all this industry.

The bees may be readily detected feeding the young maggot, which opens its lateral jaws to receive the bee-bread, and swallows it. The well-fed maggot soon grows too large for its tough outer skin, and accordingly casts it; when its bulk has increased so that it fills its cell, it then requires no more food, and is ready to be inclosed for the chrysalis state. The last care of the foster-parents is to cover over the mouth of the cell with a substance of a light brown colour, apparently a mixture of wax and farina. This takes place generally four days after the larva was excluded from the egg. The inclosed larva now begins to line the cell, and covering of the aperture before mentioned, with a silk, which it spins from glandular tubes, similar to those of the silkworm. When the first three segments of the trunk, to which the locomotive organs of the perfect insect are attached, begin to be enlarged, the last larva-skin splits along the back, and is pushed off from the head backwards, and

deposited at the bottom of the cell, and it then becomes a chrysalis. Now the wonderful changes take place, partly by a formation of new organs, partly by a development of pre-existing ones, which end at last in the completion of the perfect bee.

Mr. Hunter ascertained the duration of the pupa state of the bee to be, in one instance, thirteen days and twelve hours, exactly; making the period of immature life, from the first deposition of the egg, to be twenty-two days and a half,—a remarkably brief time for the completion of the metamorphoses, as compared with that in which the corresponding changes are effected in other metabolian insects. When the bee first comes forth it is of a greyish colour, but soon assumes the ordinary brown tints.

When the season of oviposition and the rearing of the larvæ is over, then the business of collecting honey seriously begins; and when the last chrysalis of the season has disclosed its imago, the deserted cell is immediately filled with honey, and covered over with wax, to serve as a store for winter.

In the month of August it is supposed that the prolific female, which is to produce the swarms of the following year, is impregnated. This act takes place in the air. The queen, being preceded by the drones, traverses the exterior of the hive, and suddenly rises aloft in the air, wheeling upwards in large circles, until she is out of sight. The male, unable to extricate the intromitted parts, generally perishes. The rest of this unhappy sex share a similar fate, and meet a violent death from the jaws of the unprolific females. It would seem as if the drones were conscious of their danger at this season, for they do not loiter as usual at the mouth of the hive, but hurry in or out. However, they are attacked by one, two, or three workers at a time, who do not sting them, as Huber asserts, but pinch them and pull them about, as if to wear them out. From this instinctive and indiscriminate slaughter of the males, we may infer that the impregnation of the queen has taken place before the setting in of the winter season; and that the ova, the development of which is retarded during the indolent state in which bees pass through the cold months, are in a condition to be developed and produce the larvæ at the approach of spring. Yet, although on the setting in of the cold weather the bees remain very quiet, they are not torpid, as is the case with most other insects. They cluster as close together as the comb will permit, and have the faculty of generating a degree of heat superior to that of the external atmosphere.

Mr. Hunter found, during an evening in July, when the temperature of the atmosphere was 54°, that of the interior of a hive full of bees was 82°; and in December, the external atmosphere being 35°, the bees preserved a temperature of 73°; and, what is, at this season, extremely rare in the lower animals, they maintain their digestive powers, and subsist on the produce of the summer and autumn. Accordingly, they are ready to take advantage of any fine and mild day, and may be seen then flying abroad and appearing to enjoy it. They void their excrements at this time, for they are insects of singular cleanliness and propriety; and when purposely confined in the hive, with abundance of food, they have been known to fall a sacrifice to this instinctive repugnance to defile the hive.

The continuance of the digestive actions during the winter influences the condition of the oviducts in the queen, and the impregnated ova begin early to expand, and are ready for exclusion in the month of March. This makes the bee the earliest breeder amongst the insects of this country. The labourers now resume their accustomed duties, and, as the season is too early for collecting the provision of the maggot abroad, the store of bee-bread, laid up in the preceding year, comes into use, for the sustenance of the larvæ, which are about to form the first swarm. As soon, however, as the flowers begin to blow, the bees fly forth to gather fresh pollen, propolis, and honey, and the labours of the year recommence.

It appears to be the presence of the larvæ, which are destined to become perfect females, which stimulates the old queen to leave the hive. After repeated attempts to penetrate their cells, and destroy her royal progeny, she becomes infuriated, communicates her agitation to a portion of her subjects, which, together with her, rush out of the hive, and seek a new domicile. It is stated that in every instance the old queen leads the first swarm; the labourers that remain pay particular attention to the royal larvæ that remain; and these, as they are successively excluded, lead away fresh swarms, if the hive be not sufficiently enlarged. Each swarm contains, not only the recently hatched young bees, but also a portion of the old inhabitants. Some assert that the queen, which leads each swarm, is impregnated soon after the new colony is settled; and, as this may take place early in the summer, she begins to oviposit the same year. The number of ova which are fertilised by a single coupling is prodigious: Huber calculates that the queen lays 12,000 eggs in two months; while, according to Reaumur, she oviposits at the rate of 200 a day. The duration of life of the different individuals of the hive varies: that of the male bee is not more than two or three months; there is more doubt respecting the longevity of the workers, but it is probable that it does not extend much beyond a year. The term of the queen's existence has been stated to have been prolonged for five years; but this is rendered improbable by the fact that all insects of the same species have nearly the same duration of existence allotted to them.

The true honey-bee (*Apis mellifica* L.), was originally limited in its geographical range to the Old World, whence it has been transported to America, and other countries where European colonies have been established, and where it is now acclimated. The distinguished entomologist Latreille, on whose authority we state this fact (*Règne Animal*, tom. v. p. 365.), is even of opinion that the honey-bee of the south and east of Europe, as well as that of Egypt, differs specifically from the Apis mellifica of Western Europe.

API'STES. (Gr. *ἀπιστος, treacherous.*) A genus of Acanthopterygious fishes, notable for a strong suborbital spine, with which they are apt to inflict severe wounds when incautiously handled.

APLO'ME. (Gr. *ἁπλοος, simple.*) A mineralogical term for a variety of garnet crystallised in rhombic dodecahedra, derived by the simplest laws of decrement from the cube.

APLY'SIA. (Gr. *ἀπλυσια, uncleanness.*) A genus of Tectibranchiate Gastropods, well known to the ancients under the name of *Lepus marinus*, or sea hare, from a resemblance which the long tentacles of the Aplysia give it to the head of the hare. By Aristotle, the term Aplysia was applied to certain zoophytes, but was arbitrarily transferred by Linnæus to the molluscous animals now known under this denomination.

APO'CALYPSE. (Gr. *ἀποκαλυπτω, I reveal.*) The Book of Revelations, the last in the canon of the New Testament. Many conflicting opinions have been entertained as to the authenticity of this book; but, though rejected by Luther, and neither admitted nor rejected by Michaelis, the opinion of the great majority of critics and divines in modern times has been decidedly in favour of its genuineness. There have, also, been great varieties of opinion as to the person by whom, and the period when, the book was written: but the prevalent opinion is, that it is the work of St. John the Evangelist. Different commentators have differed widely in their interpretations of different parts of this book; and it is looked on by many as being still a "sealed book," admitting, in the present state of our knowledge, of no satisfactory explanation. The phrase apocalyptic writings is frequently used to designate those portions of the Scriptures which contain prophetic descriptions, under the form of visions, of the future state of the church: such as the book of Daniel; and, among the Apocrypha, the fourth book of Esdras.

APOCA'RPOUS. (Gr. *ἀπο, from,* and *καρπος, fruit.*) When the carpels of a flower either do not adhere to each other at all, as in the strawberry, or only by the ovaries, as in Aigella. When a carpel is altogether single in a flower, it is considered, for systematic purposes, apocarpous; the supposition being, that if another carpel were present, it would not adhere to the first.

APO'CRYPHA. (Gr. *ἀποκρυπτειν, to hide.*) Properly, things concealed or put out of sight; applied to certain books, in behalf of which a claim to inspiration has been put forth, but which are supposed to be spurious, and are therefore rejected from the canon of Scripture. One great distinction between the Roman and the Reformed churches is, that the latter reject certain books, admitted by the former on the same footing as those books about which there is no dispute, from the canon of the Old Testament; viz. the 3d and 4th of Esdras, the book of Tobias, that of Judith, the rest of the book of Esther, that of Wisdom, of Jesus the son of Sirach, Baruch the prophet, the Song of the Three Children, the story of Susanna, of Bel and the Dragon, the Prayer of Manasses, and the 1st and 2d Maccabees; reading them, as the sixth Article of the English church declares, for example of life and instruction of manners, but not applying them to establish any doctrine. The English church receives no books into the canon of the Old Testament which were not so received by the Jews; and it appears that the writings thus excluded are not quoted by the authors of the New Testament, nor are admitted into any of the earlier catalogues set forth by the Christian fathers. They are also found to contain some manifest inconsistencies, some obviously fanciful relations, and, in one or two passages, to countenance tenets at variance with the character, or even the express declarations, of revealed religion. There exist at the present day various writings purporting to be the Gospels or Epistles of Joseph, of James the Apostle, of St. Paul, an Epistle of Christ himself to king Abgamus, &c.; which are, for the most part, intrinsically absurd; and, having no external evidence or authority in their favour, have never obtained currency in the church. (*See* art. CANON.)

APOCYNA'CEÆ. An extensive natural order of plants, named after Apocynum, one of the more common of its genera. A few species are found in cold climates, but by far the larger part are natives of warm or tropical latitudes, in the form of shrubs or trees, or twining plants, some of which are remarkable for their beauty, as various species of Echites; others for their poisonous properties, as Cerbera, which furnishes the Tanghin poison of Madagascar, and Strychnos, from various species of which the poisons called tienté and woorary are procured in different countries; while a third set produce bark, having useful bitter and febrifugal properties; the inspissated milk that flows from these plants, when removed, constitutes their poison; the febrifugal bitter principle is an independent secretion, that becomes useful when it can be separated from the milk. Notwithstanding these dangerous properties, the fruits of some species are eatable, as that of Carissa, the cream fruit of Sierra Leone, and some others.

A'PODE. APODA. (Gr. ἀ, priv., and ποῦς, *a foot.*) Footless. A term applied by Latreille to a section of Saurians or lizards, by Mayer to a family of serpents, and by Oppel to a family of Batrachians; by Linnæus to his first order of fishes, which have no ventral fins; and by Cuvier a suborder of Malacopterygia, or soft-finned fishes, is thus designated, comprehending those which are devoid of the ventral fins, or the homologues of the posterior extremities. It is also indicative of those larvæ of insects which have only the soft tubercles or prolegs; and the skins of the bird of paradise, imported as an article of commerce, being always deprived of the legs, it was for some time believed that the species was naturally without feet, and it was consequently termed Paradisea apoda.

APODO'GYNOUS. (Gr. ἀ, priv., ποῦς, *a foot*, and γύνη, *a female.*) A name given by Richard to disks which do not adhere to the base of an ovary.

APO'DOSIS. (Gr. ἀποδιδωμι, *To give back.*) In Rhetoric, the second part of a period. (*See* PROTASIS.)

APODYTE'RIUM. (Gr. ἀποδυσθαι, *to strip one's self.*) In ancient Architecture, the apartment in the palæsta, or bath, in which a person divested himself of his dress, whether for bathing or for gymnastic exercises. In the baths of Nero, these apartments were small; but in those of Caracalla, the apodyterium was a magnificent room with columns and other decorations.

A'POGEE. (Gr. ἀπο, *from*, and γῆ, *the earth.*) Applied, in Astronomy, to the orbit of the moon and the apparent orbits of the sun or planets, to denote the points of those orbits most remote from the earth. It is opposed to perigee, which denotes the point nearest the earth. The apogee of the lunar orbit advances eastward among the stars, and completes a revolution in about nine years.

APOLLIN'ARIANS. In Ecclesiastical History, a sect who denied the humanity of Christ as far as regards the soul, believing its place to be supplied by the *Logos*, or Word of God. Apollinaris, their founder, was a bishop of Laodicea, in the latter part of the fourth century: his doctrine was condemned by the council of Constantinople, A. D. 381. (*See* Mosheim's Eccl. History, English translation, i. 423.)

APO'LLO, or PHŒBUS. A heathen divinity, son of Jupiter and Latona, in Homeric times the god of archery, prophecy, music, and medicine.

> Jupiter est genitor. Per me quod eritque, fuitque,
> Estque patet. Per me concordant carmina nervis,
> Certa quidem nostra, est nostra tamen una sagitta
> Certior in vacuo quæ vulnera pectore fecit;
> Inventum medicina meum est, opiferque per orbem
> Dicor, et herbarum est subjecta potentia nobis.

Later poets represent him also as the god of day and the sun. The statues of Apollo represent a young man in the perfection of manly strength and beauty, with unshorn curling locks, and a bow or lyre in his hand. The worship of this god was very general in Greece and Italy, especially in the former, where he uttered prophetic responses from many of his temples, the most celebrated of which were those of Delos and Delphi, in Phocis: in the latter of these his most esteemed oracles were delivered. The mythological tales about Apollo are very numerous. His birth took place in the island of Delos, whither his mother took refuge from the persecutions of the jealous Juno; and his first exploit was the slaughter of the dragon Python, for which, according to one tradition, he was subjected to servitude under Admetus, king of Pheræ, in Thessaly. Of his numerous amours, that with the nymph Daphne is most noted. She fled from his embraces, and, when no other means of escape from the arms of her pursuer were left, was turned by her father, the river-god Peneus, into a bay-tree, which in consequence became the peculiar emblem of Apollo.

APOLLO BELVIDERE. A beautiful statue of Apollo, found, towards the end of the fifteenth century, among the ruins of the ancient Antium. It was purchased by Pope Julius II., who placed it in the Belvidere of the Vatican, whence it takes its name. It is, perhaps, the noblest work of art. The god is standing, about seven feet high, and almost naked. His quiver hangs over his right shoulder; his pallium over his left arm, which is extended; and in his hand are the remains of a bow, out of which he is supposed to have just discharged the arrow that killed the serpent Python. The whole figure has about it an indescribable air of grace, beauty, and majesty.

> "Or view the Lord of the unerring bow,
> The God of life, and poesy, and light —
> The sun in human limbs array'd, and brow
> All radiant from his triumph in the fight;
> The shaft has just been shot — the arrow bright
> With an immortal's vengeance: in his eye
> And nostril beautiful disdain, and might,
> And majesty, flash their full lightnings by,
> Developing in that one glance the Deity."

This *chef-d'œuvre* of Greek sculpture has been supposed by some, but on very slight grounds, to be alluded to by Pliny (*Hist. Nat.* lib. xxxvi. § 4.). The best critics are of opinion that the artist is wholly unknown. This noble statue was conveyed to Paris by Napoleon; but, on the downfal of the latter, it was again restored to the Vatican.

A'POLOGUE. (Gr. ἀπόλογος.) In Literature, a fable or fiction, of which the object is moral. According to some definitions of the Apologue, it is a fable of which the interlocutors or subjects are animals: but this seems an unfounded limitation. (*See* FABLE.)

APO'LOGY. (Gr. ἀπολογία.) In Literature, a defence, or answer to an accusation. The two pieces of Xenophon and Plato, each commonly termed Apologia Socratis, differ in character: the first being a defence supposed to be pronounced by the philosopher himself; the last, a narration of his last hours and discourses. Treatises in defence of the Christian religion, in its early period, were denominated Apologies by their writers; as those of Justin Martyr, Tertullian, and others, both preserved and lost. The title has been retained by some writers in modern times: as by Robert Barclay, in his Apology of Quakerism, and by Bishop Watson, in his Apologies for the Bible and for Christianity.

A'POPHTHEGM. (Gr. ἀποφθεγμα, from φθεγγομαι, *I speak.*) A short and sententious speech or saying. The apophthegms of the ancients are generally sentences expressing some truth of universal application in philosophy, the conduct of life, &c. &c. Such are Plutarch's "Apophthegmata Laconica," a collection of the brief and pointed sayings for which the Lacedæmonians were famous.

A'POPHYGE. (Gr., signifying *flight*, or *refuge.*) In Architecture, that part of a column between the upper fillet which rests on the base and the cylindrical part of the shaft of a column, usually moulded into a hollow or cavetto, out of which the column seems as it were to fly or shoot upwards.

APOPHY'SIS. (Gr. ἀποφυω, *I proceed from.*) A protuberance, process, or projection. In Anatomy, restricted to processes of the osseous system.

A'POPLE'XY. (Gr. ἀποπλησσειν, *to strike down.*) A sudden suspension or loss of the powers of sense or motion; the heart continues to act, and respiration is continued, though often with some difficulty.

APOROBRA'NCHIANS, APOROBRANCHIATA. (Gr. ἀπορεω, *I want*, and βραγχια, *gills.*) A name applied by Latreille to an order of the class Arachnida, characterised by the absence of stigmata or respiratory pores on the surface of the body.

APOSE'PEDIN. (Gr. ἀπο, *from*, and σηπεδων, *product of putrefaction.*) A peculiar crystallised substance obtained from putrid cheese.

A'POSIOPE'SIS. (Gr. ἀποσιωπαω, *To leave off speaking suddenly.*) A figure in Rhetoric and Composition, by which a sentence is made to break off abruptly when unfinished either in sense or grammatical construction; so that the part which was to follow appears to be retained in the mind of the speaker or writer. In writing, the Aposiopesis is now often denoted by an horizontal line or break at the point where the sense is interrupted.

APO'STACY. (Gr. ἀφίστημι, *I desert.*) A deserting or abandoning of the true faith; but the word is now used to designate the renunciation of political as well as religious opinions.

APOSTASIA'CEÆ. A very small natural order of plants found in the tropics of India, closely allied to Orchidaceæ, from which they differ in having a three-celled ovary and diandrous flowers, the sexes of which are partly free. Apostasia is the principal genus.

APO'STILL. In Literature, a marginal note to a book.

APO'STLE. (Gr. ἀποστολος.) A person sent forth upon any business: hence applied, by way of eminence, to the twelve elect disciples of Christ, who were sent forth by him to convert and baptize all nations. In the first century, the apostles assumed the highest office in the church; and the term apostle during that period was equivalent to bishop in after times. According to Theodoret (v. Bingham, II. Q. 1.), the titles of bishop and

presbyter were originally applied promiscuously to the same, or second, order in the church.

APO'STLES' CREED. A confession of faith, supposed anciently to have been drawn up by the apostles themselves, and deriving the title "Creed" from the word with which it begins in Latin (credo, *I believe*). With respect to its antiquity, it may be affirmed, that the greater part of its clauses is quoted by the apostolic father Ignatius; and that the whole, as it now stands in our liturgy, is to be found in the works of St. Ambrose, in the fourth century.

APOSTO'LIC FATHERS. The writers of the Christian Church, who lived in the apostolic age, or were during any part of their lives contemporary with the apostles. They are five: Clement of Rome, Barnabas, Hermas, Ignatius, and Polycarp; of whom the last suffered martyrdom, A. D. 147. Of these the three first are supposed to be mentioned in the Epistles and Acts; the fourth, according to a prevalent tradition, was the child whom Christ took in his arms, whence he was called Theophorus; and the fifth, who suffered at a very advanced age, seems to be the angel or bishop of Smyrna whom St. John addresses in the Revelations.

APO'STROPHE. (Gr. ἀποστρέφειν, *to turn off.*) In Rhetoric, a figure of speech by which the orator or writer suddenly breaks off from the previous method of his discourse, and addresses himself in the second person to some person or thing, absent or present. It is not necessarily an address to the absent or dead, although often so defined. An orator, who should suddenly direct his speech to one of the audience, would be employing an apostrophe. It is, like other figures of speech, an imitation of one of the most natural effects of strong emotion. In oratory, the Apostrophe of Demosthenes to the gods, at the end of the *Oratio pro Coronâ* in narrative writing, that of Tacitus to the shade of Agricola, in his biography of that statesman, may be cited as splendid examples in ancient literature of the use of this figure.

APOTHE'CA. (Gr. ἀποθήκη, *a repository.*) In ancient Architecture, a storehouse for oil, wine, &c.

APO'THECARY. (Gr. ἀποθήκη, *a shop.*) Apothecaries were originally the venders and preparers of drugs and compounds used in medicine. The Apothecaries' Company, or the Society of Apothecaries for the City of London, was incorporated by James I. in 1606. Their last charter bears date 6th of December, 1617. (*See* COMPANIES.)

APOTHE'CIUM. (*See* APOTHECA.) A flat disk, consisting of a nucleus surrounded by a border, in which the asci of lichens are inclosed. It is commonly called a shield.

A'POTHEO'SIS. (Gr. ἀποθέωσις.) The change from a mortal to a divine nature, which the ancients supposed some men to undergo after death: as the old heroes among the Greeks; and the ancient kings of Italy, and Romulus, with the Romans, who also paid divine honours, in later times, to their deceased, and, in some cases, to their living, emperors.

AP'OTOME. (Gr. ἀποτομος, *cut off.*) In Music, the remaining part of an entire tone, after a major semitone has been abstracted from it; or it is the remainder of a whole tone when diminished by a limma, or smaller semitone. As the tone major cannot be rationally divided into two equal parts, the Greeks divided it into a greater and less semitone; the greater being the apotome, and the less the limma. The proportion of the apotome to the limma is 2187 to 2048.

APOTOME. In Geometry, a term employed by Euclid and some of the ancient mathematicians to denote the remainder or difference between two lines or quantities commensurable only in power. Thus, if from the diagonal of a square, a part equal to the side of the square is cut off, the remainder is the apotome, and is represented numerically by the expression $\sqrt{2}-1$. In the tenth book of his Elements, Euclid divides apotomes into six classes.

A'POZEM. (Gr. ἀπο, and ζειν, *to boil.*) An old Pharmaceutical term for a decoction.

APPA'RENT. A term used in Astronomy to denote things as they appear to the eye, in distinction to what they really are. Thus, the apparent altitude of a star denotes the angle which its line of vision makes with the horizon; but the real altitude is found by making a correction for the effects of parallax, which causes the star to appear a little higher than it would if there were no atmosphere. The apparent diameter of a planet is measured by the angle made by two straight lines drawn from the eye to opposite points of its disk; the real diameter is a straight line joining those points; while astronomers call the angle under which the diameter would be seen from the centre of the earth, the true diameter. The apparent or sensible horizon denotes the plane which is a tangent to the earth's surface at the place of the observer; the true horizon is a plane parallel to the former, and passing through the centre of the earth. Apparent motion is the velocity and direction in which a body appears to move to an observer who is himself in motion. For example: the apparent diurnal motion of the stars from east to west arises from the rotatory motion of the earth, which carries us along with it in an opposite direction. Apparent time is the same as true time, or the hour indicated by the sun's passage over a meridian; while mean time is that which would be indicated by the sun if its angular velocity in its orbit were uniform.

APPARI'TION. In a general sense, means the appearance or semblance of any thing; but the word is now commonly used to denote a spectre, or the preternatural appearance of some spirit. A belief in the reality of such preternatural appearances has been entertained by many eminent men; but it has chiefly prevailed in times of ignorance and superstition, and has either wholly disappeared, or had a comparatively limited influence in more enlightened times.

APPEA'L. In Law, 1. The removal of a cause from an inferior court to a superior. 2. An accusation of a criminal offence by one subject against another. The bringing decisions of the courts of Scotland and Ireland, or the court of chancery in England, before the house of lords, is peculiarly termed an appeal in the first sense. Criminal appeals are now obsolete: those on charges not capital have long been so. Appeals of treason and of felony subsisted for a much longer period: the latter had doubtless their origin in the early jurisprudence of the Gothic nations, by which acts of violence or injury were redeemable by a weregild or fine to the party injured or his near estrelative. They were put an end to by stat. 59 G. 3. c. 46. (*See* WAGER OF BATTLE.)

APPEA'RANCE. In Law, the act whereby a defendant in an action recognises the process by which that action is commenced against him: originally by appearing in person, or by attorney, in court; now, by filing common or special bail to a writ of capias, by delivering a memorandum in writing to an officer of the court, in answer to a writ of summons, &c.

APPE'LLANT. In Law, the party by whom an appeal is made; as against an order of magistrates to the quarter sessions, or against the decision of a court of equity to the house of lords. The opposite party is termed respondent.

APPE'NDAGE. In Botany, all parts which are regularly arranged round any other part are called appendages; leaves are appendages of the axis: so are all the parts of a flower theoretically; the supernumerary sepals in a strawberry are appendages of the calyx; the abortive stamens that arise from the calyx of a passion-flower are appendages of the calyx; and so on.

APPEND'ICULATE. Having appendages. The word is sometimes applied to all those plants which are furnished with leaves (appendages of the axis).

APPE'NDIX. In Literature, a supplement added at the end of a work, either to contain portions of the subject which had been omitted, or separate pieces and extracts from other works bearing on it: such as are termed in French *pièces justificatives.*

APPE'NSUS. (Lat. appendo, *I hang up.*) When an ovule is not exactly pendulous, but is attached to the placenta by some point intermediate between the apex and the middle.

A'PPIAN WAY. The most celebrated of the highways leading from ancient Rome. It was constructed by the censor Appius Claudius, A. U. C. 442; and commencing at the gate of Capena, now St. Sebastian, extended to Capua, the then limit of the empire. It was formed of stones squared and jointed, and was wide enough for two chariots to go abreast. On each side was a ditch for carrying off the water.

A'PPLE. (Gr. ἀπιος, *a wild pear.*) The cultivated fruit of *Pyrus malus*, the crab apple of our hedges. All the numerous varieties that are now so common are said to have originated slowly from improvements of this wild sort. At what period its amelioration commenced is unknown; but, as Pliny was acquainted with several kinds, it is reasonably to be supposed that its improvement is to be assigned to a high antiquity. If it could be true that pippins, that is, seedling improved apples, were introduced only at the end of the 16th century, we should have to give the southern nations of Europe the credit of having furnished us with the stock from which the valuable varieties we now possess have been derived. But there is no doubt that apples of some kind have been known in England from long before the Conquest, and although they may have been of bad quality, and fit for food only when roasted, yet they could hardly have failed to produce seedlings of valuable qualities. The term apple is employed in composition to designate any large fleshy fruit, as love-apple, thorn-apple, pine-apple, &c.

APPOGIATU'RA. (Ital. appogiare, *to lean upon.*) In Music, a small note preceding a larger one of greater duration, of which it borrows one half of its value: sometimes, however, it is only one quarter in duration of the note which it precedes.

APPO'RTIONMENT. In Law, the dividing of a rent, &c. into parts, according to the number and proportion of the parties between whom the land is divided.

APPRAI'SEMENT. The valuation of goods sold under distress for rent due, by sworn appraisers, under several statutes. (*See* DISTRESS.)

APPREHE'NSION, SIMPLE. In Logic, is that act or condition of the mind in which it receives a notion of any object, and is said to be either incomplex or complex: the former being the apprehension of one object, or of several without any relation between them, as "a man," "cattle;" complex, of several, with such a relation, as "a man on horseback," "a herd of cattle."

APPRE'NTICE. (Fr. apprendre, *to learn.*) A person bound by indenture, for a certain term, to perform services for a master, receiving, in return, instruction in a trade or occupation; and, in most instances, necessary food and clothing. Apprenticeship seems to have originated, together with guilds and fraternities, in the middle ages. Seven years is a common term of apprenticeship in Germany, as well as in England; but other periods, as three and eight, have been customary in different trades, places, and times. The former period was fixed in England by the statute 5 Eliz. c. 4., which regulated apprenticeship throughout the realm in general. By 54 G. 3. c. 96., the legal force of apprenticeship was finally destroyed; that is, persons were allowed to exercise their respective trades without having served; London, and a few other corporate towns, being excepted. Apprenticeship is, therefore, now only recognised by the law as the mode of learning a trade.

APPROA'CH. In Fortification, a term given to the trench or covered way by which a besieging army may advance from its camp to the wall of a fortress without being exposed to the fire of the defenders. Approaches sometimes consist of covering masses only, formed of earth in bags, fascines, stuffed gabions, woolpacks, bales of cotton, or other materials within reach.

APPROACH, CURVE OF. In Geometry, the name given to a curve which possesses this property, — that a heavy body descending along it by the force of gravity, makes equal approaches to the horizon in equal portions of time. It was proposed by Leibnitz, and its propertles investigated by Bernoulli and others.

APPROACH ROAD. In Landscape Gardening, is the road which leads from the public or main road, through a park or pleasure ground, to the mansion of a country residence. In the ancient or geometric style of gardening, this road was bounded by lines either straight or regularly curved, and was generally accompanied by one or more rows of trees on each side, at regular distances: but in the modern style, the approach road is led in graceful sweeps, which are made to appear as if they were determined by existing circumstances, either in the surface of the ground, or in the trees or other objects which are placed on it. There ought to be no bend in an approach road for which there is not an obvious and sufficient reason, either naturally existing, or created by art.

APPRO'PRIATION. In Landscape Gardening, is the art of so blending the scenery of one estate with that of the others that adjoin it, as to make the one subservient to the other, in a scenic point of view. This is effected by forming appropriate fore-grounds, in the estate at command, to the distant views, in the estates not at command; or in fields immediately adjoining, by imitating in our own field a part of what is contained in the field of our neighbour: thus, if the park of A. should be chiefly planted with pines and firs, and that of B. chiefly with oaks; A., in order to appropriate the scenery of B., must substitute oaks for a part of his pines and firs; more especially in the immediate vicinity of the grounds of B.

APPRO'VER. In Law, a person who being indicted of treason or felony, and not disabled from giving legal evidence, upon his arraignment, before any plea pleaded, confesses the indictment, and takes an oath to reveal all treasons and felonies that he knows of, and therefore prays a coroner to enter his appeal or accusation against those that are his partners in the crime contained in the indictment.

APPRO'XIMATE. In Zoology, when the teeth are so arranged in the jaws, that one passes on the side of the next, and there is no intervening vacancy.

APPROXIMA'TION. (Lat. proximus, *nearest, next to.*) A drawing near to. In Mathematics, quantities are said to be approximate which are nearly but not absolutely equal.

In a general sense, the term approximate may be applied to every result of natural philosophy or experimental science. For example, the magnitude of the earth, the distance of the sun, the masses of the planets, in fact, all the elements of astronomy, are only known nearly, or by approximation. In these cases, however, the want of absolute knowledge arises from the imperfections of our senses, or the errors of our instruments. In the language of Analysis, approximation is used to denote those methods of calculation by which we obtain near values of quantities which cannot be found accurately, either on account of the nature of their composition, or the imperfections of our methods of calculation.

The problem of finding the length of the circumference of a circle, by means of inscribed polygons, affords an instance of approximation to the values of geometrical quantities. It is a principle in Geometry, that any arc of a circle, however small, is greater than its chord. Now, suppose a regular polygon of 100 sides to be inscribed in a circle, and that we know the exact length of one of the sides; it is evident that the sum of all these lengths will give an approximation to the length of the circumference, though it would fall short of it by a very sensible quantity. But suppose that, instead of a polygon of 100 sides, one of 1000 sides were inscribed in the circle, the aggregate lengths of the sides would now approach much more nearly to the length of the circumference. By continuing to multiply the number of sides, we may obtain an approximation to any degree of nearness we please; but whatever the number of the sides of the polygon may be, their sum will never be exactly equal to the circumference, for they are only the chords of small arcs, which of necessity are smaller than the arcs to which they belong.

Numbers are formed by successive additions of unity, which is necessarily a finite quantity. In consequence of this finitude, it may be affirmed that no magnitudes which flow, or increase, by insensible degrees, can be expressed generally by numbers. For example, let a straight line be taken at random, and suppose that we wish to determine its length, our unit of linear measure being one foot. On applying successively a scale divided into feet to the different parts of the given line, the chances are infinity to one that the last division does not exactly coincide with the extremity of the line. We may diminish our unit by reducing it to an inch, or to the hundredth or the thousandth part of an inch; the chances of ultimate coincidence will not thereby be increased, though the difference between the last division of the scale and the extremity of the line may be diminished till it becomes smaller than any quantity we may be pleased to assign. Precisely similar to this is what takes place when we attempt to express by decimals a vulgar fraction whose denominator is not a measure of any power of ten. Thus, the fraction $\frac{1}{3}$, expressed decimally, is ·33333, &c. The first figure of the series gives the approximate value 3-tenths; the first two figures give 33-hundredths; the first three, 333-thousandths, and so on; the addition of every figure to the series making the difference of its value from 1-third ten times smaller. The difference may, therefore, be diminished till it becomes smaller than any assignable quantity, but it can never entirely disappear.

Another instance of the necessity of having recourse to approximation, is presented in seeking to find the roots of numbers. If a number is not an exact square, its square root cannot be expounded by rational numbers, whether integers or fractions. The same thing occurs with respect to numbers which are not cubes, and so on. In these cases, exact numerical values of the roots cannot be found. In other cases exact values may exist, though our methods of analysis are not sufficiently perfect to enable us to discover them. Notwithstanding the successive efforts of the greatest algebraists since the days of Lucas de Borgo, no general method has yet been discovered of solving equations of a higher degree than the fourth; consequently, the values of quantities involved in such equations can only be obtained approximately. It is to this subject that the attention of our best writers on analysis has chiefly been directed; in fact, the discussion of the different methods of approximating to the roots of equations of the higher degrees, forms one of the principal subjects of pure Algebra.

The method of exhaustion, by which the ancient mathematicians attempted to find the rectification and quadrature of the circle, was the first instance of a systematic method of approximation. The Indivisibles of Cavalleri effected the same object in a more rapid and general manner, and prepared the way for the differential calculus. The invention of the method of infinite series led immediately to general methods of approximating to the values of all radical quantities, and subsequently to the roots of all kinds of compound equations whatever. Vieta was the first who showed how to find successive values of the roots of equations, each approaching more nearly to the true value than the preceding; but his method was tedious and imperfect. Other methods, more easy and general, have been given by various mathematicians; among which, the best known are those of Newton, Halley, and Raphson, and those which have been proposed at a later period by Lagrange, Legendre, Budan, and others. These methods are in general drawn from the most abstruse parts of the theory of equations, and could not be explained in this place with the details necessary to render them of any use. For the best information on the subject, we may refer the reader to the excellent work of Lagrange, "Traité de la Résolution des Equations Numériques;" the "Nouvelle Méthode pour résoudre les Equations Numériques" of M. Budan; the "Supplément à l'Essai sur la Théorie des Nombres," by

Legendre; and the article *Equations*, in the Encyclopedia Britannica, by Mr. Ivory. (*See* Equations.)

A'PRICOT. (Lat. præcox, *early*, or Arab. berkhach, *butter fruit.*) The fruit of Armeniaca vulgaris, a native of Cachmere, and probably of the mountains of Caubul, and cultivated from Persia and the Oases of Egypt throughout the temperate parts of the world. In its wild state the apricot is a small round pale waxy yellow fruit, rosy on one side, and agreeably subacid; in that state it is dried in large quantities under the name of mishmish; in its most improved state it becomes three times as large and sweeter: but it is then apt to become insipid. For the confectioner's purpose, the Brussels and Breda apricots, which are near approaches to the wild fruit, are better adapted than the larger and sweeter kinds.

A'PRIL. The fourth month of the year. The name is probably derived from Lat. aperire, *to open*, either from the opening of the buds, or of the bosom of the earth, in producing vegetation.

A PRIO'RI. (The argument *à priori.*) In Philosophy and Rhetoric, is a phrase somewhat loosely applied to designate a class of reasonings. It is generally understood to apply to any argument in which a consequent conclusion is drawn from an antecedent fact, whether the consequence be in the order of time, or in the necessary relation of cause and effect; — e. g., "The mercury sinks, therefore it will rain." This is an argument drawn from an antecedent in time, not from a cause to an effect. A murder has been committed; a party falls under suspicion, as having had an interest in the death of the deceased, or a quarrel with him: this suspicion is founded on the argument *à priori*, from cause to effect; because the fact of his enmity or interest would afford a cause for his committing the murder. On the other hand, another party falls under suspicion, as having been seen to quit the house at a particular time, having marks of blood on his clothes: these are arguments *à posteriori*, in which we reason either from consequent in the order of time to antecedent, or from effect to antecedent cause. The famous *à priori* argument of Clarke and others in favour of the existence of a God, was an argument drawn from certain primary axioms in metaphysics; while the common course of reasoning to prove the same truth from the visible proofs of design in the works of nature, is an instance of the latter or *à posteriori* form.

A'PSIDES, or APSES. (Gr. ἁψις, *circle*, or *curvature.*) The two points of the orbit of a planet or satellite, at which it is moving at right angles to the straight line joining it with the primary. These two points of the orbit are the two extremities of the major axis, or the points at which a planet is at its greatest and least distance from the sun. The point at the greatest distance is called the higher apsis; that at the least is called the lower apsis; consequently, the higher apsis corresponds with the aphelion, and the lower apsis with the perihelion. The line joining these two points, which is the transverse axis of the orbit, is called the line of the apsides. It has a slow angular motion in the plane of the planet's orbit; and the time which the planet employs in completing a revolution with regard to its apsides is called the anomalistic period. (*See* Aphelion. Anomaly.)

APTENODY'TES. (Gr. ἀ, priv., πτηνος, *that can fly.*) A genus of diving web-footed birds, peculiar to the antarctic shores, having wings too short for flight, covered with short stiff feathers, resembling scales, and used as fins or paddles for swimming under water. The legs are short, thick, set far back, with four toes, all turned forwards, three of them long and webbed, the fourth very short. The bill is longer than the head, straight, and slightly curved at the tip: nostrils in the upper part of the bill, concealed in front by feathers. The Patagonian penguin is the representative of the genus.

A'PTERANS. APTERA. (Gr. ἀ, priv., πτερον, *a wing; wingless.*) A term including a proportion of the class of insects, the value of which varies in different systems of Entomology. In the Linnæan system it is the seventh order of insects, distinguished by their having no wings. Kirby makes his Aptera the twelfth order of the class of insects, but acknowledges that it is not a natural one, and limits the definition of it to those insects which are apterous, or never acquire organs of flight. In Latreille's last system, aptera is no longer applied to designate an order of insects.

A'PTEROUS. In Botany, denotes any part of a plant which is destitute of membranous expansions. The term is usually employed in distinction to alate, or winged.

A'PTERYX. (Gr. ἀ, priv., πτερυξ, *a wing.*) A genus of birds represented by an extremely rare species, a native of New Zealand, in which the wings are reduced to a single defensive spur.

A'PTHOUS. (Gr. ἅπτειν, *to inflame.*) Resembling Aphtha or Aptha, the disease called the *thrush*.

A'PUS. A name applied by Scopolo to a curious genus of Entomostracans; characterised by a flattened, semitransparent, membranous envelope, which protects the body like a shell, having a deep cleft posteriorly; and bearing in front two large eyes, placed close together, with a third smaller one behind. The first pair of legs are long, filamentary, and branched, representing antennæ; the remaining sixty pairs are short, compressed, and modified so as to form a respiratory organ; according to the structure which characterises the Branchiopodous, or gill-footed order, to which the Apus belongs. The species of Apus appear in immense numbers in our freshwater pools; they prey chiefly on tadpoles; and some attain the length of an inch and a half.

APYRE'XIA. (Gr. ἀ, priv., and πυρετος, *fever.*) The intermission of feverish disorders.

A'PYROUS. (Gr. ἀ, priv., and πυρ, *fire.*) A term formerly applied to substances which resisted a strong heat without change.

A'QUA. (A Latin word of uncertain derivation, but probably from æqua, *smooth*, or *level.*) Water. It is often almost Anglicised, as in the words aquavitæ, aquafortis, aquamarine.

AQUA FORTIS. Nitric acid.

A'QUAMARI'NE. See Beryl.

AQUA REGIA. A mixture of nitric and muriatic acids, so called from its power of dissolving gold, the king of the metals.

AQUA TOFFANA. See Aquetta.

AQUA'RIUM. (Lat. aqua, *water.*) In Horticulture. A place in gardens, in which only aquatic plants are grown. It is generally a small pond or cistern, containing shelves or benches at different depths from the surface, in which pots are placed containing the plants.

AQUA'RIUS. *The Waterbearer.* The eleventh sign of the zodiac, through which the sun moves in part of the months of January and February. Also, one of the twelve zodiacal constellations.

AQUA'TICS. AQUATILIA. (Lat. aquaticus.) A name applied by Nitzch to an order of birds; by Cuvier, to a family of Mollusks; by Latreille, to a division of Crustacea: by Lamarck to a family of bugs (*Cimicidæ*); each of which groups includes animals which live in, swim on, or frequent the margins of waters.

AQUA'TIC PLANTS. Plants which grow in water, which may be either running or stagnate. In the former case they are called river plants; in the latter, pond plants. Such as grow in the sea are called marine plants.

A'QUATINT. (Lat. aqua, *water*, tinta, *dyed.*) In Engraving, a species of execution resembling an Indian ink drawing in effect. (*See* Engraving.)

A'QUEDUCT. (Lat. aqua, *water*, and ductus, a *conduit.*) A conduit or channel for conveying water from one place to another; more particularly applied to structures erected for the purpose of conveying the water of distant springs across valleys, for the supply of large cities.

The largest and most magnificent aqueducts, with the existence of which we are acquainted, were the work of the Romans; and the ruins of several of them, both in Italy and other countries of Europe, remain to the present time monuments of the power and industry of that enterprising people. The aqueduct of Appius Claudius was the most ancient, and constructed in the 442d year of Rome. It conveyed the Aqua Appia to the city, from a distance of between 7 and 8 miles, by a deep subterranean channel of more than 11 miles in length. The aqueduct of Quintus Martius was a more extraordinary structure. It commenced at a spring 33 miles distant from Rome, made a circuit of three miles, and afterwards, forming a vault of 16 feet diameter, it ran 38 miles, along a series of arcades at an elevation of 70 English feet. It was formed of three distinct channels, placed one above the other, conveying water from three different sources. In the uppermost flowed the Aqua Julia; in the second, the Aqua Tepula; and in the undermost, the Aqua Martia. The Aqua Virginia, constructed by Agrippa, passed through a tunnel of 800 paces in length. The Aqua Claudia, begun by Nero and finished by Claudius, conveyed the water from a distance of 38 miles. This aqueduct formed a subterraneous stream of 30 miles in length, and was supported on arcades through the extent of 7 miles; and such was the solidity of its construction that it continues to supply the modern city with water to the present day. The waters of the river Anio were also conducted to Rome by two different channels; the first was carried through an extent of 43 miles, and the latter through upwards of 63 miles, of which $6\frac{1}{2}$ miles formed one continued series of arches, many of them upwards of 100 feet in height. Nine great aqueducts existed at Rome at the commencement of the reign of Nerva. Five others were constructed by that emperor, under the superintendence of Julius Frontinus; and it appears that at a later period the number amounted to twenty. The supply of water furnished by these different works was enormous. "According to the enumeration of Frontinus, the nine earlier aqueducts delivered every day 14,018 quinaria. This corresponds to 27,743,100 cubic feet. We may therefore extend the supply, when all the aqueducts were in action, to the enormous quantity of 50,000,000 cubic feet of water. Reckoning the po-

pulation of ancient Rome at a million, which it probably never exceeded, this would furnish no less than 50 cubic feet for the daily consumption of each inhabitant."—(*Leslie's Elements of Natural Philosophy.*)

The remains of some Roman aqueducts in other parts of Europe give evidence of the existence of works on a still more magnificent scale than those of Rome. Of these the aqueduct of Metz was one of the most remarkable. A number of its arcades still remain. It extended across the Moselle, a river of very considerable breadth at this place, and conveyed the water of the Gorse to the city of Metz. The water was received in a reservoir, whence it was conducted by subterraneous canals, formed of hewn stone, and so spacious that a man might walk in them upright. The arches appear to have been 50 in number, and 50 feet high at the deepest part. Some of the middle ones have been swept away by the descent of ice down the river; those at the extremities still remain entire.

The aqueduct of Segovia, in Spain, is in a still more perfect state than that of Metz. About 150 of its arcades remain, all formed of large stones without cement. There are two rows of arcades, the one above the other, and the height of the edifice is about 100 feet, passing over the greater part of the houses of the city.

Aqueducts have been constructed in modern times, particularly in France, which rival those of the ancient Romans. One of the most remarkable was constructed by Louis XIV., for conveying the waters of the river Eura to Versailles. It extends about 4400 feet in length, or nearly seven eighths of a mile, and is upwards of 200 feet in height. It contains 242 arcades, each divided into three rows, forming in all 726 arches of 50 feet span. The introduction of cast-iron pipes, which has only taken place within the last century, has superseded the use of such expensive structures.

A'QUEOUS SOIL. Agr. and Hort. Soil naturally abounding in water, the fluid being supplied by springs in the subsoil.

AQUE'TTA. (Ital. *little water.*) A celebrated poison used by the Romans under the pontificate of Alexander VII. It was probably a preparation of arsenic, and was also known under the name of *aqua Toffana*, from a woman of the name of Toffana, who prepared it at Naples.

AQUIFOLI'ACEÆ. (Lat. Aquifolium, *the holly.*) A natural order of Exogens, connecting the monopetalous with the polypetalous subclasses. The whole of the species are either shrubs or trees, and scattered over most parts of the world. Ilex, Prinos, and Cassia are the commonest genera.

A'QUILA. (Lat. aquila, *an eagle.*) The genus of Accipitrine or Raptorial birds, including the eagles proper, or those species of the Linnæan *Falco*, which have no trenchant tooth and corresponding notch in the beak.

A'QUILA ALBA. (Lat. *the white eagle.*) An alchemical name of *calomel*. The old chemists designated sal ammoniac and other sublimates by the term aquila.

AQUILARIA'CEÆ. (Aquilaria, *eagle wood, one of the genera.*) A very small order of Indian plants, secreting a fragrant resin, and nearly allied to Thymelaceæ. The species are but little known. The Aquillaria agallochum is the tree that produces the eagle or aggul wood, and which, in all probability, was the aloes wood of Scripture.

ARABE'SQUE. (French.) Painting and Sculpture, after the Arabian taste. This is a term applied to a species of ornament, capricious, fantastic, and imaginary, consisting of fruits, flowers, and other objects, to the exclusion, in pure Arabesques, of the figures of animals, which religion forbade. That the Arabians originated this sort of ornament is not the fact; it was known to and practised by the ancients at a very early period. Foliage and griffins, with ornaments not very dissimilar to those of the Arabians, were by no means unfrequent in the friezes of temples; and on many of the ancient Greek vases at Herculaneum, on the walls at the baths of Titus, at Pompeii, and many other places, elegant examples of this species of decoration are to be found. It is, however, to Raphael that we owe the most splendid specimens of the style, which he dignified, and left in it nothing to be desired. Since his time it has been practised with varying and inferior degrees of merit, especially by the French in the time of Louis XIV. Arabesques lose their character when applied to large objects, neither are they appropriate where gravity of style is required.

A'RABLE. (Lat. arare, *to plough.*) Land fit to be brought into a state of tillage, or of aration.

A'RABO-TEDE'SCO. (Ital. arabo, and tedescho, German.) In Painting and Sculpture, a style of art composed of Moorish, Roman, and German-Gothic.

ARA'CEÆ, or AROIDEÆ. (*Arum, one of the genera.*) Acrid Endogens, with the flowers arranged upon a spadix, inclosed within a spathe. In hot countries they sometimes become arborescent; in many cold countries they are unknown. Most commonly they arise from a fleshy underground tuber, from which an eatable fæcula is procured by washing away the acrid matter. Their flowers are almost destitute of floral envelopes; the sexes are mostly placed in different flowers, and their embryo has a slit on one side. *Caladium seguinum*, the dumb cane of the West Indies, derives its name from its juice paralysing the muscles of the mouth, if chewed; nevertheless, the leaves of certain caladiums are eaten by the negroes like spinach, but they are too acrid for an European palate.

ARA'CHNOID. (Gr. ἀραχνη, *a spider*, and ειδος, *form.*) Cobweb-like. It is an Anatomical term, applied to the tunic of the vitreous humour of the eye, and to the thin membrane placed between the dura and pia mater of the brain.

ARACHNI'DANS. ARACHNIDA. (Gr. ἀραχνη, *a spider.*) A class of Apterous, spider-like Condylopes, having the head confluent with the chest, and, the body, consequently, consisting of but two segments, with eight legs, smooth eyes, and the sexual orifices situated on the thorax, or anterior part of the abdomen.

ARÆO'STYLOS. (Gr. ἀραιος, *wide*, and στυλος, *a column.*) In Architecture, that style of building in which the distance between the columns used is four and sometimes five diameters; the former, however, is the distance to which the term is strictly applied. It is only suited to the Tuscan order.

AR'ÆOSY'STYLOS. (Gr. ἀραιος, *wide*, συν, *with*, and στυλος, *a column.*) In Architecture, that style of building in which four columns are placed in a space equal to eight diameters and a half. In this arrangement the central intercolumniation is equal to three diameters and a half, and the others on each side only half a diameter, by which coupled columns are introduced.

ARALIA'CEÆ. (Aralia, *one of the genera.*) An order of Exogens, differing in little from the Apiaceous or umbelliferous plants, except in having more than two parts in their fruit. They are commoner in hot than in cold latitudes, and form an unexpected transition from Apiaceæ to Vitaceæ. The only state of them in Europe is the diminutive Adoxa moschatellina.

ARANEI'DANS. ARANE'IDÆ. (Lat. aranea, *a spider.*) A tribe of the Pulmonary order of Arachnidans, with a coriaceous integument; modified antennæ, or chelicers, consisting of a single joint armed with a claw, perforated near the apex for the transmission of venom; breathing by pulmonary ones, which are either two or four in number, with the abdomen pedicellate, and the arms provided with four or six spinnarets.

ARANEO'SUS. (Lat. aranea, *a spider.*) Covered with hairs crossing each other like the rays in a spider's web.

A'RAR. The Barbary name of *Thuja articulata*, the tree whose wood is chiefly used by the Mahometans of Africa for the construction of their mosques, and whose resin is the sandarach of commerce.

ARA'TION. Agr. Lands are said to be in a state of aration, when they are under tillage.

ARA'TOR. Agr. Literally a ploughman, but commonly applied to an arable farmer.

ARAUCA'RIA. (Araucanos, *a tribe of Indians in the southern parts of Chili.*) Fir trees with very rigid branches, having leaves like scales, either small and sharp pointed, or stiff, spreading, and lanceolate. The cones consist of leaves something like those of the stem, only longer, and containing large seeds. Two species occur in South America, and two in New Holland.

A'RBALEST. (Lat. arcubalista, *a cross-bow.*) This weapon is supposed to have been introduced into European armies by the crusaders, although used long before in the chase (in England as early as the reign of William the Conqueror). The arrows used with the cross-bow were short and thick (quarrels, bolts). The weapon was used in the English armies after the reign of Richard I.; but the Italians, and especially the Genoese, were most expert in the use of it at one time. A large force of Genoese cross-bow men served in the French army at Cressy, where their weapon was found very inadequate to match the English long-bow. Yet so deadly a weapon was it at one time considered, that papal bulls were issued in the twelfth century, condemning and forbidding its use in combats between Christians. It was disused in England, as a weapon of war, in the reign of Henry VIII. Cross-bows were of several sizes: the large or stirrup cross-bow was bent by the foot.

A'RBITRARY. (Lat. arbitro, *I judge.*) In a general sense, means that which is not defined by any rule or law, but is left to the sole judgment and discretion of some one individual or body of individuals. It is commonly used in political discussions to designate despotical or irresponsible power. (*See* DESPOTISM.)

ARBITRA'TION. In Law, the investigation before an unofficial person of the matters in difference between contending parties. His judgment is called an award. The reference to him may be made, whether legal proceedings concerning the question referred have been instituted or not. The reference is made by writing under seal or otherwise, and even by parole agreements but in this latter case the submission cannot, as in the others be made a rule of court. (*See* AWARD.)

A'RBOR. The principal spindle or axis which communicates motion to the other parts of a machine.

ARBOR DIANÆ. *The tree of silver*, that metal having been called Diana by old chemists; it is made by putting quicksilver into a solution of nitrate of silver, which causes the separation of the silver in a beautiful arborescent and crystalline form.

ARBO'REOUS. Woody, or growing on wood. Herbaceous plants, the stems of which take a ligneous character, are called suffrutescent, or arboreous, according to the degree of woodiness which they exhibit. Plants which grow on trees are also called arboreous, such as the arboreous lichens, arboreous mosses, arboreous fungi, &c.

ARBORE'SCENT. Stems of plants which are at first herbaceous, and afterwards become somewhat woody and tree-like.

ARBORE'TUM. In Gardening, a place in a park or pleasure ground, or in a large garden or nursery, in which a collection of trees and shrubs, one of each kind, is cultivated. In such a scene there ought to be sufficient room for each species and variety to attain something like its natural size and shape; though, from the limited space generally allowed to collections of trees and shrubs in garden scenery, this is very seldom the case. The most complete arboretums in Europe, so far as respects the number of species collected together, are those of Messrs. Loddiges, at Hackney; and of the London Horticultural Society, at Chiswick.

ARBORICU'LTURE. (Lat. arbor, *a tree*, and colere, *to cultivate*.) The art of cultivating trees and shrubs, which are chiefly grown for timber or ornamental purposes. The culture of trees and shrubs grown for their fruits as food, is included under horticulture, and is sometimes called Pomology. The origin of arboriculture may be traced to the progress of agriculture; because, as population increased in any given country, it would become necessary to clear away the natural woods in order to grow corn, and other products of the field and garden. After this was done to a certain extent, a scarcity of wood, both for fuel and building purposes, would be found, and then recourse would be had to artificial plantations, or arboriculture. This art may be considered almost exclusively as one of modern times; because, though the Greeks and Romans planted both timber and ornamental trees, yet they did so only on a very limited scale, and near their houses, for the purposes of shade or ornament. They also planted the elm and the poplar, for supports to their vines; and they cultivated osier beds for the purposes of basket-making; but there is no instance on record of their having planted trees with a view of cutting them down either for timber or fuel. Wood for these purposes they procured from the native forests, to the management of which they paid particular attention. In Britain, the first plantations of barren timber on a large scale, with a view to profit, were made during the reign of Henry VIII.; and the kind of tree planted was chiefly the oak, which was raised from the acorn where it was finally to remain. Since that period, the formation of artificial plantations has been on the increase, more especially during the latter end of the last and the beginning of the present century, when the foreign supply of timber was comparatively limited by the war, and when there was a great demand for timber for ship-building. The discovery of coal mines, and more especially the increased facility of working them after the invention of the steam-engine, by providing fuel exclusively of wood, has rendered the necessity of preserving natural woods, and of forming artificial plantations, less in Britain than in any other country in the world. In consequence of this, there is no other country in which so small a portion of its surface is covered with forests; the woods being almost every where planted and maintained for ornamental purposes. On the continent of Europe, the practice of sowing or planting barren timber was little known before the time of Louis XIV., though the natural woods both of France and Germany were appropriated, and carefully preserved, for many generations before. At the present time, in consequence of the continental nations depending almost entirely on wood for their fuel, the care of the natural forests, and the formation of artificial plantations, form an important part of the duties of government. In North America, in the oldest cultivated parts of the country the formation of artificial plantations is barely commencing, while in the back settlements, or newest parts, the felling and clearing of timber is only now taking place.

The science of Arboriculture depends on a knowledge of the nature of trees, of the different agents in cultivation, and of the purposes to which trees are applied in the arts. The practice includes nursery culture: viz. propagation by seeds, by cuttings, layers, grafting, &c., and raising in beds and rows; transplanting, pruning, thinning, and, finally, felling, and the succession of kinds. The nursery culture is carried on in limited spots, called nursery grounds, or nursery gardens, by gardeners or nurserymen; and the other operations in woods, groves, rows, hedgerows, hedges, copses, osier holts, &c., by foresters, woodmen, or hedgers.

ARBU'STUM. The classical name for an orchard, hopyard, or vineyard.

A'RBUTUS. (Arbutus, Lat.; ar, *rough*, and boise, *bush*, in Celtic, according to Dr. Théis.) A genus of evergreen trees, with conical pallid flowers and a bullet-like succulent austere fruit, rough externally, and containing numerous minute seeds. Several species, all hardy, are known in gardens; the most common of which is Arbutus unedo, the most beautiful A. andrachne.

ARC. In Geometry, a portion of a circle or other curve line. The arc of a circle is the measure of the angle formed by two straight lines drawn from its extremities to the centre of the circle.

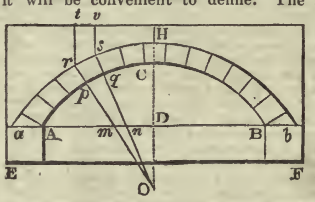
A'RCA. The name of a Linnæan genus of the Vermes Testacea, characterised by a bivalve and equivalve shell, having numerous sharp alternate teeth at the hinge. In modern systems the genus is placed among the Acephalous Lamellibranchiate mollusca, and is raised to the rank of a family (*Arcadæ*), subdivided into the subgenera Arca, Cucullæa, Pectunculus, and Nucula.

ARCA'DE. (Fr.) In Architecture, a series of arches crowned with a roof or ceiling, with a walk or passage thereunder. The piers of arcades may be decorated with columns, pilasters, niches, and apertures of different forms. The arches themselves are turned sometimes with rock-worked and sometimes with plain rustic arch-stones or voussoirs, or with a moulded archivolt, springing from an impost or platband, and sometimes,—though that is not to be recommended,—from columns. The key-stones are generally carved in the form of a console, or sculptured with some device. Scamozzi made the size of his piers less, and varied his imposts and archivolts in proportion to the delicacy of the orders he employed, but Vignola made his piers always of the same proportion.

ARCA'NUM. (Lat. *a secret*.) A term often applied to Chemical and Medical preparations by the old philosophers. Thus they called red oxide of mercury, obtained by the action of nitric acid, Arcanum corallanum; sulphate of potash, Arcanum duplicatum, &c.

ARCE'STHIDA. (Gr. ἄρκευθος, *a juniper berry*.) A small cone whose scales become succulent, and grow together into a fleshy ball.

ARCH. (Lat. arcus, *a bow*.) In Building, a structure of stones or bricks, or distinct blocks of any hard material, disposed in a bow-like form, and supporting one another by their mutual pressure. In describing arches some technical terms are made use of, which it will be convenient to define. The arch itself is formed by the voussoirs, or stones cut into the shape of a truncated wedge, the uppermost of which at C is called the keystone. The seams or planes in which two adjacent voussoirs are united, are called the joints; the solid masonry, A E and B F, against which the extremities of the arch abut or rest, are called the abutments; and the line from which the arch springs at A *a* B *b*, the impost. The lower line of the arch stones, A C B, is the intrados or soffit; the upper line, the extrados or back. The beginning of the arch is called the spring of the arch; the middle, the crown; the parts between the spring and the crown, the haunches. The distance A B between the upper extremities of the piers, or the springing lines, is called the span, and C D is the height of the arch.



There is considerable difficulty in determining the form which an arch ought to have, in order that its strength may be the greatest possible, when it sustains a load in addition to its own weight; in fact, the determination cannot be accurately made, unless we know not only the weight of the materials the arch has to support, but also the manner in which the pressure is connected; that is to say, unless we know the amount and direction of the pressure on every point of the arch. Supposing, however, that the arch has to sustain only its own weight, and supposing, further, that the friction of the arch-stones is reduced to nothing, a relation between the curve and the weight of the voussoirs may be found by comparing the pressures which are exerted on the different joints. Thus the pressure on any joint, *s q* for example, arises from the weight of that portion of the arch which is between *s q* and the summit C H. Now, the portion of the arch C *q s* H is sustained by three forces: the pressure on the joint *s q*, the pressure on C H, and its own weight. Let *s q* be prolonged till it meets C D in O, and let *n* be its intersection with A B. It is

a theorem in statics, that when a body is held in equilibrium by three forces balancing each other, these forces are proportional to the three sides of a triangle formed by lines respectively perpendicular to the directions of the forces. The three forces sustaining CqsH are, therefore, proportional to the sides of the triangle ODn; for the pressure on sq acts in the direction perpendicular to sq or On; the pressure on CH is perpendicular to DO, and nD is perpendicular to the direction of gravity. The pressure on sq is, therefore, to the pressure on CH as nD to DO. In like manner, the voussoir $prqs$ being so shaped, that rp, when produced, meets OH in the point O; the pressure on the joint rp is to that on CH, as mD to DO. Hence, the pressure on sq is to the pressure on rp as Dn to Dm. We are thus led to infer that the voussoirs ought to increase in length, from the key-stone to the piers, proportionally to the lines Dn, Dm, &c.; for in this case, the surfaces of the joints being increased in proportion to the pressure they sustain, the pressure on every point of the arch will be equal. It will also be observed that the angle nOD is equal to the angle made by a tangent to the curve at q, and the horizontal line parallel to AB; the angle mOD equal to that made by the tangent at p and the horizontal line; and the radius DO remaining constant, Dn is the tangent of the point of these angles, and Dm of the second; hence the pressures on the successive joints are proportional to the differences of the tangents of the arches reckoned from the crown. From this property, when the intrados is a circle given in position, and the depth of the key stone is given, the curve of the extrados may be found. When the weights of the voussoirs are all equal, the arch of equilibration is a catenarian curve, or a curve having the form which a flexible chain of uniform thickness would assume if hanging freely, the extremities being suspended from fixed points.

Such is the form which theory shows to be the best adapted to give strength to an arch, on the supposition that there is no superincumbent pressure. But it seldom if ever happens that this is the case, and therefore it is entirely unnecessary, in the actual construction of an arch, to adhere closely to the form determined on the above supposition. Indeed, on account of the friction of the materials and the adhesion of the cement, the form of the arch, within certain limits, is quite immaterial, for the deviation from the form of equilibration must be very considerable before any danger can arise from the slipping of the arch-stones. The Roman arches, which have resisted the attacks of time for so many centuries, are generally in the form of a semicircle. For bridges, it is better to employ a smaller segment of a circle; frequently the elliptic arch is preferred, on account of the beauty of its form.

It has not been satisfactorily ascertained in what country arches were first erected. They do not occur in any of the buildings of the Egyptians that can unquestionably be referred to an ancient date; and if they were not altogether unknown to the Greeks before the period of the Roman conquest, their principal uses appear to have been very little understood. They do not appear ever to have been employed in roofing the temples, or to have formed a part of ornamental architecture. By the Romans, however, the advantages of the arch were well understood at a very remote period. The Cloaca Maxima, which is an arched structure, is referred, with the greatest probability, to the age of the Tarquins; the arched dome is supposed to have originated with the Etruscans, and to have been employed for the convenience of the augurs, affording them a shelter from the weather, and permitting them at the same time to have a view of the whole range of the horizon. In the magnificent buildings erected under the empire the arch is of frequent occurrence; and it was by the Romans that it was first applied to its most useful purposes, namely, the construction of bridges and aqueducts. The Romans, however, appear to have given little attention to the graces of form in the erection of their arches, for they seldom deviated from the semicircle. It was in the middle ages that the pointed or Gothic arch was introduced, when Christians and Saracens vied with each other in giving beauty to their public buildings, by multiplying and combining arches in all possible manners. The associated architects of those ages, says Dr. Robison (*Ency. Brit.* art. *Arch*), having studied this branch of the art of building with so much attention, were able to erect the most magnificent buildings with materials which a Greek or Roman architect could have made little or no use of. There is infinitely more scientific skill displayed in a Gothic cathedral than in all the buildings of Greece and Rome; indeed, these last exhibit very little knowledge of the mutual balance of arches, and are full of gross blunders in this respect; nor could they have resisted the shock of time so long, had they not been almost solid masses of stone, with no more cavity than was indispensably necessary. It is somewhat remarkable that those architects do not appear ever to have studied or paid any regard to the theory of equilibrated arches. The form which they adopted was strong, and capable of resisting considerable inequalities of pressure, and hence the durability of their constructions. For further particulars on this subject, *see* Bridge. Dome.

ARCHÆO'LOGY. (Gr. ἀρχαιος, *ancient*, and λογος, *a description*.) The science or study of Antiquities, and chiefly, in ordinary language, of those minor branches of antiquities which are discarded from the contents of general history; as genealogies, national architecture, manners, customs, heraldic and similar subjects.

ARCHÆ'US. (Gr. ἀρχη, *principle*.) A term used by the old chemists and physicians to imply the occult cause of certain phenomena. Van Helmont and Stahl ascribe certain vital functions to the influence and superintendence of a spiritus archæus.

A'RCHAISM. (Gr. ἀρχαιος, *ancient*.) In Rhetoric and Literature, the use of an obsolete expression or phrase, giving an air of antiquity to the passage in which it occurs.

ARCHA'NGELS. A superior order of angels. The term occurs once in Scripture, being applied by St. Jude to Michael.

ARCHBI'SHOP, or METROPOLITAN. The primate of a province containing several dioceses. The term first came into use in the fourth century, and was then considered superior to that of metropolitan, and equivalent to patriarch, or bishop of an imperial diocese, such as Rome, Constantinople, Antioch, Alexandria, and Carthage.

ARCHDE'ACON. An Ecclesiastical officer, ranking next to the bishop. As deacons were originally attendants upon the bishop, so the archdeacon was one selected from among the deacons of several dioceses. His functions were confined to attending upon and assisting the bishop in the discharge of his spiritual duties and the management of his diocese, and had at first no jurisdiction. There are now more archdeacons than one in each diocese, the whole number in England being sixty; and they are employed by their bishops in visiting the clergy of the diocese, and in the dispatch of other matters relating to the episcopal superintendence.

ARCH-DUKE. A title originally assumed by various dukes, but in the sequel appropriated to those of the house of Austria by the Emperor Frederic III. in 1453. It is now strictly confined to the younger sons of an Emperor of Austria,

A'RCHER. (From the Latin arcus, *a bow*.) A bowman; one who uses a bow. The use of the bow in war may be traced to the earliest antiquity, and to the history of almost every people. The exact time when the English long-bow began to be used in war is not exactly ascertained: the Normans brought with them the arbalest or cross-bow; but from the reign of Edward II. the long-bow, the favourite national weapon, seems to have been fully established. When fire-arms began to come into use, various attempts were unsuccessfully made, by statute and proclamation, to prevent this ancient weapon becoming obsolete. In France the officers who attended the lieutenant of police were, before the Revolution, always called archers, although provided with carbines. Artillery is a French term, originally signifying archery, and the London artillery company were a fraternity of bowmen.

A'RCHETYPE. (Gr. ἀρχετυπος, from ἀρχη, *origin*, and τυπος, *type*.) The original of that which is represented in a picture or statue; and, figuratively, the reality which is shadowed out in prophecies or mysteries. Thus, in Theology, the death of our Saviour is said to be the archetype of the Jewish sacrifices, which were instituted as types of that event. (*See* Type.)

A'RCHIL. (A corruption of orseille, French.) A kind of purple dye obtained from the lichens, called *Rocella tinctoria* and *fuciformis*. It is chiefly procured in the Canaries.

ARCHIMA'NDRITE. A title of the Greek Church, equivalent to abbot; the word mandia signifying a *monastery* in the language of the Lower Empire.

A'RCHITECTURE. (Gr. ἀρχη, *beginning*, τεκτων, *artificer*.) The art of Building, according to certain proportions and rules determined and regulated by nature and taste. Architecture becomes an art at that period only in the history of nations when they have reached a certain degree of civilisation, of opulence, and of luxury. In an earlier state, it can only be reckoned among the trades or occupations necessary to the wants of mankind; its application is then very limited, its use little more than furnishing man with shelter from the waters of the heavens, and protection from the inclement vicissitudes of the seasons. At its birth, however, it assumes a character in all countries which in the sequel stamps it with such remarkable and distinguishing features, that in the summit of its grandeur the traces of its early origin are still discernible. Notwithstanding the interval of so many ages from its origin, we may even trace the general form of architecture to three distinct states of the human race, which necessarily influenced the nature of the

habitations suitable to each, and which ultimately became standard models of the art.

People whose dependence for their sustenance was on hunting the beasts of the field, as well as those who lived on the produce of the waters, from the natural indolence induced by those occupations and the little industry called for in such courses of life, would not be at an early period led to the construction of dwellings. They availed themselves of the natural caverns of the rock, or at most hollowed them out, for shelter and protection.

Nations occupied in a pastoral life, through a large portion of the year, obliged, for the sake of fresh pasturage, frequently to change their abode, and thus lead a wandering life, would find the most suitable dwelling one which they could remove with themselves; hence the use of tents.

Agriculture, which requires continued and active industry on the same spot, doubtless induced man to exert his energies in the erection of solid and durable dwellings. For his produce no less than for himself were they necessary, and the wooden hut with its sloping roof was the offspring of his wants.

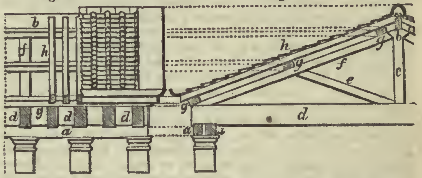
It is not, however, to be understood that in every country the art can be traced to a single principle, since among some nations, as will hereafter be seen in relation to Egyptian architecture, more than one will be found to enter into the combination. Causes, independent of the habits of the people, may have had their influence on the formation and taste of different species of architecture; yet will these in their turn be found dependent on the first named. In short, it is to the three states of mankind that we must refer to account for those striking peculiarities which prevent us from confounding the art of one people with that of another. In some of its details caprice may have had a share; but in every country the great leading forms spring from principles dependent on the different states of life we have just enumerated.

Those who have sought for the original types of this art in subterraneous temples and excavations exclusively, have fallen into error. These are found in almost every country. Many of them, such as the famous ear of Dionysius, and the quarries of Syracuse, had been the quarries that furnished stone for their neighbourhoods. By the help of history, and an acquaintance with the habits of the nation, by a knowledge of its origin and earliest mode of life, only, are we able to form a just opinion on its architecture. By the aid of these we recognise the origin of Egyptian architecture. A taste for subterraneous dwellings has existed among the Egyptians from the remotest period even to the present hour. The massive and colossal character of their edifices seems to bear a strong relation to hollow caves of rocks; and though the Egyptians grafted on this at a later period forms and details, whose types may be traced to carpentry, yet it is quite clear that the types of the masses must be found in a far different origin. The same passion for subterranean works appears in parts of Asia. The climate, and similar physical causes, would seem to have led to it. At Elephanta none of the parts appear to have been derived from imitation of any system of carpentry; the columns cut out of the rock, the short and massive proportions, the shape of the capitals, and their details throughout, point to an entirely different type for their invention.

In the architecture of China we have remarkable indications of timber construction. M. de Pauw justly observes, it is impossible to mistake the objects which served as models for the earliest Chinese buildings. In them the tent is the object of imitation, and this is quite in character with the primitive habits of the Chinese, who, like all the Tartars, were Nomades or Scenitæ, encamping with their flocks ages before they gathered into cities. Their cities of the present day exhibit the appearance of a vast encampment, and the great extent of them seems to indicate an insolidity of construction that will not allow of a number of stories above each other.

The wooden hut, then, which has been universally assumed as the model or type of all styles of architecture, and among all people, could not have been that of Chinese or Egyptian, though it unquestionably was that of Grecian architecture. The Greeks, working upon this, transferred to stone the forms of an assemblage of carpentry, a construction which gave birth to the members of the orders of architecture which are to this day the ornaments of our buildings. This style, be it remembered, belongs to a nation whose chief occupation is agriculture. In pursuing this theory, a few observations only will be needed. The first trees driven into the earth for the purpose of bearing a covering for shelter, were the origin of the insulated columns of the portico of a temple, and became one of the most splendid features of the art. As the trees were wider in diameter at the bottom than the top, so were the columns diminished in thickness as they rose. Scamozzi imagines that the mouldings at the bases and capitals of columns had their origin in cinctures of iron, to prevent the splitting of the timber; others, however, think that the use of the former was to elevate the shafts from the dampness of the earth, and thereby prevent rot. The architrave or chief beam speaks its origin. It was the great beam placed horizontally on the tops of the columns, and destined to receive the covering of the entire building. The joists of the ceiling lay upon the architrave, the space in height which they occupy being called the frieze, the ends of the joists in the Doric order bearing the name of triglyphs, from their being sculptured with two whole and two half glyphs or channels. Sometimes the ends of them are sculptured into consoles, as in the composite order of the Coliseum at Rome. The space between the triglyphs was for a long period left open, as we find from a passage in the Iphigenia of Euripides, where Pylades advises Orestes to slip through the metopes in order to get into the temple. These intervals were afterwards filled up solid; and in the other orders, the whole length of the frieze becomes one plain surface. The inclined rafters of the roof formed a projecture beyond the face of the building, which delivered the rain free of the walls. The ends of these rafters are the origin of mutules and modillions, the former whereof appeared in the cornice with their undersides inclined, as in the Parthenon at Athens. The form of the pediment followed from the inclined sides of the roof, which were regulated in respect of their inclination by the nature of the climate. (*See* art. ROOF.) Here, then, in the skeleton of the hut, may be traced the origin of the different members of architecture, which will be better understood by reference to the subjoined diagram. Figs. 1 and 2 exhibit the parts of

Fig. 2. Fig. 1.



a roof in section and elevation: *a a* are the architraves, or trabes; *b b* the ridge piece, or columen; *c* the king post, or columna of a roof; *d d* the tiebeam, or transtrum; *e* the strut, or capreolus; *f f* the rafters, or cantherii; *g g g g* the purlines, or templa; *h h* the common rafters, or asseres.

It has been suggested, but with less probability, that the main supports being by degrees placed at greater distances from each other than the strength of the architrave would safely admit, inclined struts were placed from the sides of the columns or supports to the underside of the architrave, to lessen its bearing, and that these gave the first notion of the use of arches in architecture. The subject has been pursued into many more details, on which our limits do not permit us to enter.

It is difficult, perhaps now impossible, to fix the exact period of the invention of architecture in Greece. Every art is perfected by slow degrees, and is the result of the labours of many. In the time of Homer, architecture does not seem to have been in so forward a state as to have been reduced to principles and proportions of a fixed nature. No mention is made by the poet of the use of the orders of architecture. The material seems with him of more importance than the form; and well selected and polished stones, more than fine proportions, are enumerated as the principal merit of the palace of Alcinous.

The Doric order, doubtless the earliest of the orders, remains without testimony which can satisfactorily assure us of the period of its invention. Its name is not alone sufficient proof that it was invented by Dorus, the son of Helen, and king of Achaia and Peloponnesus. It is possible it might have acquired its name from having been used at the celebrated temple which that prince built at Argos in honour of the goddess Juno; or it might have been, that, from the use of it by the Dorians, it obtained introduction into the other parts of Greece. Certain, however, it is that in the time of Alexander the Great the three original orders of architecture had been brought to perfection. Moral as well as physical causes had contributed to bring the arts to this state. Liberty, love of country, and ambition had made Athens the common centre of science and art. The defeat of the Persians at Marathon, with other victories, had restored peace to the country. In the period preceding the Peloponnesian war, there was a general burst of talent in Greece. In it the chisel of Phidias was employed; philosophy, eloquence, the military art, the arts and sciences, all conspired to give the epoch lustre. It was in this age that the Greeks commenced the rebuilding of the temples and edifices that had been destroyed in the Persian war, buildings whose ruins had been carefully preserved, perhaps, for the express purpose of keeping alive a remem-

brance of the danger that constantly menaced them as a nation. It was not, indeed, until after the flight of the general of Xerxes, and the victory of Themistocles, that a general restoration of their monuments was commenced, and the city of Athens rebuilt; a city whose edifices might be considered, as M. Quatremère de Quincy has well observed, as so many trophies of the victory at Salamis. This was the epoch of a pure and grand style of architecture, and, indeed, of art generally. The sculpture of that period is marked by the same character of purity, sublimity, and grandeur; and the Elgin marbles, fortunately now possessed by this country, exhibit a perfection which has never been approached by modern art, and which we scarcely conceive can be surpassed. It was in this age that the temple of Minerva, known by the name of the Parthenon (because that goddess preserved her virginity pure and inviolate), was erected; a building which displays, perhaps, the finest model of the Doric order.

The Ionic order seems, at this period, to have likewise received the finishing touches of that grace and elegance whereof it was susceptible. This order, passing from Greece to Asia Minor, seems, in that enervating climate, to have acquired elegance and finish at the expense almost of solidity. Whether we are indebted for its invention to the people whose name it bears, is of little importance. Upon the relation of Vitruvius no dependence can be placed. At the period, however, of the erection of the temple of Minerva Polias at Athens, which was about the time we have alluded to, it seems to have been brought to a state of perfection that leaves us nothing to desire. The capitals of this example are splendid specimens of decorated architecture.

By a substitution of acanthus leaves for the olive, laurel, and lotus leaves of the Egyptian capital, Callimachus is said to have invented the Corinthian capital, the feature which distinguishes the Corinthian from the Ionic order. The tale seems an idle one; but though almost threadbare, we cannot omit it, and will give it in the words of the author who has recorded it. "A Corinthian virgin, of marriageable years, fell a victim to a violent disorder. After her interment, her nurse, collecting in a basket those articles to which she had shown a partiality when alive, carried them to her tomb, and placed a tile on the basket, for the longer preservation of its contents. The basket was accidentally placed on the root of an acanthus plant, which, pressed by the weight, shot forth, towards spring, its stems and large foliage, and in the course of its growth reached the angles of the tile, and thus formed volutes at the extremities. Callimachus, who for his great ingenuity and taste was called Catatechnos by the Athenians, happening at this time to pass by the tomb, observed the basket, and the delicacy of the foliage which surrounded it. Pleased with the form and novelty of the combination, he constructed, from the hint thus afforded, columns of this species in the country about Corinth, and arranged its proportions, determining their proper measures by perfect rules."

The annexed diagram gives a representation of the circumstance, as usually found in architectural works: the reader, however is at liberty to make his own representation of it, which will most probably be as near the truth as that here given.

But few ancient examples of the Corinthian order are extant of so early a date as the age of Alexander. Its delicacy and slenderness render it very susceptible of the ravages of time; and it has been suggested, that the value of the material of which the columns and capitals of this order were made, excited the cupidity of the Romans to remove them.

The general opinion runs, that architecture, as well as the other arts, was carried into Etruria by the Pelasgi, at which period Doric was the only order in use in Greece, and was the only one, moreover, as far as can be judged of, adopted by the Pelasgi. But they changed its character, stripping it of triglyphs, and adding to it a base. — The Romans, who borrowed their earliest architecture from the Etruscans, adopted, under the name of Tuscan, this Doric order, thus cheated of its fair proportions, which is in truth but a species of Doric.

Rome appears to have been indebted to the people of Etruria for its earliest work of any note. It has always been supposed, that to an Etruscan architect was confided the construction of the immense sewer which drained the city, and in which might be discerned a presage of its future grandeur. The undecorated and simple art of Etruria suited the roughness and austerity of a warlike and then needy people. The art of architecture was long neglected among them. Their temples and palaces for a long period were protected from the seasons by a covering of nothing more than clay and straw. Marble and slavery entered Rome together, under the reign of Augustus. Effeminacy had been induced by the riches of the known world which centered in the city, whose inhabitants did not apprehend that slavery would follow in the train of the arts which were bound to the triumphal chariot.

Augustus, sensible that the only mode of tranquillising the people, when liberty was no more, would be by introducing the pleasures and luxuries attendant on the arts, exerted himself most zealously for their prosperity: his conduct on this point is sufficiently exemplified in the boast attributed to him, "That he found the city built of brick, and left it constructed with marble." Livy compliments him as the founder or restorer of temples, "Templorum omnium conditorem aut restitutorem." His patronage drew the most skilful Grecian artists to Rome, which now became the capital of the arts, and architecture reached all the perfection it could there attain. It was under Augustus that Vitruvius wrote his work on architecture, the only ancient text-book on the art that has reached us. It has been of late the fashion to decry the utility of this author. Those that have done so know little of the art. Though in matters relating to the history of architecture, our author deals somewhat in fable, the more important parts of his work are invaluable; and if one of the most profound architects that ever existed could dignify Vitruvius with the title of "our great master," it ill becomes the small fry of the present age to carp at him. Under Agrippa, the son-in-law of Augustus, the Pantheon was raised; one of the most magnificent examples of Roman grandeur. Amongst other superb structures he introduced baths, and constructed a considerable number of fountains, temples, &c. Under the successors of Augustus, the public buildings of the nation continued to increase; but the art began to degenerate in the reigns of Tiberius, Caligula, and Claudius. It could not be expected, that it would revive under such a personage as Nero, who deprived the finest statues of their heads to substitute his own portrait on their shoulders. He was, however, a great encourager of buildings on a highly decorated and colossal scale; witness the Domus Aurea, built for him by Severus and Celer, in which, from all accounts, richness and luxury themselves were exhausted. The wisdom and greatness of character of the emperor Trajan were infused into the buildings of his reign. The triumphal arches, but especially his column and forum, incontestably prove the rise of the art under his auspices, at which time his architect, Apollodorus, who raised the column to his memory, was highly patronised. Hadrian and the Antonines were also much devoted to the art, in which the former himself practised. Marcus Aurelius was so attached to the arts, that he became a pupil of Diognetus. Antoninus Pius, at ancient Lanuvium, built a country house, whose ruins at the present day astonish by their extent: as an index to its magnificence, it may be mentioned that a cock for regulating the supply of water, of the weight of forty pounds, and formed of silver, has been extracted from its ruins. The art, however, was then in its decline, and soon after disappeared under his successors. The arch of Septimus Severus is an extraordinary falling off from what it had been; and it is difficult, in such a short period, namely, since the reign of Marcus Aurelius, to conceive how the art of sculpture, more especially, could have become so debased. The details of what is called the goldsmiths' arch indicate the decay of good taste; its profiles are bad, and the ornaments overloaded.

For a short time architecture was prevented from entirely sinking, by the fostering hand of Alexander Severus; but the fall of the western empire completed its ruin: it is, however, from the reign of Gallienus, whose arch proves to what a state it was reduced, that we must reckon the total extinction of the arts. Architecture was indeed most likely to have survived the general wreck, and perhaps was not completely involved in the universal ruin. In an age when no sculptor existed, the baths erected by Diocletian exhibited a grandeur manifest even in their stupendous remains; it seems, however, that a bad taste must have reigned in the design of them, inasmuch as we learn from history, so overloaded with ornament was the edifice, that during the public games a great number of spectators lost their lives by the fall of some of the flowers from the ceilings and entablatures. Diocletian's palace at Spalatro is another proof of the enormous efforts made by that emperor, and of what the art could then do. About the same time, or in the time of Aurelian, were erected the extensive buildings in Cœlosyria, at Balbec, and Palmyra: vicious as they are in taste, one is astonished at the vastness of the plans, the boldness of the undertaking, and the funds lavished on their construction. There is nothing more instructive to a student on the rise, progress, and decline of Roman art, because the eye can almost cover it at one glance, than an examination of a series of Roman coins; and it is recommended, as likely to make an impression on the mind much stronger than the most elaborate treatises on the subject.

Though architecture, from various causes, was des-

tined to survive the other arts, its protracted existence could not extend beyond the period of the removal of the seat of empire to Byzantium. The endeavours of Constantine to erect his city into a metropolis that should rival Rome, which he spoiled of its treasures, were vain; all his efforts to embellish it with the most splendid monuments only proved how ineffectual are the attempts of kings to subject the arts to their power. That which Constantine left behind him in the eternal city and the rest of Italy fell a prey to the unrestrained fury of the Visigoths. The edifices which they afterwards reconstructed were from fragments of those they had destroyed; but their ignorance or forgetfulness of the stations and proportions in which they had originally been used, induced a sad confusion of the different members—entablatures inverted, and other grotesque arrangements, were to be seen in their buildings. The vast number of columns which the ruins supplied was used as piers for arcades, from which originated, beyond doubt, the plan of the Gothic cathedral, after its passage through various modifications. Quatremère de Quincy attributes (Enc. Method.) the use of the arch springing from columns to the ignorance of the builders of the period, who knew not, he assumes, the mode of connecting the different lengths of an architrave; but it seems scarcely probable that they, who so well knew the mode of connecting the voussoirs of an arch, should have been deficient in understanding the principle in question, which is either that of the arch itself or of the simplest joggling. From this period to the restoration of the arts at a late period, all sight of the original types seems to have been lost; and in the end arose a style under the name of Gothic, which will be separately treated of. Here occurs a considerable gap in the history of the art: all is dark on the subject, though the ancient taste does not seem to have passed away altogether. The first glimmer of returning light appears under Justinian, in the church of St. Sophia at Constantinople, in the sixth and seventh centuries. It was the chef-d'œuvre of the lower empire, and perhaps, indeed, the only specimen it has left us. The church of St. Mark at Venice rose in the tenth or eleventh century; it was the work of Greek architects. and is invaluable in tracing the history of architecture: its plan and its beautiful proportions remind the spectator of the magnificence of the ancients. Nearly about the same period other cities of Italy began to exhibit advances in the art. In 1013 the Florentines laid the foundations of the church of S. Miniato; but the most extraordinary monument of the period was the cathedral at Pisa, erected by Buschetto da Dulichio, a Greek architect, in 1016: this building is lined both inside and outside with marble, and the roof is borne on four ranks of columns of the same material. The commerce of the Pisans enabled them to explore the Levant, the islands on the coast of Asia Minor, Egypt, and Africa, for the most costly and precious marbles which were used in the work. Painters and sculptors were brought from Greece to embellish their buildings, and these contributed to introduce a better taste in the arts. Had Buschetto lived to form a school here, there can be little doubt that architecture would have been at once re-established; but such does not appear to have been the case, and the successful cultivation of it was, consequently, deferred for a time. The falling tower, as it is usually called, or campanile, at Pisa, was raised close to the cathedral in the twelfth century; its inclination evidently arises from a failure in the foundation; its style evinces but little progress as compared with the cathedral.

In the thirteenth century the church of the Virgin of Assisi was erected in Tuscany, and the castel del Ovo at Naples; the first by Lapo, and the last by Fucio, both Florentines. Nicolo da Pisa, their countryman and cotemporary, was employed on several edifices of consideration in Bologna, Padua, and Venice. His greatest work was the church at Padua, dedicated to St. Anthony, the sculpture in which is chiefly from his hand. The church, however, at Florence, della santissima Trinità, is his finest work, of which it is no small encomium to say that it was the admiration of so great a man as M. A. da Buonarotti. Arnolfo di Lapo built the church of St. Croce, and designed the cathedral also at Florence of Santa Maria de' Fiori. All the cities of Italy, indeed, at this epoch seemed to be emulous of outvying each other. Paolo Barbetta was engaged at Venice on the church of Santa Maria Formosa; many works were in progress at Bologna; the marble chapel of the church of Santa Maria Maggiore at Rome, about the year 1216, was executed by Marchione: every effort indicated the speedy restoration of pure art. These scintillations, however, of good taste were confined to Italy; in the other parts of Europe the Gothic style,—one, indeed, in some of its monuments, of stupendous grandeur, of which we shall treat in another article,—was prevalent, and soon afterwards in Germany carried to the utmost pitch of perfection. It was in the thirteenth and fourteenth centuries that the cathedral at Strasbourg was erected, under the designs of Irwin Steinbeck. The fourteenth century produced also in France and England some extraordinary Gothic structures.

In Italy architecture was fast approaching to a perfect restoration. John of Pisa son of the Nicholas whom we have just mentioned, was employed by his townsmen on the Campo Santo. This public cemetery was in the Gothic style, and is remarkable for the elegant simplicity of its plan and the beauty of its details. It is a singular link of the chain of history of this art: there is no difficulty in discerning the struggle in the mind of the architect to free himself from those Gothic shackles which seemed to hang on it as an impediment to an immediate return to the classic taste of the land, which became completely restored in Italy in the fifteenth century. The troubles throughout Europe were stilled at the time that Brunelleschi appeared as the restorer of genuine art, to which title he has a just and honourable claim. By a diligent investigation of the remains of ancient Rome, with the scale and compasses in his hand, he succeeded in reviving the ancient rules of art, the just use of the orders, and was himself the first to make a practical application of his discoveries. He well knew how to unite theory with practice, and from a profound acquaintance with the monuments of antiquity was led to the principles of sound construction, without which all other knowledge in architecture is useless.

The cathedral at Florence, begun in the Gothic style by Arnolpho, was reserved for Brunelleschi to finish, which he effected with a boldness worthy his genius. He surmounted the church with the tambour dome, which had, though projected by the original designer, been considered by the artists of the age more as a phantom of the imagination than a subject for reality. We have not room here to record the strange schemes that were proposed for carrying the project into execution; the facility with which the architect effected his object marks him as an artist, in that age, of surprising resources and ability.

The erection of the dome and cupola of Santa Maria de' Fiori opened the road for some of the grandest examples of human skill applied to the art: it was the subject of eulogy from Michael Angelo, and is still the astonishment of those who know how to appreciate the difficulties by which it was surrounded. The school formed by Brunelleschi spread by means of his disciples through Italy, and propagated the art in that revived state, which acquired liberal and enlightened protectors in the Medicis, the dukes of Milan, and many nobles of Italy, who opened their palaces to its professors, and the learned generally. These latter, who had after the arrival of cardinal Bessarion and other Greeks rendered Italy illustrious by their labours, soon opened the works of Vitruvius to the architect, in which they were considerably aided by Leo Battista Alberti, of the noble and ancient family of the Albertis of Florence, who himself did not disdain to practise architecture, as an art. Bold and ingenious as Brunelleschi his predecessor, his designs have the further charms of a grace and elegance which the former did not exhibit; and his work on the art, the only one at that period which could be put in competition with the ancient master Vitruvius, whose obscurity in many parts left much for experience to dissipate, displayed such vast stores of erudition, such a profound knowledge of construction, and so accurate an acquaintance with the works of the ancients, that it not only contributed to its firm establishment, but left little to desire on the theory and practice of architecture.

About the period that Alberti was thus engaged, an extraordinary work in the history of the art appeared from the pen of Francesco Colonna (in 1467), under the title of "Poliphili Hypnerotomachia," and published in folio by Aldus. This book is now extremely rare; it is replete with plates, some of great beauty, from wood blocks, and in it the author, in a supposed dream, promulgates sound precepts, noble ideas, and principles valuable to the amateur and architect. Felibien recommends to the artist its perusal, which he considers almost as necessary as that of Vitruvius. Indeed the poetic descriptions in it of pyramids, mausolea, colossal statues, circi, amphitheatres, temples, and palaces, seem to have made more impression at the time than the dry doctrines of Vitruvius, and Italy soon saw realised the poetic dreams of the author. In the period of a century and a half the cities of Italy were embellished with the works of Bramante, M. A. da Buonarotti, Raphael, Julio Romano, San Gallo, Baltazar Peruzzi, Giocondo, San Micheli, Sansovino, Serlio, Pirro Ligorio, Vignola, Palladio, Scamozzi, and a long list of others whose names are an honour to their country.

It was late before pure art reached this country. In it Inigo Jones is the father of architecture, and we, fortunately, still possess some of his beautiful designs. He can scarcely be said to have completely emancipated himself from the trammels of the debased Elizabethan style, as it is called, till the beginning of the reign of Charles I., which was a splendid epoch of the arts in this country. From many concurrent causes, the French

school of architecture has exhibited and still exhibits a very high degree of excellence, and may perhaps be fairly considered as holding the highest rank in the present day.

ARCHITECTURE, *Chinese*. As a description of the buildings of China would be out of place in a work of this nature, the subject of the present article is confined to a general view of the principles, the character, and the taste of Chinese architecture. To describe its general forms, for the purpose of identifying them, is unnecessary; they are universally known.

When we reflect on the limits to which in China the arts of imitation have for so long a period been confined, we are led to the conclusion, whatever be the cause, that the Chinese are deficient in that activity of mind which conducts other nations by degrees to perfection. In China the rise of the arts seems to have been constantly repressed by the state of mechanical drudgery and servitude in which the people are restricted. In their painting, for example, the most exact imitation of plants, fruits, and trees, is thought indispensable. A Chinese painter would think it necessary to count the scales between the head and tail of a carp he was about to represent; in other words, he is more of a naturalist than an artist. In China every matter relating to building is the subject of regulation by the police, which, rather than theory, governs its architecture. The laws of the empire detail and enforce with the greatest precision the mode of constructing a lou or palace for a prince of the first, second, or third rank, of a grandee, of a mandarin, &c. A man, unless he hold some office, who acquires a fortune by his own exertions is not allowed to build a house above his rank in society; his condition has nothing to do with it. According to the ancient law of the kingdom, the number and height of the apartments, the length and height of a building, are all regulated with precision, from the plain citizen to the mandarin, and from the latter up to the emperor himself. Herein alone we have sufficient to account for the poverty and want of invention in Chinese art.

In speaking of the principles of Chinese architecture, the word is not applicable in the same way as when we speak of classic architecture, but is meant to apply to those primitive causes which gave birth to it. Character and taste in every species of architecture are the necessary results of these elements. M. de Pauw has well described it, in respect of its principles and elements. It is impossible, he says, to be mistaken in the objects which were the models of imitation of their first buildings: they are imitations of tents, and that is in consonance with all our knowledge of the primitive state of the Chinese, who were, like all the Tartar tribes, nomadic. This, beyond doubt, is the true origin of their dwellings. However the missionaries of Pekin may have refuted M. de Pauw upon some inaccuracies, there canbe little hesitation in agreeing with him on this head. One of its strongest proofs is the form of the Chinese roof. Nothing but the form of a tent or pavilion could have given the idea of it; and though carpentry was for a long period made subservient to this form, reasoning from the progress of all inventions, it would be impossible to believe, where carpentry supplied the architecture, it should all at once have adopted combinations and coverings so light and at the same time so complex. There is another point of analogy with the tent construction, which is, that there is nothing like the appearance of a member of wood, similar to our architrave, destined to lie on the tops of the columns, and receive and support the remainder of the carpentry. The Chinese roofs, on the contrary, jut out beyond the columns, whose upper extremity is hidden by the eaves: hence the omission of the use of capitals. It is easy to perceive that extreme lightness must result from the imitation whereof we are speaking. The spirit and character of tents carried into the construction of cities might, at least in reality, be lost and altered by a change of materials. The semblance of lightness might be found in union with essential solidity of construction; the character would have been intellectually the same. Here, however, identity of material has contributed to the identity of the copy with the original. The Greeks, whose model was carpentry, copied in, as it were, a figurative manner, and the change from wood to stone soon removed the appearance of weakness and lightness that was found in the model. In China the material remains the same, and its architecture of wood still copies the model of wood; hence, the lightness of the original is transferred to the copy.

Lightness is the essential character of Chinese architecture; but there is another characteristic quality, both of the model and the copy, that is observable in the edifices of China, which is its gayness of appearance. In this respect scarcely any style presents a more pleasing effect. Its roofs, single and double, brilliantly painted, its gaily diapered porticos, the gloss over the whole surface, the harmony of this species of decoration, with the light and flowing forms of the buildings themselves, produce a sense of pleasure to eyes constantly accustomed to their contemplation, which would doubtless be disgusted with our cold and monotonous mode of decoration.

It is particularly in ornament and decoration that we are accustomed to investigate taste, which is the result of a combination of all the physical and moral causes that influence art. Yet, as every thing in architecture is connected by a sort of mutual relationship, it is difficult to fix the exact proportion that exists between construction and decoration, and especially in Chinese architecture. In speaking of ornament in architecture, one naturally recurs to sculpture for the purpose; but this is not found in Chinese architecture. With the Chinese ornament consists in varnishing columns, colouring roofs, coating walls with porcelain, and the like expedients. The figures painted on their buildings are connected with their religion, and the merit of the art is secondary. The art of ornamenting in China is a sort of patchwork, yet the parts of Chinese architecture are in unity with each other. A foreign style could never be made to amalgamate with it; it has been developed in a mode conformable to the wants of the country, and its duration for such a number of ages leads us to conclude that it will not lightly be abandoned by the people that have adopted it.

ARCHITECTURE, *Egyptian*. The preservation of the Egyptian monuments of architecture, in many instances so perfect as they still appear, is highly calculated to excite our surprise and admiration, inasmuch as ancient Egypt ceased to exist in its splendour long before the period of the earliest histories that have come down to us. Almost, as it were, separated from the rest of the world, by seas of sand as well as water, and bordering on the most savage tribes, it seems indebted to those circumstances for the protection its edifices have received. Had the country received as successors to its early inhabitants a powerful people, if rich and industrious cities had risen on the sites of the old ones, the temples of Egypt would doubtless have been used as quarries admirably suited to the purpose. Arabian hordes, and the almost barbarous and wretched inhabitants of the present day, have indeed built their villages on some of the ancient sites. The terraces of some of the temples serve as floors to modern habitations; and at Thebes, a town of two stories, or rather two stories of towns built on the ceilings of these everlasting ruins, indicate that the means of destruction have not been equal to the natural resistance of works of such solidity. No people ever existed whose whole feelings were so much a passion for ever-enduring monuments. Religion, a genius formed by that religion, government, habits, climate, materials, all united to confer on their buildings a durability as great as the power of man can confer; and the efforts resulting from such causes were successful.

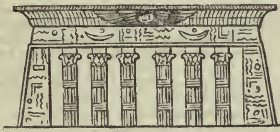
In a preceding article we have adverted to the three classes of mankind, whose different wants had an influence on their styles of architecture. It is not a forced supposition that the primitive inhabitants of Egypt used the excavations with which nature furnished them for protection against the heat of a sultry climate. As the inhabitants of Tyre, Sidon, and Palestine were indebted to their forests of cedar for becoming great workers in wood, so the Egyptians, from their earliest mode of life, from their quarries and the facility they acquired in hollowing them out, gained that aptitnde for working stone, and that high degree of perfection, so manifest in their works. It is true that their country is not the only one in which excavations abound; but in most other places these excavations have been caused by working them as quarries, and no trace of architecture or human abode can be perceived in them. In Egypt, on the contrary, where the caverns still furnish dwellings for the inhabitants, immemorial custom has assigned them to the use of mankind. The immense subterraneous apartments of Egypt must not be placed to the account of luxury in sepulture. Herodotus tells us, that the priests would not allow him to visit the subterranean apartments of the labyrinth in which they dwelt, and which were considered the most beautiful. Now, if this species of dwelling was used in the refined times of Egypt, à fortiori would it have been so in the earlier ages. Throughout Egyptian architecture its origin appears. A simplicity bordering on monotony; extreme solidity, amounting to heaviness; are its principal characters. There is entire absence of every thing that can be traced to a type of carpentry, as in the Grecian orders; hence it appears certain, that at least its type was different, and that type was cavern excavation. The exception that seems to arise from the use of columns does not militate against the theory; for decoration invariably refers to nature for objects of imitation; and nothing would sooner occur in decorating pillars in every style than the imitation of trees and plants, without referring to them as a type.

The honours of sepulture seem to have been the cause of the most stupendous of the Egyptian monuments Diodorus Siculus tells us, that the kings of Egypt ex-

pended sums upon their tombs more immense than other kings did upon their palaces. They were of opinion, he observes, that the frailty of the body during life was not worthy of a substantial and solid abode. They considered a palace like an inn, which is occupied by many in succession, and in which one stops but for a day. Their tombs, however, they considered as the real palace in which the abode was to be perpetual; hence, they spared no expense in rendering them worthy of such an object. Some have supposed that the pyramids were but immense cenotaphs, and that the bodies of the kings were interred in some neighbouring subterranean spot; in short, that these masses of stone were erected to mislead one from the spot which the body occupied. This, however, would not make them the less monuments of sepulture. Some have attributed to the pyramids a mystic, others an astronomical, purpose.

From Egypt were derived the principal mysteries that passed into other religions, and it was in the darkness of subterranean apartments that those initiations had birth, in which secrecy was the first law. Secrecy was there deified under the figure of Harpocrates. According to Plutarch, the sphinxes with which the entrances of their temples were decorated, signified that Egyptian mythology was mysterious and emblematic. The number of vestibules enclosed with a series of doors, prevented the temple itself from being seen. This, which none were allowed to approach, was small in extent, and in it the sacred animal or its image was preserved. It was in the galleries, porticos, and dwellings of the priests, that the large area which the temples covered was occupied.

Excepting some varieties in the plans of their temples, a sameness of character and uniformity is observable in them, which pervade their fronts, their general forms, and the details of their decoration; which latter are mostly of the hieroglyphic species, certainly the most monotonous of all decorations. To give the reader a general idea of the temples of the country, a diagram of that at Esneh is subjoined. With the Egyptians, heaviness seemed to be



ESNEH.

synonymous with strength, height with grandeur, and size or mass with power. Uniformity of plan is universal. The right line and square was never abandoned, and, as M. de Caylus observes, there exists no circular monument in this style. In the elevations the uniformity is still more striking, no division of parts, no contrast, no effect. It would seem that the ideas we have for judging of art, were no guide with the architecture of that country. Uniformity of decoration was an almost necessary result of the institutions of the country: the edifices were destined to receive certain inscriptions in symbolic characters, and were not allowed to be left in that respect to the caprice of the architect.

As respects the materials for building which the country afforded, we shall speak as concisely as possible. Though palm trees are found about the deserts of Lybia, and near Dendera, timber of every sort is scarce; indeed the soil is not suitable to the growth of trees. The most common next to the palm tree is the acacia; but, with the exception of the palm tree, most of the trees of Egypt are unfit for building purposes. The oak does not grow in Egypt, and the modern inhabitants import that from Arabia, as well as the fir which they use in their buildings. Brick seems to have been a material used from the earliest date; it was unburnt, being merely dried in the sun. Pocock says it is made of the mud deposited by the Nile, which is of a black colour, sandy, and mixed with flints and shells. One of the pyramids described by Pocock, was constructed with this species of brick, and unconnected by any cement. Bricks, however, were used after undergoing the heat of the fire at a very early period, as we learn from Scripture, Exod. v. 6., where we find the Israelites condemned to the labour of making bricks without straw to burn them. Stone of almost every description, marbles, and granite, were to be had in profusion; and these, as we have before observed, the Egyptians were very expert in working.

In construction there must have been considerable mechanical knowledge employed, for some of the blocks of stone were of enormous dimensions; and to form an idea of the quantity used, it is only necessary to mention that the walls of some of their temples extend to the extraordinary thickness of twenty-four feet. Indeed, the walls to the principal entrance of the gate at Thebes are no less at their base than fifty feet in thickness. The stones are all squared inside as well as on the external face; no rubble-work is to be seen; another cause of the surprising durability of their monuments. The roofs are all formed of single blocks of stone from pier to pier; no trace of the arch is any where discoverable. In the pyramids the passages are covered with stones inclined to each other, terminating in a point, one stone lapping over the other.

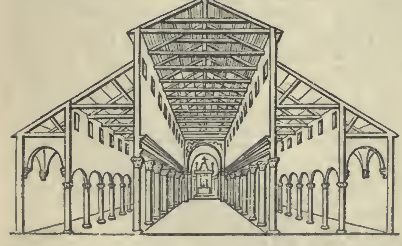
The Egyptian temple, unlike that of the Greeks, which may be almost all taken in at one view both interiorly and exteriorly, consists of an assemblage of porticos, courts, vestibules, galleries, and other apartments communicating with one another, each of which in size had little relation to the rest of the edifice. They were usually in a spot surrounded with walls; and those which were not so surrounded were inclosed in front by a wall engaged to the columns, and extending in height about a half or a third of the shaft. Strabo says that at the entrance of temples was a large paved court three or four times or even more of its width in length, which the Greeks called the dromos. This was ornamented with sphinxes in rows. Through the dromos was the propylum or fore portico; thence to another, and from that to a third, the number of them not being fixed. Beyond the propyla was situated the temple itself (or naos), which consisted of two parts, the pronaos or fore temple, and the secos or sanctuary, which in Egyptian temples was very small, and contained a figure of the divinity, usually represented under the form of some animal. Some of these temples were of very large dimensions; that of Jupiter at Thebes was more than 1400 feet long and 300 feet wide, exclusive of the porticos that led to it. The forms of all the plans are either square or rectangular. The art of designing a plan in modern architecture becomes difficult from the necessity of keeping the apartments within such bounds that they may be covered or roofed, and of arranging the decorations, and of counterpoising thrusts; but the Egyptian architect had no such difficulties to contend with. Columns were brought to the spot and covered at once with masses of stone, all combining without much contrivance with the exterior walls: hence, the abundant use of columns in the interior of their buildings. Great regularity appears in their plans. The temple at Philæ, evidently from its being suited to the form of the island on which it was built, is the only exception to the observation. Their intercolumniations are narrow, rarely exceeding twice and a half the width of the column, and usually not more than a diameter and a half. The elevation is always uniform and monotonous, always of one story, and without columns above columns. The pyramidal form seems to pervade every edifice, and the result must be great solidity. Their columns may be considered as of two sorts, circular on the plan, and polygonal; the former differ only among each other by their being sculptured or not with hieroglyphics. Those representing as it were bundles of rods or trunks, are generally encircled at different heights with bands like the hoops of a cask, generally in two or three ranges of three, four, or five each. This part of the arrangement seems to have been quite arbitrary. The polygonal column frequently occurs, but more generally where the edifice has been formed out of a rock or quarry. All the columns rise from their bases in right lines, diminishing to the top, without any appearance of entasis or swelling. One can hardly say that any precise proportion is preserved between their height and their thickness. In describing them, we can only say that they were short, thick, and of enormous diameter, the latter in some cases extending to as much as eleven feet. What are understood by pilasters are not found in Egyptian buildings, though some quadrangular columns might give that idea, excepting only in the small sepulchral chamber of the great pyramid. Bases are also rarely found; but the capitals of their columns exhibit great variety. In general form they are either square, vase-formed, or swelled; some of them are very elegantly shaped and decorated with the lotus, the palm branch, and other kinds of vegetation, and occasionally with the human head. They are usually without abacus, and are connected to the architrave by a small die or square block out of the same piece of stone as the capital. The entablature rarely, if ever, consisted of more than an architrave surmounted by a huge cavetto, which finished upward with a bead or fillet. This cavetto was frequently ornamented with glyphs and other indentations of the surface, and the wings of the vulture in the centre. The covering of the temple was a flat terrace, though there are no proofs, by the remains of steps to ascend to it, that it was so used.

Some years ago a question was proposed by the French Academy of Inscriptions and Belles-Lettres, whether the Greeks borrowed their architecture from the Egyptians; that question has been well answered by M. Quatremère de Quincy, in the Encyc. Method., to whom we are indebted for much in this article, and the substance of his answer is as follows: — There is no such thing as general human architecture, because the wants of mankind must vary in different countries. The only one in which the different species of architecture can approach each

other is intellectual: it is that of impressions which the qualities whose effects the building art accomplishes can produce upon the mind of every man, of whatever country he may be. Some of these impressions result from every species of architecture. Architecture sprung as well from the huts of Greece, as from the subterraneous excavations of Egypt and the tents of Asia, and from several mixed principles to us unknown: thus the use of the word architecture is absurd. We ought to name the species; for between the idea of architecture as a genus and as a species, there is the same difference as between language and tongue; and to seek for a simple origin of architecture, is as absurd as a search would be after the primitive language. If so, the hut of Vitruvius would not be an ingenious fable, as some have said, but it would be a ridiculous falsehood if he had pretended that it was the type of all architecture. Vitruvius, however, spoke only of Grecian architecture; and if in Egypt there exists another type, that only proves that the hut was not the type of Egyptian art, but that it was that of Greek art, and that theory would be fabulous which pretended to be universal. We will conclude this article by adding that similarity between certain forms of ornament, certain details borrowed by the one from another, prove nothing more than that between the people by whom they were used there was some interchange of commerce or other intercourse, which could not long subsist without some sort of necessary transfusion of the inventions and habits of one of those countries into the habits, manners, and customs of the other.

Architecture, *Gothic.*—To form a correct idea of the Gothic style of architecture, it will be necessary to trace its progress through one very different in its details, though not exactly so in its plan and arrangements. Its type is of a mixed character, and not, as we have seen in the two foregoing articles, founded on the habits of a people. Though a search into the origin of the pointed arch is an idle and useless inquiry, it will be necessary in the end to glance at that as incidental to the style under consideration.

The ancient basilica, which derived its name from basileus, king, and oikos, house, was the part of the king's palace in which justice was administered to the subjects. The building for this purpose retained its name long after the extinction of the kingly office, and was in use with the Romans as well as with the Grecians. Vitruvius does not, however, give us any specific difference between those erected by one or the other of those people. He has (ch. i. l. 5.) given the details of its form and arrangement, and we refer the reader to his work for the particulars of it. The name was afterwards transferred to the first monuments of Christian worship, not because, as some have supposed, the first Christian emperors used the ancient basilicæ for the celebration of their religion, but more probably with reference to the idea of sovereignty which the religion exercised, though no assertion is here advanced that such a conclusion is necessarily to be drawn. There is no doubt that the most ancient Christian basilicæ were constructed expressly for the purpose of that religion, and their architectural details sufficiently point to the epoch in which they were erected. Nevertheless these new temples of religion, both in the whole and in the details, borrowed so much of those of the ancient basilicæ, that even on this account it is not surprising that they should have retained the name. A general notion of one may be formed from the annexed diagram, which will immediately



show how admirably it was suited to the reception of an extremely numerous congregation. The numberless columns which were at hand, the remains and ruins of ancient edifices, were put in requisition for the construction of these basilicæ, of which, adopting the former buildings of that name as the type, they proportioned the elevation to the extent of the plans, and in some cases decorated it with the richest ornaments. Instead of connecting the columns together by architraves on their top, which were not at hand as were the former, arches were thrown over, not only to connect them, but that thereon walls might be carried up to bear the roofing. On this sort of substruction, vaults could not with safety have been borne. From these the obvious and natural step was to piers, connected by arches and ornamented with pilasters or columns. The piers underwent a change by being made circular on the plan; these again, for the purpose of giving the interior a lighter appearance, were made polystylic or in ribs, and ultimately received a vaulting and cross vaultings in character with their plan below. Though the practice of vaulting large areas, and the pointed arch, did not appear till a considerable time after the building of the first Christian basilicæ, it is to be observed that the Temple of Peace at Rome had previously to that period exhibited a specimen of the profound knowledge of the Romans in the practice of vaulting; in that example groined vaults of very large dimensions were borne on entablatures and columns. Nor does this knowledge appear to have been lost in almost the last stage of decline of Roman architecture under the emperor Diocletian. In the baths of this emperor are to be seen not only groined vaults in three divisions, whose span is nearly seventy feet, but at the back of each springer a buttress, precisely of the nature of a flying buttress, is contrived to counteract the thrusts of the vaulting. If a comparison be made between this large hall (now used as a church), of the baths of Diocletian, with the nave of a Gothic church, the difference will be found to be more such as must result from the nature and employment of the materials, than from difference of style. From the age of Constantine down to the ninth century, the edifices within the limits of the Roman empire are but degraded specimens of Roman architecture; and there is no evidence from their remains (few indeed they are) that the Goths and other barbarians who devastated Italy had any other influence on the arts than hastening, perhaps, that fall from which it would seem nothing could have saved them. We quite coincide in the opinion of Möller, who in the text to his Deukmaehler der Deutschen Baukunst says, " I cannot possibly agree to the opinion of those connoisseurs who ascribe an individual and peculiar style of architecture to the Goths and Lombards in Italy and Spain, to the Franks in Gaul, and to the Saxons in England." The Roman architecture of the fifth and sixth centuries was the model, and the constant correspondence from every part with Rome kept up an influence from thence over the arts and sciences. Fine proportions were lost, and the art completely degenerated into a servile imitation of earlier forms. The art of construction and the preparation of materials did not, however, fall away from solid building. The basement of the palace built, it is supposed, at Terracina, by Theodoric, the Gothic king, who reigned in Italy from A.D. 493 to 525, is in the Roman style. So also is the church of St. Apollinaris at Ravenna; and the circumstance mentioned by the writer above named, who up to the period at which we are writing, D'Agincourt excepted, is the only writer of any value on the subject, of the employment by Theodoric as architects of one Aloysius, an architect called Daniel, and the well known Boetius, a native and senator of Rome, is a strong corroborative proof that the edifices of the Goths were built by Romans and in the Roman style. Neither does it appear likely that upon the irruption of the Lombards in the year 568, after the sway of the Goths had lasted so long, they should have established a style of their own. They were a rude people, whereas the Goths, we know, had become quite a civilised nation, whose style was suited to the wants and habits of the country. It is true that D'Agincourt ascribes to the Lombards the church of St. Julian, near Bergamo, and some others; but it has not been proved that the churches in question were really erected by the Lombards. The appellation of Lombardic to the style of church building which existed in France and

9th to 12th century. After the 12th century.

Germany stands on too slender an assumption to be admitted; indeed it has been demonstrated by Maffei, Muratori, and Tiraboschi, that neither the Goths nor the Lombards introduced any style in particular, but employed the architects whom they found in Italy. The late learned Mr. Dallaway says, in his Discourses upon Architecture in England, that "at the beginning of the eighth century all Europe formed but one Gothic kingdom;" and it is certain that anterior to A.D. 800, there are very few Gothic remains. From that period to the general introduction and use of the pointed arch in the twelfth century, the leading form of the churches was a

parallelogram, consisting of a nave, side aisles, a transept on each side forming the arms of a cross, and beyond the intersection of the transept with the nave was placed a choir, terminated by a semicircular added building called the apsis. The whole of these buildings were constructed with very thick walls, pierced with comparatively small openings. In the vaulting of the nave and aisles, and over all windows and doors, the covering was semicircular. The nave was lofty, and was mostly constructed with groins. The section A shows the general appearance of the arrangement. The gables were not much inclined, and in the upper part of the building rows of small pillars appear in the walls. The profiles of the different members are all of Roman origin: many are correctly copied in their forms. In this country endeavours have been made to subdivide this style into Saxon and Norman. The subdivision is useless. Speaking of architecture as an art, they are of the same school, and the style has been by Möller called the Christian or Roman style; by others, the Romanesque style; either of which are appellations suitable, and would sufficiently carry their meaning with them.

Towards the latter end of the twelfth century and in the beginning of the thirteenth, very considerable deviations were introduced. For the flat southern gable, says Möller, was substituted the high northern roof, which brought with it the pointed arch in place of the semicircular one, being a consequence necessary for the harmony of the parts among each other. With the elevation of the roof and vaulting came a slender proportion of towers, columns, capitals, &c.; and at the latter end of the century the flat pilaster spreads outwards, and is converted into a flying buttress. At this period the edifices were in several respects anomalous, inasmuch as we have a mixture of circular and pointed arches, pillars, and vaults intersected by horizontal cornices and the like. The duration of this heterogeneous style was very limited, being immediately succeeded by the universal prevalence of the high pitched gable and the pointed arch. The plans of the edifices were not materially changed except in the omission of the apsis, and a general idea may be formed of the whole by an inspection of the section marked B in the preceding cut. It appears incontrovertible that the Germans were the first to carry this style to its highest perfection. As early as A. D. 1248, the cathedral of Cologne was begun upon its present plan, a building which, if finished, would have been the grandest and most beautiful in the world. Erwin von Steinbach, soon after 1276, built the porch of the minster of Strasburg; a building more, perhaps, esteemed than the last, because nearly brought to a state of completion. The style which we have just been describing wants no other distinctive appellation than the pointed. Imagination seems after its establishment to have been tortured to invent new combinations of ornaments and tracery. It overstepped at length the true bounds of architecture, and was abandoned in the sixteenth century for the introduction and restoration of Roman, or, more properly speaking, Italian architecture. The author above quoted says that the architects of these times were adapted to their age, and that their works are the result of the time in which they lived; and that, however we admire and imitate these works, we are not able to reproduce them, on account of the circumstances under which the style arose not being the same.

The powers of mechanical construction exhibited in the pointed style are such as to excite our admiration and astonishment; the exact calculated proportion between strength and burthen, the counteraction of thrusts of vaulting, and the consequent lightness and boldness resulting from those calculations, evince an intimate acquaintance with the most important and useful qualification which an architect can possess, namely, the production of the greatest possible effect with the most limited means. This qualification was possessed by the architects of the thirteenth century in the highest degree, and to an extent quite unknown to the Greeks and Romans.

The name Gothic, which has been given to the styles of architecture just described, is, from what has been advanced, very inappropriate. It is, however, now no longer used in its application as a term of reproach. That the Goths had no share in its invention or perfection is quite clear, and, as Mr. Dallaway justly observes, "it is not worth the dispute whether the Gothic power was ever annihilated in Europe, or whether they subsisted in the conquered countries as a separate people." We subjoin an enumeration of the different hypotheses upon which endeavours have been made to account for the invention of the pointed arch. 1st. Warburton (notes to Pope) asserts that Gothic architecture originated in Spain under Moorish architects; its type being an avenue of lofty trees, the intersecting branches at top forming the sharply pointed arch, and the stems of a clump of trees being represented by columns split into distinct shafts. Warburton, however, not only lost sight of accurate chronology in his hypothesis, but is wanting in originality. Stukely had made a similar remark. Spence (Anecdotes of Pope) puts in his claim before Warburton, and Sir Christopher Wren had a notion that the invention belonged to the Saracens; so also had Thomas Warton. 2d. The hypothesis of Sir James Hall, ingenious but far from satisfactory. He first assumes that the first English churches were made of wicker work, and then states them to have been the prototypes of those built with stone, furnishing, that is, the wicker work, from its sprouts, the original examples of every ornament or particle that was introduced. 3d. That it is founded upon the structure of framing in wooden buildings. 4th. That of Mr. Murphy, the editor of the celebrated work on the convent of Batalha, in Portugal. His reasoning is as follows: The pyramids of the Egyptians are tombs; the dead are buried in churches, and on their towers are pyramidal forms; consequently, the pyramids of the towers indicate that there are graves in the churches; and as the pyramidal form constitutes the essence of the pointed arch style, and the pyramids of the towers are imitations of the Egyptian pyramids, the pointed arch is derived from the latter. We cannot suppose the reader can require any refutation of such a set of syllogisms as this. 5th and last is that of the late Dr. Milner, who, whatever may be the opinion on his theory of its origin, was well informed upon and intimately conversant with the general subject. Dr. Milner says that it arose from the imitation of pointed arches, generated by the intersection of semicircles, thus:

There are, however, many reasons why this account is not satisfactory, though it must be admitted that in the Romanesque style this combination is frequently to be found. Dr. Milner seems entirely in his hypothesis to have lost sight of a circumstance that is quite familiar to every artist, namely, that it is a principle in all art that the details of every style are subordinate to and dependent on the masses, and not the converse; how then could it have been probable that the leading features of a style so generally used should have had its origin in an accidental and even unessential decoration like that of the learned doctor's theory. In short, none of the hypotheses mentioned can be considered satisfactory; and, as Möller observes, the solution of the question, whether the pointed style belongs to one nation exclusively, is attended with greater difficulties. After all, the problem for solution is not who invented the pointed arch, but in what way is its prevalence in the thirteenth century to be accounted for.

ARCHITECTURE, *Grecian*.—Grecian architecture, which was transplanted after its perfection to an Italian soil, where it assumed almost another form, will not require an extended notice in this place. The particular detail of the changes it underwent will be found in the articles DORIC, IONIC, and CORINTHIAN orders. The architecture of the Greeks, adopted afterwards by the Romans, has, indeed, with certain modifications, long been the architecture of the world. Its origin and types have already been considered in the article Architecture, and an explanation of its terms will be found under their several heads in this work. We shall, however, present a cursory sketch of its rise and progress.

Cadmus, about 1519 B.C., is reported to have introduced into Greece the worship of the Egyptian deities, and also the practice of quarrying stone; to him also is attributed the instruction of the Greeks in the art of fusing and working metals, from which period it is said the Greeks rapidly advanced in civilisation. According to Pausanias the Greeks at an early period had raised some extraordinary structures, such as the treasury of Minyas, king of Orchomenus, and the walls of Tiryns, which that author describes as a work worthy the admiration of every age. From the Homeric writings we find that the form of government was patriarchal, that the chief buildings were the palaces of the princes, and that the altar was the only structure for sacred use, and that even this was little more than a hearth, on which the victim was prepared for the meal; for, until after Homer's time, no regular priesthood existed in Greece. It seems probable that the temple was not used until the kingly and sacerdotal offices were separated. It would be difficult, perhaps now impossible, to trace the degrees from the use of the simple altar to the establishment of the regular temple, or when the latter became a necessary appendage to the religion of the country. Eusebius and others have conjectured that the early temples were but stately monuments, raised in honour of the primitive heroes who had conferred benefits on mankind. In respect of the houses of the Greeks, they appear to have been simple in plan, and at an early age consisted of two stories, as was indeed the case with the dwellings of the East mentioned in the Scriptures.

Between the period commonly assigned to the siege of Troy to the time of Solon and Pisistratus, we have few means of investigating the progress of Grecian art. Goguet (*Origine des Loix*) says that Asia Minor was the cradle in which architecture was nursed, and thinks that

to this country we are indebted for the invention of the Doric and Ionic orders. All authors seem to admit that the Corinthian did not appear till some time afterwards, and that it had birth in the mother country, and not in the colonies. Perhaps the earliest temple recorded is that of Jupiter, at Olympia, which, according to Pausanias, must have been built 630 years before the Christian era. If Livy be right, that of Diana at Ephesus was of a period little less remote, and at this time the science of mechanics was in its infancy; for even in the time of Thucydides, though the powers of the crane were known, they were not compendiously applied for the purpose of raising weights.

Admitting that the system of imitation in the Doric order was founded on the elementary forms and parts of the hut, it was in that case guided by the principles that nature herself adopts in her operations, otherwise no bounds would have limited the caprice and imagination of its improvers. In the copy, no part is precisely similar to the model; but an analogy, and that very strong, is observable. The proportions and parts of the Doric order, in different examples, plainly indicate that the Grecian artists considered themselves restricted only by general rules, inasmuch as we find them varying the height of the Doric column from four diameters to six and a half in height (*see* Doric Order), while the height of the entablature varies in terms of the diameter from 1·72 to 1·97. Lord Aberdeen, in his Inquiry into the Principles of Beauty in Grecian Architecture, has suggested that the height of the capital of this order, in terms of the upper diameter of the shaft, will afford some indication of the comparative antiquity of an example; but there is no ground for the suggestion, as the author of this article has pointed out in a treatise on Grecian Architecture prefixed to his edition of Chambers's Civil Architecture. The intercolumniations used in the Doric order at Pæstum, Corinth, and Segesta, and the Parthenon, are equal to about one diameter of the column. They are about a quarter of a diameter more at the Temple of Theseus, whilst in an example at Syracuse they are somewhat less than a diameter.

The age of Pericles exhibited almost all that art could be imagined to accomplish; the Peloponnesians and their colonies had erected the temples at Corinth, Nemea, Pæstum, Syracuse, and other places in Sicily: thus, in a space of little more than three hundred years from its introduction, it appears that the art was raised to the summit of perfection. It is probable that the Ionic order is not far behind the Doric in antiquity. In the former, the different examples exhibit a variety not less to be noticed than that we have observed in the latter order. The height of the Ionic column varies in the three examples of the temples on the Ilyssus, Minerva Polias, and Erectheus, from eight diameters and a quarter to nine and a half in height; but in the heights of the entablatures there is not so much variance. The cornice of the Grecian Ionic may be considered as bearing a constant ratio to the whole height of the entablature, as two to nine; while the whole height of the latter seems nearly constant at two diameters in height. This order received the addition of a base to its shaft, which was wanting in the Doric order; but, for the varieties, the reader will refer to that article in this work. The volutes, which are its distinguishing features, are found with many varieties. In the temple on the Ilyssus, that of Minerva Polias at Priene, and that of Apollo Didymæus, the volute contains only one channel between the revolutions of the spiral; whereas in those of Erectheus and Minerva Polias, at Athens, each volute has two distinct spirals with channels between them. In the former of these two the column terminates with an astragal and fillet, just below the eye of the volute; in that of Minerva Polias, with a single fillet. In each, the neck of the capital is ornamented with honeysuckles. The shafts are usually cut with flutes of an elliptical form, to the number of twenty-four. These flutes vary from those of the Doric order, in their separation from each other, through the intervention of fillets.

The distinguishing feature of the Corinthian as of the Ionic order is the capital. In a preceding article the elegant story by Vitruvius of its invention has been told, because that has been rendered almost sacred by tradition; but it must be observed, that long before the age of Callimachus, its reputed inventor, perhaps even before capitals or columns themselves were known to the Greeks, the leaves of the palm tree, the flowers of the lotus, and even volutes, were applied as ornaments to the capitals of Egyptian architecture; and, be it observed, the form of the bell itself in no small degree resembles the contour of the lotus flower. The Greek Corinthian and the Egyptian capitals of this class, are more distinguishable by their respective heights than by peculiarity of other features. The former, however, has a lightness and elegance which the Egyptian, perhaps from moral and political causes, never attained; but if even a slight intercourse between the two countries existed, there would appear considerable proof of the identity of the primitive inventors.

Our knowledge of the Greek Corinthian order is unfortunately circumscribed, from the destruction and decay to which from its extreme delicacy it was exposed; nevertheless, under even these circumstances, the few examples that remain induce a supposition that it was not in such high estimation as those we have already named, inasmuch as the only examples that have come down to us are those of what is called the Tower of the Winds, and the Choragic Monument of Lysicrates, both at Athens. But the former of these is scarcely to be classed among examples of Corinthian, and the latter (as we now understand the Corinthian order) is in some respects a little outré in the species. In the Choragic Monument the height of the entablature is somewhat less than a fifth of the total height of the order. The base varies little from that of the Ionic order, excepting in the non-appearance of the horizontal fluting in the upper torus.

To the orders enumerated may be added one scarcely to be named here, because apparently under no rules which regulated its proportions, namely, the figures called Caryatides, which were employed for the support of an entablature. For the supposed account of their origin, the reader is referred to the article Caryatides.

The only subject remaining for notice, under this head, is that of the roofs of the Grecian temples. Their roofs consisted, of course, of two inclined sides, which at the ends formed a pediment. From experience it was soon found that the angle at which the sides of a roof should be inclined to the horizon, should be such as effectually to shelter the interior of the building from the inclemencies of the seasons. Hence greatly inclined roofs are indispensable in northern climates; the reverse as the climate approaches the equator: but this will be more fully explained under the article Roof. Here we shall merely state that, according to the hypothesis, the inclination of the sides of a roof should, for the latitude of Athens, be 16¾ degrees. The actual inclination of the roof of the temple of Erectheus is 15¼ degrees, temple of Theseus 15 degrees, the Parthenon 16 degrees, and that of the Propylea 14½. Comparing the law with the Roman examples, the climate would require an inclination of the sides of the roof with the horizon of 22 degrees, and the variation between the examples remaining is from 22 to 24 degrees.

The invention of the arch does not at present appear to belong to Greek architecture. It was one of the most important inventions in the history of architecture; but so disputed a point is not to be touched upon in a work of this nature. We incline to the opinion that its invention does not belong to the Greeks, for this simple reason, that they have left us no examples of it that have come to our knowledge.

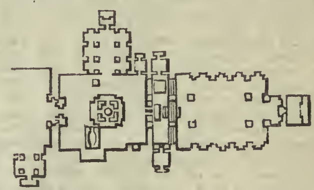
Architecture, *Indian*.—It is very properly observed by M. Quatremère de Quincy, that, in spite of all theories, an infallible mode of estimating the state of the architecture and other arts of any people is by their representations of the human form. Every people, he says, who during a number of ages have persevered in falsely representing the figure void of all proportion, and according to a certain barbarous and ignorant routine, must be convicted of a want of that sentiment which leads to a knowledge of truth, and of that intelligence which knows how to find in nature rules for the choice of forms and arrangements applicable to the art of building. Every people who do not manifest in their works this conformity to nature must be ignorant of the arts of imitation, and all their productions must be the result of an irregular taste. These observations particularly apply to Indian architecture, whose exact antiquity is still a problematical question. In a country abounding with deserted monuments, where are found the traces of an ancient language now no longer spoken, books no longer understood, the vestiges of a religion whose creed and allegories seem to have had some resemblance to those of Greece, one is naturally led to surmise that civilisation existed at a very early period. These opinions would seem corroborated by the extraordinary chronologies which the modern Indians have produced as incontestable authorities for their remote antiquity. The chronology, however, of the Hindoos will not bear the test of strict investigation; neither has any inscription or historic monument been discovered, nor annals found, which give us an idea of the changes, revolutions, or prosperity which the country may have experienced. It is, however, certain, that India has been possessed and successively invaded by several people, and that its creeds, as well as its religious allegories, indicate such great diversity and mixture of opinions as might lead us into every species of error in matters of historical research.

It is natural to suppose, that the subterraneous or excavated monuments of India are prior in date to raised or constructed works; and yet, in point of fact, there are in the former neither less details, less caprice in form, nor less profusion of fantastic ornament, than in the latter. Hence the monuments themselves afford us no

clue to their respective antiquities. M. Meiners contends that none of them are more ancient than the vulgar era, whilst M. Langles, a critic of no ordinary sagacity, is of an opinion rather different, namely, that Indian art was brought from Egypt, and that traces of such an importation are very distinctly marked, as well as that Greek art is strongly indicated in them. If, however, those monuments, whose date we have good reason for believing is recent, exhibit the same taste as that manifest in those monuments whose date is unknown, we may fairly assume that the same style of architecture existed in this country at a period preceding the conquest of Alexander and the epoch in which this early civilised country had intercourse with the Grecians. Though we have no historical nor chronological guides to enlighten us on the subject of Indian architecture, it is to be recollected that there is some analogy between the irregular taste that prevailed in India, and that of the rest of Asia. Southern India abounds with excavated monuments of art; these are equally found in the centre as well as the sides of the vast peninsula. Throughout the region nature seems to have supplied the first associated inhabitants with excavations, either ready formed or easily converted to the purposes wanted. It therefore appears probable that the originating principal of the building art in India is found in the subterranean dwelling; and as we find constructed edifices so similar in proportion, form, and details to those that are, as it were, quarried out, it is fair to conclude that the former are the type of the latter, which are, consequently, of a later date.

Construction scarcely seems a term applicable to the greater number of works of Indian architecture. It means the raising of a work composed of divers materials, or of pieces joined together to form a mass; hence it cannot be properly applied to an excavated structure. The edifices of India may be divided into two classes, the quarried and constructed; the last are mostly those towers improperly called pagodas. Of the unconstructed class may be ranked the seven large pagodas of Mavalipouram, which consist of large masses of stone more or less engaged to the earth, and contiguous to similar masses. These masses were shaped and sculptured exteriorly in accordance with their general form, partly pyramidally and partly by irregular zones, in the same style as the pyramidal tower of the constructed pagoda. No order is apparent in the respective dispositions of the masses, neither is regularity in the plan and exterior form to be detected. These edifices are extremely small in the interior, being hollowed out of the mass, and remind us of the monolythic temples of Egypt, which were cut out of immense blocks of granite, and, as Herodotus tells us, removed to very considerable distances. In other respects, there was clearly some resemblance between the art of India and Egypt; it is found in the excavations of monuments, and in working large natural masses of stone in their original situation. But to infer from this similarity of taste that there was communication between the two nations, seems too much; and still more hypothetical would it be to infer a resemblance of style in architecture from a similarity of practice; for nothing is more unlike the Egyptian than the Indian style of architecture; and in the end it will be seen that, except in the practice of excavation, there is no similarity at all. The dimensions of the pagodas, as they have been called, compared with those of the Egyptian pyramids, no less than their excavated temples, have been much overrated by travellers. Of the latter, the dimensions are generally but moderate, and the difficulty of their execution could not have been very considerable. If the description that comes to us be correct, the latter are hollowed out from quarries of calcareous stone, and the dimensions are on so moderate a scale, that even the celebrated temple at Elephanta is only 130 feet long, 110 feet wide, and but 14 feet 6 inches high. The operation of hollowing out a cavern of this sort can scarcely be dignified with the name of art; but in the pagoda construction we must admit some display of that which at least approaches it. The pagodas are, in many instances, of considerable height; but to compare them with the pyramids of Egypt is out of the question: these, the only buildings of much height, are pyramidal in general form. Sonnerat, vol. i. p. 217., gives us some idea of them: he says, "Around the most celebrated temples the surrounding walls are thick and much raised. On each side is a gate surmounted by a pyramidal tower, with a curved mass of enormous size. The tower is loaded with figures," &c. &c. If we may trust to the representation of the pagoda of Chillambaram by M. Durocher de la Perigne, given by Caylus in the 31st vol. of the Mémoires de l'Académie, the pyramidal form is therein strongly marked. In it the height of the whole is but 120 feet, and at its base it is but 80 feet wide. The termination is not in a point, but is truncated at a height which makes the plan of its summit about 36 feet wide. The pyramid is unequal sided, the flanks being much narrower than the faces. But the largest of these monuments is that described by Lord Valentia, namely, the pagoda of Tanjore, which he considers the finest specimen of this species of building. This is 200 feet high, placed on a basement of 40 feet in height. The pyramidal mass rises by twelve sets off, or bands, sculptured in various ways. Such samples of masonry, however, required no great display of constructive skill for their execution, either in working or transport of the materials. At Chillambaram, for instance, the pyramidal part is constructed to the height of 30 feet only in masonry, the remainder being of brick. The mass is coated with ornaments of stone and of a species of white cement of the country. As in Egypt, none of the monuments of this country exhibit any trace of the arch: the coverings of the apartments are all horizontal, and the dimensions in all are necessarily limited by the want of that expedient which, in modern architecture, has been the parent of the most stupendous monuments whereof art was capable. The ceilings in Indian architecture are of enormous blocks of stone, laid on the supports wherewith the buildings are constructed, being the simplest and most inartificial mode of contriving a covering to an apartment. It must be apparent to every one, that the art of India was many degrees below that of Egypt. Though, in the last-named country, art was limited by the habits of the people, yet it is equally certain that their knowledge in the use of materials was of a high character, and that their skill in masonry was carried to great perfection.

That which is known to the architect by the term ordonnance, which means, in its most extended sense, the composition of a building and the due arrangement of its several parts, and which the Greeks and Romans practised in their architecture with so much success, is not perceptible in Indian architecture, as far as we are acquainted with it. It seems easy to account for this, for, notwithstanding some of the existing monuments have received the name of palaces, there is little doubt of their being all destined originally for religious purposes. Hence the architects, confined to certain established routines, were not at liberty to exercise their invention and ingenuity; and even had they been so, the system of castes, in perpetuating uniformity of practice, had a tendency to repress them. Again: scarce any system could be conceived less likely to develope talent in ordonnance than the use of subterranean edifices, which admit of no variety of plan, no extent of elevation, nor lead to any of those conceptions, which the taste of the architect generates when he has length, breadth, and materials at his command. In the caves at Ellora, a plan of the Indra Subba whereof is here subjoined, if we examine what



may be called the columns, we find some of them hexagonal, without base, capital, or ornament; some square, with a long cap, like carpentry. The greater number are composed of three parts: a square pedestal, running up more than one half of the total height; a small portion of shaft, if we may so term it, crowned with a capital of strange form, whereof words cannot give any definite idea. The reader who is desirous of acquaintance with the temples at Ellora, may advantageously refer to Daniel's plates of these curious objects. Decoration, in architecture, consists of large and small details, which receive the name of ornaments. The larger parts are columns and similar masses. In the system of Indian decoration there is no trace of what may be called an order; but among the larger masses of decorations for support, sculptured elephants very frequently occur. In one of the temples at Ellora, for instance, there are three masses of building, on the same line, whose bases are sculptured with elephants, seen in face. Lions are also much used as objects for decoration.

From information which Sir C. W. Malet obtained, the works at Ellora were said to be executed about the year 900, by Elloo, the rajah of Ellichpour, who at that period is said to have founded the town: and the late Dr. Heber, bishop of Calcutta, observing that no mention was made of these excavations, even incidentally, in any Sanscrit manuscript, and that the idols were the same as those still worshipped in India, dates them in the 13th century. But all this is conjecture, unsupported by any historical document that entitles it to any weight, and a wide field is open to the traveller and antiquary, in investigating these curious and fantastic monuments, as illustrative of the early history of the art.

Architecture, *Moorish or Saracenic.* When the victories of the Arabians had extended their empire from

Constantinople to the confines of Spain, the magnanimity of their leaders, and the brilliant talents of their caliphs, raised the nation to a pitch of glory and power which exhibited itself in some very extraordinary productions in the architectural art. In Africa and in Spain, where their empire became firmly established, the edifices they erected sufficiently prove with what success they cultivated the arts and sciences. For the notice here given of some of the most extraordinary edifices for which Spain is indebted to its ancient conquerors, we are assisted from the celebrated work by Murphy, published in 1816, to which the reader who seeks further information may refer.

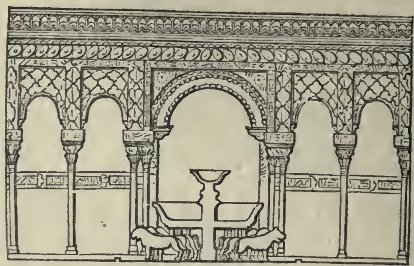
We do not, in the limited space of such an article as this, think it necessary to extend any inquiry into the earliest works of the Saracens, such as the original Mosque of Omar, built in 640. Neither of that nor other of their works (few indeed in number) have we sufficient historical evidence to compare them with the architecture of the period in other countries; but we proceed at once to that period when some of its most distinguishing features were such arches as are here exhibited.

The mosque at Cordova was begun by Abdelrahmen, the second king of Cordova, and finished by his son towards the end of the eighth century. Its plan is a parallelogram of 600 feet by 400, formed by an embattled wall with counterforts also embattled; the height of this wall varies from 35 to 60 feet, and its thickness is 8 feet. This large quadrangular space is divided internally into two parts; viz. a court, 200 feet long by the length of the edifice, and the mosque itself, which is about 400 feet square. The mosque consists of 19 naves, formed by 17 rows of columns, from south to north, and 32 narrower naves, from east to west. Each of these naves is 16 feet wide, from north to south, by 400 feet long; the width of them in the opposite direction is less. Thus the intersection of the naves with each other produce 850 columns, which, added to the 52 columns of the court, form a total of near a thousand columns. Their diameter is about a foot and a half, and their mean height about 15 feet, and they are crowned by capitals of a Corinthian or composite species. These columns, which have neither socle nor base, are surmounted by arches from column to column. The ceilings are of wood painted, each range forming on the outside a small roof, separated from those adjoining by a gutter. One of the most striking effects of the edifice is produced by the beautiful marbles whereof the columns are composed. It seems probable that the larger portion of these columns might have been procured from the Roman ruins in the city; an opinion which is strengthened by their being without bases, or such as ill suited the style of the columns or capitals. In the commencement of the sixteenth century great changes were made in this mosque, for the purpose of converting it into a Christian church; these, it is said, ruined the original effect, but enough is left to indicate what it anciently must have been. It is always considered as one of the earliest Moorish buildings in Spain. The decorations throughout are in stucco, painted of different colours, and occasionally gilt, in imitation of the churches of the lower empire. One cannot doubt that its architects were well acquainted with the Byzantine architecture, in which the walls, the arcades, the pavements, in short all the parts were covered with paintings: and it is clear that the Arabians, who really had invented no architecture of their own, spreading themselves in those countries wherein the arts had been established, were thus led to a trial of imitating the old masters.

The Alhambra, at Granada, is perhaps the most curious and interesting Moorish edifice in Spain. It served the double purpose of palace and fortress, and is situate on the summit of a rock that commands the town. According to travellers who have visited and described this edifice, you may here fancy yourself in a fairy-built dwelling. After passing the principal entrance, you arrive at two oblong courts, one of which is called the court of the lions, and is celebrated in Arabian history. A portion of the section of this court is given below. Round these two courts, on the ground floor, are disposed all the apartments of the palace; those for state look out towards the country; the rest, cooler and more retired, have small openings for light under the interior porticos, the whole of which are decorated with painted stucco, porcelain, and the most valuable marbles.

There is on a neighbouring hill another palace, called the Generaliffe, now in a state of ruin; but its ruins show that it was inferior to the Alhambra neither in size nor splendour. It is precisely in the same taste, and the details are similar, proving that the two edifices are contemporaneous.

Surprising as the works we have just named must be considered we do not discover in them that real grandeur which exists in the works of the Egyptians, the Etrurians, the Grecians, or the Romans. The mode of construction, though sufficiently durable, is not scientific, as respects the working of the materials. Brick was the material



most in use; the masonry, where employed, is covered with a coating of stucco, the painting whereof, in different colours, is a great source of the admiration these buildings excite. In the combinations of the building art in these edifices, there is nothing to surprise, from the supposition of extraordinary means used in their erection. The domes which crown their apartments are neither lofty nor large in diameter, neither do they exhibit great mechanical skill. The Moorish architects seem to have had no notion of raising vaults from lofty piers. In the mosque at Cordova, the span from pier to pier would have been less than 20 feet, which to vault would not have required very extraordinary skill; yet herein we find timber ceilings throughout. The use of orders seems to have been unknown to them; they employed the antique columns which they found ready to their hands, or rude imitations of them, without any apparent acquaintance with the types from which they were derived, their principles or proportions. Hence their columns may be more appropriately termed posts. In the forms of Moorish architecture one does not discover a character of originality arising out of local causes. The Arabians had wandered far from their country, in which they had never cultivated the arts; their architecture was, therefore, necessarily formed upon models which were before them, such as the degenerated Roman and Byzantine. Such elements as these, with the materials which the lower empire afforded, formed their taste and monuments. The form of their arcades, whereof we have given some examples above, is confined to this style of architecture. They may be divided into two classes, both of them vicious in construction, from not affording the necessary resistance to thrust near the abutments. In masonry, failure would follow such forms, if practised on a large scale; but where arches are formed of brick, the large surface of cement used, if it be good and the centres not struck until the cement is set hard, allows great caprice in their forms. If the pleasure—we might almost use the word sensuality—of the eye be the sole object, it cannot be denied that success attended the efforts of the Arabian architects of Spain. The details of their decoration, and the fantasticness of their forms, cannot fail to please the eye; and though they may not satisfy the spectator, they are capable of producing on his mind some of the most seductive charms of which the art is capable. The embroidery and painted draperies of the East appear to have been transposed to their architecture. The variety and profusion with which they used their ornaments, moreover, give their masses the appearance of a congeries of painting, incrustation, mosaic, gilding, and foliage: much, perhaps, of this was induced by the law of their religion, which forbade the representation of animals or the human figure. If taste be not required to produce a reason for the admission of ornament, nothing can be more splendid and brilliant than the effects that resulted from their combinations. It cannot be denied that in this profusion of ornament we find the details beautifully executed, and some of their forms extremely fine; and the mode of piercing domes for light, which they practised by means of star-like formed openings, is attended with an almost magical effect.

Architecture, *Mexican*. From the historian Robertson we collect, that the cities of Mexico, large and populous as they are described, were rather the asylums of men just emerged from barbarism, than the peaceable dwellings of a civilised people. Tlascala, according to its description, nearly resembles that of an Indian village. It was but a heap of low straggling huts; according to the caprice of each proprietor, built of turf and stone, and thatched with reeds, the light being received by a door so low that it could not be entered upright. In Mexico, from its peculiar situation, the disposition of the houses was more orderly, but their structure was equally mean. The Mexican temples, and other public edifices, do not appear to have deserved the high praises which Spanish

authors have bestowed upon them. The great temple of Mexico, the most celebrated in New Spain, as far as can be gathered from the obscure and inadequate descriptions of it, has been represented as a magnificent building, raised to such a height that the ascent to it was by a flight of 114 steps, yet it was but a solid square mass of earth, faced partly with stone. Its base on each side extended 90 feet: it decreased gradually as it advanced in height, terminating at top in a quadrangle of about 30 feet, whereon was placed a shrine of the deity, and two altars on which the victims were sacrificed. All the other celebrated temples of New Spain resembled that of Mexico. The temple of Cholula, which was considered the most sacred in the country, was also the most considerable; yet, according to Torquemada, it was but a solid mound of earth, about a quarter of a league in circuit.

The Spanish historians lead us to suppose that the palace of the emperor and the houses of the nobles exhibited some elegance of design and convenient arrangement: we have, however, no vestiges of these remaining, and, from the mode in which Cortes conducted the siege of Mexico, it seems likely that all the monuments of any importance were destroyed. Still, as at the period when Robertson wrote his history only two centuries and a half had elapsed, it seems impossible that in so short a time edifices of importance should have left no trace of their existence.

The great hillock at Cholula, to which the Spaniards have given the name of temple, is without any steps to ascend it, and without any appearance of stone. Perhaps it has never been more than a natural eminence of the ground. In several accounts, though under different names of places, we find descriptions of monuments pyramidal, as well as in steps, of which the ruins are sufficient to furnish a clue to the whole design. The attempt to restore them in drawing was made in 1804, and published at Rome by D. Pietro Marquez, entitled "Due Antichi Monumenti di Architettura." His restoration was founded, we believe, on descriptions published in the Literary Gazette of Mexico, in 1785 and 1791, by D. Gius. Ant. Abzate. The first monument is at a place called Papantla. Its form is pyramidal, (that is, in general effect,) being built in steps or stories, of six ranks, one above the other. The lower step is 100 feet long, on the four faces. The other dimensions of the steps are not given, but each had in its height a certain number of square niches, each 3 feet every way; the lowest contained 24 on every side, the second 20, the third 16, the fourth 12, the fifth 10, and the sixth 8. It is presumed there was a seventh step, which had 6 of these niches on every side. Upon one of the faces of this pyramid there were smaller steps, serving as a staircase to mount to the top, whereon, it is supposed, there was a small chapel enclosing the idols to which the sacrifices were made. The author (Marquez) above mentioned gathered from the same documents some ideas upon another Mexican monument, if in architecture may be so called a hill surrounded by five or six enclosures of stone, whose object was to retain the earth in its place. This also terminates by a platform at top, which is supposed to have been occupied by a small temple, after the manner of the country. Some writers have thought this last was merely a fortification, but it seems more probable that it was a religious edifice, inasmuch as the basement of it is sculptured with figures supposed to be the hieroglyphics of the country. The name (Xochicalco) of this hill, interpreted by those who possess a knowledge of the Mexican language, bears out the conjecture that it was used for the last named purpose.

Architecture, *Roman*. It can scarcely be said that the Romans had an architecture peculiar to themselves. That which we understand by the name is a modification, some call it a debasement (we disagree with them), of the architecture of the Grecians. We are ready to admit that the Romans gave to their art the lasciviousness of the courtesan, whilst the Greeks preserved in theirs the modest demeanour of the staid matron; but our senses may be charmed by the one, though the other may make a stronger appeal to the understanding. In strictness, Roman and Grecian architecture are identical. Wherever the Greeks penetrated, their genius, not less than their arms, extended and founded their influence. The religion, the language, the habits, and the arts of the Greeks, appear to have been carried into Italy at a period of very high antiquity. Numerous colonies of that nation established themselves on the shores of that country, and even in the interior of the peninsula, where they erected cities long before the existence of Rome. Italy, as far as we can trace, had no original arts of its own, nor can any thing be found in it whose origin was not Grecian. Hence, as has been observed, there is, strictly, no such thing as Roman architecture. But as every nation which cultivates the arts, impresses them with a character peculiar to itself, so when we speak of Roman architecture, we mean that peculiar character with which Greek art was invested under the Roman empire,—that character which was manifest in a greater exuberance of ornament in all the parts of the orders, and which changed the sections of the mouldings of an order from profiles formed by the sections of a cone, to those formed by the horizontal sections of a cylinder. An intercourse of very ancient date existed between Etruria and Greece; in the former of which, at the period in question, the language and mythology of Greece prevailed to a considerable extent. From what is known on this subject, we may safely state that Etrurian architecture was identical with that of Greece. History tells that Rome, from its origin, borrowed from Etruria artists to execute their great works, though, afterwards, the city possessed a large number of native architects, which was not the case with the professors of the other arts. That the Romans at this period were not barbarous and ignorant of the arts, more than one memorial of their skill in architecture still attests. Livy records a circus, traced by Tarquin, between the Aventine and Palatine hills, for the celebration of feasts and games to commemorate the victory over the Latins. Tarquinius Superbus soon afterwards encompassed this circus with covered porticos. This was at the epoch of the construction of the great sewer or cloaca. Perhaps in no age were two more splendid undertakings carried on at the same time. This Tarquin, as Dionysius Halicarnassensis asserts, ornamented the Forum, and had centred in it all that could tend to its beauty as well as to its utility. The first Tarquin was a native of the city of Tarquinium in Etruria, and brought to Rome that taste for grandeur and solidity which were the distinguishing features of the arts in the country he had left. He constructed the immense walls of the city in regular masonry, and laid the foundations of the temple of Jupiter Capitolinus, which, in levelling the hill on which it stood, was attended with prodigious labour and expense. The temple mentioned, according to Tacitus, was continued by Servius Tullius and Tarquinius Superbus, the latter engaging workmen from Etruria; but it was not finished till after the expulsion of the kings. Such was its magnificence, says Tacitus, that all the victories of the Romans added to its wealth and decoration more than to its extent. His words are, "Horatius Pulvillus dedicavit, eâ magnificentiâ, quam immensæ postea populi Romani opes ornarent potius, quam augerent." The description of it by Dionysius brings to mind the Grecian temple, with its two interior ranks of columns, its peristyle and pediment, eulogised by Cicero. It was twice destroyed, and twice rebuilt, on the same foundations. These notices suffice to show that the Romans at an early period were inferior to no nation in those matters of architecture which were necessary and useful to a people. Such was the opinion of Strabo, who adds, that in some respects, such as paving their great roads, constructing aqueducts and sewers, the Romans far excelled the Greeks. Usefulness in their enterprises, and solidity in carrying them into execution, were the characteristics of the art among the Romans at a period when magnificence of a high degree was confined to the temple.

The necessary materials are wanting to enable us to follow up historically the taste of the art during the ages of the republic. There is scarcely the vestige of a ruin of the period; it is, however, easy to form, either from the political state of the times, or from the encouragement given to the other arts, and especially to literature, some idea of the extent to which the architecture of the Romans flourished. The conquest of Greece by the Romans produced to their city not only an importation of works of art, but the artists themselves, who, be it observed, can be created only where opulence reigns. In architecture, however, the Romans at this time had erected monuments of such dimensions as were beyond the means of the little and separated states of Greece. The new state of things brought to its aid all that it needed. The great use which at this period was made of the Corinthian order, is one of the proofs of the public and private wealth. From the time of Augustus we see the extent to which richness of detail was carried. A small portion of the Baths of Agrippa, known to us under the name of the Pantheon, one of the most splendid examples of the art, enables us to appreciate the art of this period, though now despoiled of the bronzes of its pediment, its gilt caissons, and the profusion of sculptures that adorned it. In the time of Augustus, Rome was not only the capital of the world, but the world itself; it possessed within itself all the food that was necessary for the nourishment of the art. Private individuals in the city possessed the wealth of kings, military glory created a necessity for monuments, and the amusements of the theatre, the races and fights of the circus and amphitheatre, required accommodation for such multitudes of spectators, that art expanded from the calls to which it was subject. Rome now began to raise monuments of a description unknown to the Grecians—triumphal arches, baths as large as cities, immense porticos, amphitheatres, and naumachia. The marbles of all the quarries of the then known world were almost exhausted in supplies, and even Egypt furnished the city

with means of adding to the general magnificence. Applied to such new species of edifices, it would have been indeed surprising if architecture had preserved its original Greek purity. It was the medium for satisfying a vanity which knew no bounds, and was ultimately obliged to gain its end more by effect than purity, by richness and exuberance of ornament rather than by harmony, and by grandeur of lines rather than by beauty of forms. Architecture was at all periods a favourite art among the Romans. Not a single name of a Roman sculptor has reached us, and Pliny mentions only two or three painters. From Vitruvius we learn, that before his time several had written on the art. The names of Fussitius, Terentius Varro, Publius Septimius, Cossutius, and C. Mutius are mentioned by him.

The luxury in art induced by the sculptor, aided the number of different combinations in the Corinthian capital, which we have above stated to have been a favourite with the Romans; this was carried to an excess which in the end produced a new order, known by the name of the composite. Thus, Roman architecture having, says Quatremère de Quincy, exhausted all the resources of richness guided by taste in the use of ornaments, throws aside all sobriety, sacrifices the whole to details and accessaries, covers all parts of the surface without distinction, loads the different members with ornaments and sculptures, like a person who, to decorate a piece of cloth, covers it entirely with embroidery.

We close this article with a few observations on the Doric order. This, in Greece itself, at the time of her subjugation, had begun to be affected by change. It had lost much of the primitive simplicity of its character and the severity of its principles. The various wants in edifices less simple in plan, a taste for elegance and richness which was found in the other two orders, contributed to diminish the severity of its forms and profiles. Thus, in the portico of Augustus at Athens it was strangely changed in appearance. In Rome it was adopted with proportions still more slender, and an aspect infinitely less severe. (For remarks on English Architecture, *see* the word ENGLISH.)

A'RCHITRAVE. (Gr. ἀρχειν, *to govern*, and Lat. trabs, *a beam.*) In Architecture, the lower of the three members of the entablature of an order, being, as its name imports, the chief beam that is employed, and resting immediately on the columns. Its origin is given under the article ARCHITECTURE. A French writer has called it the foundation of the head of an edifice. The architrave sometimes receives the name Epistylium, from the Greek words ἐπι, *upon*, and στυλος, *column*.

A'RCHIVES. The repositories of the public records of a state or community: sometimes the records themselves are so called. The word is supposed to be derived from the Greek ἀρχεια, used for public registers by Josephus.

The following table presents a summary of the principal metropolitan repositories of English archives, and the character of their contents. It is extracted from the Law Magazine, No. 35. and is professedly compiled from the information furnished by the Record Commission.

Name of Repository.	Situation.	Species of Record.
1. Tower	Thames Street	Chancery & Parliamentary
2. Chapter House	Poet's Corner, Westminster.	King's Bench, Common Pleas, Parliamentary, Miscellaneous
3. Duchy of Lancaster	Waterloo Bridge	Relating to the Duchy
4. Duchy of Cornwall	Somerset House	Relating to the Duchy
5. Roll's Chapel	Chancery Lane	Chancery & Parliamentary
6. Common Pleas	Carlton Ride Stables	Belonging to the Court
7. King's Bench	Rolls' House, Chancery-lane	Belonging to the Court
8. King's Remembrancer's Record	Carlton Ride Stables, Temple, Tower of Westminster Hall	Chiefly Exchequer
9. Augmentation Office.	Palace Yard, Westminster	Ecclesiastical Record respecting dissolution of Monasteries
10. Pipe Office	Somerset House	Exchequer Records
11. Lord Treasurer's Remembrancer's Office	Somerset House	The same
12. Land Revenue	Carlton Ride, and Spring Gardens	Its own department, and Exchequer Records, &c.
13. First Fruits	Temple	Its own department.
14. Exchequer of Pleas	Lincoln's Inn	Exchequer.

A'RCHIVOLT. (Lat. arcus volutus, *a turned arch.*) In Architecture, the ornamented band of mouldings round the voussoirs or arch stones of an arch, which terminates horizontally upon the impost. The archivolt is decorated analogously with the architrave, which it may in arcades be said to represent.

A'RCHON. (Gr. ἀρχων, *ruler.*) The title of the chief magistrate of Athens. The office was originally instituted after the death of Codrus, the last king of Athens, and was vested in one person who enjoyed it for life, and was succeeded by his son. Its duties were those of a limited monarchy, accountable to the assembly of the people; its duration was afterwards limited to ten, six, and, finally, one year, when its functions were divided among nine persons, taken at first by suffrage, and afterwards by lot, from the nobles. One was chief among them, and was called Eponymus, or, naming Archon, because the year was distinguished by his name. The second, or king Archon, exercised the functions of high priest. The third, or Polemarch (polemarchos,) was originally the chief military commander. The other six were called Thesmothetæ, or setters forth of the law; they presided as judges in the courts, and the six formed a tribunal which had a peculiar jurisdiction. The nine together formed the council of state, on which the whole administration rested; but this was transferred by Solon to the senate. The exclusive right of the nobles to this office was taken away by the measures of Cleisthenes, who threw it open to the people at large. *See* especially *Boeckh's Public Economy of Athens*.

A'RCTIC. (Gr. ἀρκτος, *the bear.*) An epithet given to that part of the heavens, in which are situated the constellations of the Great and the Little Bear. *Arctic Pole*, the north pole of the heavens, or the northern extremity of the axis of the diurnal motion. *Arctic Circle*, in geography, denotes a small circle of the sphere parallel to the equator, and 23½ degrees from the north pole. At this latitude, the sun, at the summer solstice, comes exactly to the horizon at midnight, without descending below it. The corresponding circle in the southern hemisphere is called the *Antarctic*. The arctic and antarctic circles separate the frigid from the temperate zones.

A'RCTOMYS. (Gr. ἀρκτος, *bear*, μυς, *mouse.*) The name of the subgenus of *Rodentia*, or gnawers, including the marmot.

ARCTU'RUS. A star of the first magnitude in the constellation of Bootes, designated in the catalogues as α Bootes. It has a sensible proper motion.

A'RCUATE. (Lat. arcus, *a bow.*) A part of an animal so called which is linear and bent like a bow.

ARCUA'TION. (Lat. arcus, *a bow.*) An obsolete term for the mode of propagating trees by layers, the shoots being bent.

A'RDEA. The name of a Linnæan genus of *Grallæ*, or wading birds, characterised by a straight, sharp, long, subcompressed bill, with a furrow extending on each side, from the nostrils to the apex of the bill. The genus was subdivided by Linnæus into the *Cristatæ*, corresponding to the modern genus *Anthropoides;* the *Grues*, or cranes; the *Ciconiæ*, or storks; and the *Ardeæ*, or herons; which latter have been subsequently subdivided into *Ardeæ*, or herons proper; *Nycticoraces*, or night-herons; and *Botauri*, or bitterns.

ARDISIA'CEÆ. (Ardisia, *one of the genera.*) Exogens, which might, without much inaccuracy, be termed woody primulaceous plants. They form herbs and trees in warm countries, and have a succulent fruit; but they really differ in scarcely any positive point of structure from primula and its co-ordinates. (*See* MYRSINACEÆ.)

A'RE. *See* A LA MI RE.

A'REÆ. In Entomology, the larger longitudinal species into which the wing may be divided: they are termed cretal, intermediate, and anal, according to their relative position.

ARE'CA. (Areec, *the Malabar name.*) An East Indian palm tree, whose nuts are folded in the leaf of the piper betel, and, mixed with a little lime, are chewed by the natives of the country bordering on the Indian Archipelago, as a stimulating narcotic.

ARE'NA. A Latin word signifying, in its original meaning, sand, but applied in a secondary sense to that part of the amphitheatre in which the gladiators fought, which was covered with sand. The word is sometimes applied to the whole amphitheatre.

ARENA'CEOUS. (Lat. arena, *sand.*) Sandy.

ARENA'RIA. (Lat. arena, *sand.*) A genus of wading birds, wanting the hinder toe: of this genus there is but one British species — the Sanderling.

ARENA'RIOUS SOIL. (Lat. arena, *sand.*) In Agr. and Hort., soil in which sand is the prevailing ingredient.

ARENA'TION. (Lat. arena, *sand.*) The cure of diseases by sprinkling hot sand upon the body.

ARE'OLA. (Dim. of *area.*) The ring or margin which surrounds the pustule of small and cow pox.

ARE'OLÆ, in Entomology, are smaller spaces into which the wing is divided by the nervures: they are termed vasal, middle, and apical, according to their relative position.

ARE'OLATE. In Entomology, divided into small spaces, or areolations.

AREOLATE. In Botany, in composite plants, when the florets are placed so completely upon the surface of the

receptacle, that many a pentagonal area, or space, is left when the ovaries drop off.

AREOLA'TION (Lat. *area*) means any small space, distinctly bounded by something different in colour, texture, &c. The spaces of parenchyma, which in leaves are bounded by veins, are areolations.

AREO'METER. (Gr. ἀραιος, *rare*, and μετρον, *measure*.) An instrument for measuring the density or specific gravity of fluids. (*See* HYDROMETER.)

AREO'METRY. The science of measuring the density or specific gravity of fluids.

AREO'PAGUS. The chief court of judicature at Athens: so called because it met in a hall on an eminence, called the hill of Mars (Ἀρειος παγος.) This court, which was of very early origin, was raised to the high character it afterwards enjoyed, by Solon, who appointed that it should consist of the archons who had undergone, with credit, the scrutiny they were subject to at the expiration of their office. The areopagus had cognizance of capital crimes, and from it was no appeal to the people, whose decisions it was sometimes known to annul. It controlled all issues from the public treasury, and exercised a censorship over the citizens. Its powers were much reduced by the measures of Pericles and his partizans. On the subject of this celebrated institution, our best ancient authority is the *Oratio Areopagitica* of Socrates. See also Meursius, *De Areopago*; Du Canaye, *Recherches sur l'A.*, in the *Mém. de l'Acad. Des Inscr.*, *&c.* vol. vii. p. 174.: and Petitus, *Ad Leges Atticas*. See also Boeckh's excellent work on Athens and her Institutions.

A'RGEL. The Egyptian name of the leaves of the *Cynanchum oleafolium*, which are mixed with senna leaves.

A'RGENT, in Heraldry. (French, argent, *silver*.) One of the metals employed in blazonry: it is equivalent to pearl among precious stones, diamond among planets. In engraving it is represented by a plain surface.

ARGENTI'NA. A Linnæan genus of abdominal fishes, belonging to the salmon family; characterised by a small mouth, without maxillary teeth; the tongue armed with curved teeth; and a transverse row of small teeth on the vomer; banchiostegal rays, six. The argentines rank in the order *Malacopterygia*, or soft-finned fishes of Cuvier. The name is derived from the silvery glistening appearance in the scales of these fishes.

A'RGENTINE. In Mineralogy, nacreous carbonate of lime, so called from its silvery lustre.

ARGILLA'CEOUS SOIL. (Lat. argilla, *clay*.) Soil in which clay is the prevailing earthy ingredient.

ARGOL. The tartar of wine.

A'RGONAUT, ARGONAUTA. Applied by Linnæus, in the singular number, to the testaceous cephalopod, designated by Aristotle and the ancients, nautilus, and commonly called at the present day the paper nautilus, from the fragile nature of the boat-like shell in which the inhabiting cephalopod occasionally floats on the still seas of the warmer latitudes. Many modern naturalists limit the application of the term argonauta to the shell, supposing that its true constructor is yet to be discovered, and that the cephalopod which has hitherto been exclusively found in it, is a parasite. (*See* OCYTHOË.)

A'RGONAUTS. The name given to the chieftains "who accompanied Jason in the ship Argo on his fabled expedition" to Colchis, after the golden fleece of Phryxus. The original facts on which this mythological story is founded cannot now be recalled; but it is generally supposed to represent the result of some bold commercial expedition that overstepped the previous discoveries of its age, or more probably still, the series of enterprises by which "Greek maritime knowledge was extended to the furthest shores of the Euxine." We have a poem on the subject, which falsely goes under the name of Orpheus, who is said to have been one of the Argonauts himself, and an epic by Apollonius Rhodius, a Greek poet of Alexandria, and likewise one in Latin, by Valerius Flaccus, who flourished in the age of Vespasian.

A'RGUMENT. In Astronomy, denotes the angle or quantity on which a series of numbers in a table depends. For example, suppose a table were formed showing the amount of horizontal refraction at every degree, &c., of altitude; then the altitude would be termed the argument of the refraction; and the table is said to be entered with the argument.

ARGUMENT. In Logic, an expression in which, from something laid down as granted, (*i. e.* the premises,) something else (*i. e.* the conclusion,) is to be deduced. In ordinary discourse, argument is very often used for the premises alone, in contradistinction to the conclusion; *e. g.* "the conclusion which this argument is intended to establish, is, &c. &c." This word is also sometimes employed to denote what is, strictly speaking, a *course* or *series* of arguments: it is in this sense that we speak of "Warburton's argument to prove the divine legation of Moses." The word argument is frequently used to express what may be properly called a disputation: *i. e.* two trains of argument opposed to each other, as when it is said that A and B had a long argument on any subject, and that A had the best of the argument. (Vide *Whately's Logic*, p. 300.)

A'RIANS. The followers of the theological opinions of Arius, a presbyter of the church of Alexandria in the fourth century, who denied the equality of the Father and Son, and is generally considered as the author of a system which continued, under various modifications, to exercise the most extensive influence upon the Christian world of any heresy of ancient times. It was in the year 319, that these views were first promulgated at a meeting of the clergy of Alexandria; and their author, after some delay, excommunicated by the patriarch Alexander. The progress, however, which the opinions continued to make, excited, after a few years, the notice of the emperor Constantine, who addressed a letter to Alexander and Arius jointly, in which he attempted to attain the object for which on other occasions he resorted to more violent methods, that of reconciling the conflicting parties upon whatever basis, and securing harmony at all events. At the earnest desire, however, of the orthodox party at Alexandria, he convened the general council of Nicæa, which assembled in the year 325, and proceeded to institute a full investigation into the matter in dispute. On this occasion the Nicene creed was drawn up, in which the clause which principally affects this subject is the assertion of the consubstantiality of the Son with the Father, or the Omoousion. This the Arians would not concede. A middle party arose under Eusebius of Nicomedia, who proposed, but without effect, the term Omoiousios, asserting, not the identity, but the similarity of substance. This, which is generally denominated the Semi-arian scheme, satisfied neither the Catholics nor the Arians, who from their rejection of it acquired the title of Anomoioi. The Catholics triumphed, and their opponents submitted to the decree of the emperor which required them to acknowledge the creed propounded for their acceptance. From this time, according to some writers, the Eusebians became a mere political party, who endeavoured to preserve the favour of the prince, for which they had already made the greatest of sacrifices, by a repetition of similar unworthy arts. At this period another Eusebius, the courtly bishop of Cæsarea, and celebrated historian of the Christian church, became one of the leaders of this branch of Arianism. His talents and ingenuity are represented as being of singular service to the cause of the heretics, by inducing the emperor, after some delay, to command the restoration of Arius to the church of Alexandria, and the banishment of Athanasius. A day was appointed, upon which Alexander, the aged bishop, should admit the still suspected heretic to the holy communion: his protestations of orthodoxy were such as to satisfy the prelate that God only could discover his real sentiments, and he solemnly declared that in His hands he left the matter. In the midst of the fears and scruples of the one party, and the anticipated triumph of the other, the proceeding was suddenly terminated by the death of Arius: a deliverance of the church, in which the Catholics discovered a signal interposition of God, but which the heretics confidently ascribed to assassination by poison.

Under Constantius, the successor of Constantine, in the East, the Arian party was taken into favour, and the orthodox persecuted and proscribed: and when on the death of Constans, the whole empire fell into his single hands, the cause of heresy began to flourish in the West also, and the "whole world," says St. Jerome, "groaned to find itself Arian." It was at this period, also, that many northern nations, who were just preparing to pour themselves upon the western empire, were converted to the Christian faith, in which they were instructed, according to the Arian interpretation. This circumstance contributed materially to the permanence of these opinions; for after the orthodox emperor Theodosius had re-established the doctrine of the Nicene creed throughout his dominions, the West was subjected to a second inundation of heresy in the preceding century. The conversion of Clovis to the Catholic faith at the end of the fifth, and of Theodelinda, queen of the Lombards, in the sixth century, combined with the successes of the generals of Justinian, in Italy and Africa, restored the orthodox opinions throughout the greater part of these regions; and from that period Arianism dwindled away, and all traces of it seem to have been lost for many centuries.

In modern times these opinions have been revived. The inferiority of the Son to the Father was proclaimed by Servetus, in 1531: and in Geneva, the very place in which he suffered death, these opinions took root, and have since become very prevalent among the disciples of the church which Calvin founded. The immediate followers of Servetus removed, upon his death, to Poland. In England, the principal revivers of Arianism, were Whiston and Samuel Clarke, who flourished at the be-

ginning of the 18th century. Their doctrines were embraced by great numbers of the Presbyterian and Independent preachers, and gave rise to a great deal of controversy among the members of those communities, and of the church also. It is remarkable that the congregations which in modern times have embraced any form of Arianism, whether at Geneva, in Poland, or in our own country, have in almost all cases degenerated into Unitarianism. At the present day, there exist few, if any, churches of professed Arians.

It should be remarked, that the term Arian, which is vulgarly attributed to those who conceive of the second and third persons, that though inferior to the first, they are, nevertheless, divine, admits of many distinctions and qualifications. Questions arise among sects generally denominated Arian, 1st, As to the similarity of substance between the Father and Son: 2d, As to the existence of the Son; whether he was created before the world;—whether that creation was from eternity: 3d, As to the relation of the Son and Spirit, concerning whose rank among the Divine personages there are many conflicting opinions. Dr. Clarke, though generally considered to hold Arian sentiments, professed himself a believer in the Trinity, and continued a member of the established church. He distinguished the Son from the Father, considering the latter as the primary author of all good, to whom all honour and worship is due: the power which was original in the Father being derivative in the Son, who derives also from him his Divinity and other attributes. The Holy Spirit, he considered to hold a similar subordination to the Son. When the question, whether the Father can annihilate the Son, was propounded to Dr. Clarke, he confessed that he had not reflected upon this imputed consequence of his scheme, and declined to give any answer.

ARICI'NA. An alkaloid discovered in 1829, by Pelletier and Coriol, in a bark from Arica, resembling a species of chinchona.

A'RIEL. Arilla (*in low Latin*), *a piece of red cloth.* A membrane, either fleshy or otherwise, originating from the placenta, and growing on a seed either partially or entirely. Instances of it occur in the nutmeg, where it constitutes mace; and in the Euonymus Europæus, where it is a red succulent membrane. It is remarkable that this part, the use of which is unknown, never appears till after the young seed is fertilised.

A'RIES. (Lat. *the Ram.*) The first constellation of the ancient zodiac. Aries also denotes the first sign or the first 30 degrees of the zodiac; the first point of Aries being the point in which the equator intersects the ecliptic, and from which the longitudes are reckoned. In ancient times the signs and constellations of the zodiac coincided; but owing to the precession of the equinoxes, the twelve signs go backward among the constellations, at the rate of about 50″ annually, and the first point of Aries is now situate in the constellation Pisces.

ARIES. In ancient Military Science, the Latin name of the battering ram, an instrument with an iron head used to batter and beat down the walls of besieged places.

ARIOSO. *See* LEGATO.

ARISTO'CRACY. (Gr. ἄριστος, *the best*, and κράτειν, *to govern.*) According to the acceptation in which the word is used by ancient writers, a government in which all the *best* citizens of the state, *i.e.* those excelling either in hereditary distinction or in wealth, ruled their fellow-citizens. When the power was in the hands of a small class of these, who had acquired it by chance or usurpation, such a government was said to be an oligarchy. Thus aristocracy is enumerated by Aristotle among the distinct forms of government; oligarchy is only mentioned as a perversion of aristocracy: and the distinction as taken by him is, that in an aristocracy the governors rule for the public good, and in an oligarchy for their own. In modern times, those governments have usually been termed aristocratic in which a small privileged class of noble or wealthy persons either governed absolutely, or shared the government in various proportions with the sovereign or with the people. Thus the Republic of Venice presented the purest example of an aristocracy among the older governments of Europe: while the government of the United Provinces, before the French Revolution, might also be cited as an instance of an aristocratic commonwealth; and Great Britain of a monarchy tempered by aristocracy. In a stricter sense, however, the word has been used by modern speculative politicians to signify any government in which "a minority of adult males" constitute the ruling class. In this sense, the government of France, that of England both in respect of the House of Commons and of the House of Lords, and, in short, almost every state in which a census is adopted as the qualification of those who elect representatives in the national assembly, must be cited as aristocratic. The word aristocracy is also frequently used to signify a class of persons in the state: the wealthy and noble classes in a body, or the latter class by itself.

ARISTOLO'CHIA. (Gr. ἄριστος, *best*, and λοχεια, *childbirth.*) A genus of exogenous plants, usually having twining stems and one-sided bent, yellow or purple variegated flowers, the odour of which is often very offensive. They are reputed to be powerful stimulants and aromatics. One species, but not a twining one, is occasionally met with wild in England (A. clematitis, common birthwort): a few are natives of the South of Europe, but the principal part of the genus is tropical.

ARI'STOLO'CHIA'CEÆ. The natural order of which Aristolochia is the type. Asarum (*see* ASARABACCA) is the only other common genus associated with Aristolochia; but there are several tropical forms. The wood of this order is remarkable for growing without forming concentric zones, although undoubtedly exogenous.

ARISTOTE'LIAN PHILOSOPHY. In attempting to give an account of the doctrines of Aristotle of Stagira, we feel embarrassed by peculiar difficulties. The prejudices under which, until lately, the name of this philosopher has laboured, and still, perhaps, continues in a great measure to labour, would seem to render a more than usually detailed account of his writings necessary, in order to justify what, in the view we shall take of their nature and value, may contradict the ordinary opinion. At the same time, there is perhaps no ancient philosopher, the full comprehension of whose system requires so extensive a knowledge of the works of his predecessors in scientific research, and so careful a collation of detached passages in his own writings, which are composed for the most part in a fragmentary and unmethodical manner, and an obscure and concise diction. The latter difficulty will be the more apparent, when we state the now unanimous opinion of the learned, that the works of Aristotle which remain to us are entirely of the *esoteric* or *acromatic* class, intended, not for publication, but to serve as notes to the oral lectures which he delivered to the more instructed of his pupils. It requires no more than a cursory glance at the titles and the bulk of Aristotle's writings, to be convinced of the comprehensiveness of his views, and the daringness of his design. He divides the whole circle of knowledge into three great provinces, Metaphysics, or the Philosophia prima, including, as its instrument, Logic; Physics, or the Second Philosophy, under which term, in addition to the sciences ordinarily falling under that denomination, he embraces a great portion of the philosophy of the human mind, as the phenomena of sensation, memory, and fancy; and, thirdly, Ethics, or the science which treats of the conduct and duties of man, regarded both as an individual and as a citizen. His Logic is contained in his Categories, his treatise on Interpretation or the Nature of Propositions, his former and latter Analytics, and his eight books of Topics; to which may be added his work on the exposure of Sophisms. These form together what has been called the Organism of Aristotle; and seem intended as a preparatory discipline to the study of his Metaphysics. (See *Arist. Metaph.* iv. 3.) The common opinion, which attributes to Aristotle the discovery of the science of Logic, is, we doubt not, substantially correct. The flippant objection of Locke, that this notion would represent God as having made men mere animals, and having left it to Aristotle to make them rational, hardly needs a serious refutation. Natural philosophers might with equal justice be accused of asserting, that Sir Isaac Newton changed the motion of the heavenly bodies, or that Locke himself created the human understanding. The logic of Aristotle is, what it professes to be, an enumeration of the leading classes, or genera, to which all our notions may be referred; an account of the various methods by which we arrive at general propositions, and reason from these when formed; and a body of rules for the conduct of the understanding in going through these processes. (*See* LOGIC, CATEGORY, &c.) Metaphysics is the science of being, as such; and herein is distinguished from physics, which considers only the modifications of being, and the changes to which they are subject. Each of the physical sciences has its own fundamental axioms, the truth of which it is compelled to assume: it is the province of metaphysics to verify these assumptions, and to discover their unity and connection. Aristotle's metaphysical system, though it may be said to owe its origin and many of its peculiarities to that of his great predecessor, Plato, yet deviates from it in many important respects. Both the one and the other admit the existence of a faculty, the sphere of which transcends the objects of sense: they differ as to the method by which this faculty is to arrive at its determinations. Plato doubtless conceived, that in virtue of the necessary connection in which all conceptions stand to each other, we are able, so soon as we have awakened one idea in our consciousness, to arrive at the knowledge of all the rest. Aristotle, on the contrary, conceived all deductive science to be illusive which does not rest, for the truth of its fundamental principles, on a previous induction from particulars. Agreeably to this conviction, he begins his Ontological speculations with the consideration of the individual, as it presents itself in the world of sense. To the production of each separate existence, four causes are

necessary: the material cause, the formal, the final, and the moving cause. The three latter, he seems to admit, are substantially identical, inasmuch as in Nature the end of a thing is that very thing itself in its completeness: while the moving cause may be conceived as the type pre-existing in the mind of the artificer, which is the same with the form which he communicates to the material. We should greatly misconceive Aristotle's meaning, if, as has sometimes been done, we identified his forms of things with their outward figure, or even with the notion of them apprehended by the understanding. The form of a thing may be differently expressed, as the law of its being, the principle of life within it, which animates and gives an individual existence to the matter; which, on the other hand, without its presence, would remain a mere blank potentiality, destitute of all qualities, and therefore unintelligible and imperceptible. This distinction between matter and form re-appears, under different names, in various portions of the Aristotelian philosophy, and is with him a solution of most of the difficulties in ontology and physics. He conceives it to be the only mode of explaining the possibility of a thing coming into existence, the difficulty of comprehending which had led the electic philosophers to deny any reality to outward phenomena. He himself conceives the universe to be eternal. With Plato, however, he strenuously asserts the existence of reason, as something immutable and universal: co-eternal with but unaffected by the shifting phenomena of the world. He differs from that philosopher, in making the universal reason identical with God, instead of being, with its correlative being, a creation of the Divine energy.

Of Aristotle's strictly physical researches we shall say little. He does not himself seem to conceive that great certainty can be attained in this department of human science. When, however, we remember, that his History of Animals has received very high praise from no less a naturalist than Cuvier, and when we reflect that this was perhaps the only branch of natural science in which he was furnished with experimental data, we shall be inclined to attribute the errors and deficiences of his physical theories rather to the deficiencies of the Greeks in the necessary mechanical apparatus, than to any disqualification in the philosopher himself. In his treatises on the Soul, on Memory and Recollection, and on the Nature of Dreams, he has earned the perhaps still higher praise of having created the science of Psychology, and of having discovered the guiding clue to the explanation of our mental phenomena, in the principle of association.

The third great division of the Aristotelian philosophy, that which regards the relations of man as a "social and political animal," is comprised in the Politics, the Œconomics, the Nicomachean and Eudemian Ethics, and those books entitled the Magna Moralia. In the true spirit of an ancient Greek, Aristotle regards the science of ethics as most intimately connected with that of politics. He repeatedly expresses his aversion from all speculations on merely ideal perfection; and his conviction that the practicable, under the existing circumstances of humanity, is the true object of ethical enquiry. Among the most influential of these circumstances on the conduct of an individual, is the constitution of the state to which he may belong; in the spirit, and according to the maxims of which he must act, if he would earn the praise of a good citizen. Not indeed that a good citizen and a good man are necessarily identical terms: they can only become so in the case of one who is a dutiful member of a rightly constituted commonwealth. The question necessarily arises, "How is this perfect form of polity to be determined?" The answer is, that form of government is the best, which affords scope for the developement of the best part of our nature; in other words, which produces the best men. Out of this circle, Aristotle cannot be said to have fairly extricated himself. He has in some measure approximated to a definite rule of morality in the doctrine, that every virtue lies between two opposite excesses. It must however be confessed, that a certain degree of vagueness prevails in his ethical speculations: a vagueness of which he was himself conscious, and apparently despaired of satisfactorily removing. Perhaps the most valuable part of his moral writings, is that in which he discusses the much vexed question of the relation of happiness to morality. Pleasure, he determines, can never be taken as a measure of actions, inasmuch as it is the uniform concomitant of all natural action whatsoever. (*Eth. Nic.* l. x.) His politics comprise a most careful review of the most celebrated Grecian constitutions, and a generalization of the leading possible forms of government, with their various merits and defects, built on a careful induction from the great mass of varied facts and instances with which the history of his country supplied him. They are consequently invaluable, alike to the curious in Grecian history, and to the political theorist; and traces of their effects are sufficiently visible in the writings of perhaps all who have arrived at eminence in the latter department.

The best edition of Aristotle's complete works is that of Bekker, 3 vols. 4to. Berlin, 1831. Of the Ethics, that of Michelet, with a commentary, 2 vols. 8vo. Berlin, 1835. Of the Politics, those of Schneider and Göttling. Of the Treatise de Animâ, with copious notes, that of Trendelenburg. Numerous editions of the Rhetoric have been published in Oxford. Of his Ancient Commentators, the best are Ammonius, Alexander Aphrodisiensis, Simplicius, and Thomas Aquinas.

ARI'THMETIC. (Gr. ἀϱιθμος, *number.*) The science of numbers, or that part of mathematics which is concerned with the properties of numbers. The elementary operations of arithmetic, being necessary in transacting the ordinary affairs of life, are perhaps as commonly known as the art of reading and writing, and therefore require no explanation; the principles, however, on which they depend are of a very general and highly refined nature.

Every number, according to the definition of Newton, is, properly speaking, only a ratio, or relation. In order to explain this, it may be remarked, that every magnitude which we compare with another magnitude is either equal, or greater, or less, and, consequently, has a certain relation to that with which it is compared; that is to say, it either contains it or is contained in it, in a certain manner. This relation, or manner of containing or being contained, is what we call number: thus the number 3 expresses the ratio which one magnitude has to another smaller than itself, which is taken for unit, and which the greater contains three times. On the contrary, the fraction ⅓ expresses the ratio of one magnitude to another greater than itself, which is taken as unit, and which contains the smaller three times.

Having distinguished the numbers or relations of magnitudes, which we have conceived in our minds by particular signs, arithmetic becomes the art of combining these relations with one another; employing for this purpose the signs themselves by which the numbers are distinguished. Hence, the four operations of addition, subtraction, multiplication, and division, include the whole science: for all the different combinations that can be formed of ratios are reduced ultimately to an examination of the excess of some above others, or of the way in which they contain one another. For the purpose, indeed, of facilitating commercial accounts, astronomical calculations, &c., many other very useful rules have been invented, such as the rules of proportion, interest, discount, alligation, position, extraction of roots, progression, &c.; but, on attending to the operations prescribed by these rules, it is easy to see that they are only different applications of the four principal rules.

The particular operations of arithmetic depend in their details on the system of characters by which numbers are represented. Our arithmetic, which is constructed on the denary system of notation, would be entirely changed if more or fewer characters than ten were employed. The Romans used a different notation, and their rules of arithmetic were entirely different from ours. But all arithmetic, in whatever manner numbers may be represented, is ultimately reduced to the four operations or rules already mentioned. Strictly speaking, indeed, the fundamental rules may be reduced to two, addition and subtraction; for multiplication is only an abridged method of repeatedly adding the same number to itself, and division only an abridged method of repeatedly subtracting one number from another.

The numeral system of the Romans was very ill adapted to the purposes of arithmetical calculation; and, hence, in keeping their accounts, and in all their commercial transactions, they made use of the abacus. The astronomers of Greece contrived an ingenious system, by means of which they were able to perform the most complex arithmetical operations. (*See* NOTATION.) The Indian numerals, on which the modern system of practical arithmetic is founded, were received from the Saracens of Spain, and appear to have been partially introduced into the other countries of Europe in the fourteenth century; but there is no evidence of their having come into general use before the invention of printing. The facility afforded by the Indian numerals in the performance of all numerical calculations has been one of the main causes of the great and rapid advancement of modern mathematical science.

The first complete treatise on practical arithmetic, in which the numerals now in universal use were employed, was written by Tartalea, and published in the year 1556. It consists of two books, the first containing the application of arithmetic to the purposes of civil life; and the second the foundations of the principles of algebra. A less perfect treatise had been published by Tunstall in 1526, and another by Stifel or Stifelius, 1544: since that time works on the science have been almost infinite.

Arithmetic acquires several distinctive appellations, from the particular manner in which it is used, or the purpose to which it is applied: thus,

Binary Arithmetic. The art of expressing and combining numbers by pairs, and by means of two cha-

racters only. A system of arithmetic of this sort was invented by Leibnitz, and also by De Lagni, and traces of it have been found in the early monuments of China. Suppose the two characters to be 1 and 0; the zero multiplying any number after which it is placed by 2, as in the denary scale, it multiplies the preceding number by 10, the first ten numbers on the binary scale would be represented thus: 1=one, 10=two, 11=three, 100=four, 101=five, 110=six, 111=seven, 1000=eight, 1001=nine, 1010=ten.

Decimal Arithmetic, which requires a series of ten characters, the progression proceeding according to the powers of ten. It is this which is universally employed by modern nations; the term, however, is generally applied to those operations in which fractions occur, the fractions proceeding according to the descending powers of ten; that is, the unit is considered as divided into tenths, the tenths into hundredths, and so on. It is very remarkable that the Hindoos, who have so long been acquainted with the denary notation, are still ignorant of its application to fractions. The Moors, from whom it was transplanted into Europe, were equally unacquainted with this application. The invention of decimal fractions, which has doubled the efficiency of our arithmetical system, is generally ascribed to Regëomontanus.

Duodecimal Arithmetic, in which the multiples and divisors of unity proceed according to the powers of 12. This is adapted to our system of lineal and superficial measures, in which the foot is divided into 12 inches, the inch into 12 lines, &c., and is accordingly generally used by artificers.

Sexagesimal or *Sexagenary Arithmetic*, which descends by the powers of 60. The system of subdivision was introduced into the Alexandrian school by Ptolemy, for the purposes of astronomical calculation. The partition of the circumference of the circle into 360 degrees, was probably founded on the property that the chord of one-sixth of the circumference is equal to the radius. Having divided the radius into 60 equal parts or primes, the angle of the hexagon naturally followed the same division; hence, one part or prime was equivalent to the 360th part of the whole circumference. The degree was by analogy subdivided into 60 minutes, the minute into 60 seconds, and so on. Ptolemy ascribes the reason of adopting this method of division to the facility which it affords in calculation; and his commentator Theon adds that 60 is the most convenient of all numbers, inasmuch as being sufficiently small it has a considerable number of divisors.

Political Arithmetic. The application of arithmetic to researches connected with civil government, such as the number of inhabitants of a country, the quantity of food necessary for their consumption, the labour they can accomplish, the mean duration of life, the produce of the soil, the frequency of fires or shipwrecks, &c. In applying arithmetic to inquiries of this sort, we have three principal objects in view; the first is to procure precise facts; the second to deduce from the observed facts the consequences to which they lead, and the third to determine the probability both of the facts and the consequences. (*See* STATISTICS.)

Universal Arithmetic. The name given by Newton to algebra, or the calculation of magnitudes in general. The operations of ordinary arithmetic are founded on two distinct classes of principles; the first are independent of the particular signs by which numbers are expressed, the second depend on those signs. The general properties of numbers, which are independent of any particular system of notation, form the subject of universal arithmetic.

ARITHME'TICAL COMPLEMENT — of a number is what it wants of the next higher decimal denomination. Thus 4 is the arithmetical complement of 6, because it is what 6 wants of 10. In like manner 43 is the arithmetical complement of 57, and 432 of 568: the number and its complement, when added together, always producing a sum which is expressed by 1, followed by as many ciphers as there are digits in the number. It is used in logarithmic calculation to avoid the trouble of subtraction: for example, if two logarithms are given, and a third is to be subtracted from their sum, the whole operation may be performed at once, by writing the reciprocal of the logarithm to be subtracted, and adding the three together.

Arithmetical Mean between two numbers is a number such that its excess above the first is equal to its defect from the second, or it is a number equal to half their sum: thus 10 is an arithmetical mean between 7 and 13. An arithmetical mean among any number of quantities is found by adding all the quantities together, and dividing by the number. Thus, let there be six numbers, 1, 3, 4, 6, 7, 9; a mean among them is 5, for their sum is equal to 30, and 30 divided by 6 gives 5.

Arithmetical Progression. A series of three or more numbers, such that each differs from that which precedes or follows it by the same number: thus, 3, 5, 7, 9, 11, form an arithmetical progression, in which the common difference of the terms is 2. The general expression of this progression is a, $a+d$, $a+2d$, $a+3d$, &c.

Arithmetical Proportion. Four numbers are said to be in arithmetical proportion, when the difference between the first and second is the same as the difference between the third and fourth: for example, 2, 5, 6, 9.

Arithmetical Ratio. The difference between any two terms of an arithmetical progression.

ARMA'DA. (Spanish military or naval force.) This name is peculiarly applied in English history to the fleet assembled by Philip II. in 1588, for the conquest of England. The Spaniards, with their usual inflation of language, termed it "Invincible." It consisted of 150 ships, carrying 2650 guns, and having on board 20,000 soldiers, besides volunteers, and 3000 seamen. The account of its misadventures and dispersion is well known. The reader who is curious to consult a new and careful relation of this celebrated passage in history, will find it in Southey's *Naval History of Great Britain*, forming a part of the *Cabinet Cyclopædia*. The best Spanish account of the transaction will be found in Herrera.

ARMADI'LLO. A Spanish epithet, applied to a genus of small South American macronykous or edentate quadrupeds, characterised by a defensive armour of small polygonal bony plates, which covers the head, trunk, and sometimes the tail. Linnæus applied to this genus the term Dasypus, by which the Greeks, with more propriety, designated the hare and rabbit.

AR'MAMENT. (Lat. *Armamentum*.) A force equipped for war, naval or military. In Roman antiquities, armamenta comprehended the rigging and tackling of a ship, its sails, sailyards, oars, ropes, &c. Hence "Arma" denotes the sails (Virg. Æn. v. l. 55.) and the rudder (ib. vi. l. 353.) of a vessel.

ARMI'LLA. (Lat. armilla, *a bracelet*.) In Ornithology, the coloured circle of the distal naked end of the tibia, above the tarsal joint.

ARMI'LLARY SPHERE. (Lat. armilla, *a bracelet*.) An ancient astronomical machine, composed of an assemblage of hoops or circles, representing the different circles of the system of the world, as the equator, the ecliptic, the colures, &c. put together in their natural order, and occupying their proper relative positions.

ARMI'NIAN CHURCH. The Arminians are Christians of the Eutychian or Monophysite doctrine, which recognises only one nature in the Saviour, viz. the Divine; and the procession of the Holy Ghost from the Father only. They hold the seven sacraments of the Romish Church, and the doctrine of transubstantiation: their clergy is also divided into secular and regular. From the wide dispersion of the Arminians over the commercial regions of the east, their form of Christianity is also considerably diffused, although it appears to be strictly a national church of which none but Arminians are members. Since the last war between Russia and Turkey (1829), the place where the principal of their four patriarchs resides (Etchmiadzine), has been transferred from the latter to the former government. There is also at Constantinople, and in other parts of the Levant, an Arminian Roman Catholic Church, owning the supremacy of the Pope. There is a well known congregation of Arminian monks on the island of San Lazaro, near Venice, who have published a variety of useful works in the language of their country.

ARMI'NIANS. Those who hold the tenets of Arminius, a Protestant divine, born in Holland in the year 1560. They are thus summed up: —

1st. God from all eternity determined to save all who he foresaw would persevere in the faith, and to condemn all who should continue in unbelief.

2d. Christ atoned for the sins of all mankind, but those only who believe partake of the benefit of that atonement.

3d. Man is of himself incapable of true faith; therefore regeneration by the Holy Spirit, given of God through Christ, is necessary.

4th. All good works are to be attributed to the grace of the Holy Spirit, which, however, does not force a man against his own inclination.

5th. God gives to the truly faithful the means of continuing such. With respect to the possibility of a defection from this state of grace, Arminius and his immediate followers expressed themselves undecidedly; but it came afterwards to be considered a part of the character of Arminianism to affirm the possibility.

The assertors of these opinions in Holland were vehemently attacked by the Calvinistic party, which was prevalent at the time; and in 1610 the Arminians addressed a petition to the States of Holland for protection, from which they derived the name of Remonstrants. In the year 1618, nine years after the death of Arminius, the synod of Dort was convened by the States General, and a hearing given to both parties. The Arminian opinions were defended by Episcopius, divinity professor at Leyden; but his side complained that they were unfairly treated, and the conditions of the discussion violated to their prejudice. They were condemned by the Synod,

and treated in consequence with great severity, being forbidden to exercise the ministry in public: many of them fled to Antwerp, France, and other quarters.

From this period their opinions underwent a considerable change; and the articles above stated, which seem little different from the tenets of the Lutherans, began to be so explained as almost to do away entirely with the idea of the necessity of succour from the Holy Spirit. From hence they proceeded to reject many matters of faith, and to simplify materially the articles requisite for salvation. They proposed to draw up such a comprehensive and liberal scheme as should embrace all Christians, with the exclusion of the Romanists. They considered it sufficient that a man should receive the Holy Scriptures as the rule of faith, and allowed each individual to interpret them for himself, only adding thereunto the necessity of moral duties and good works. The Papists were excluded on the score of morality, as admitting the lawfulness of persecution.

There is no longer any particular sect to which the name Arminian is exclusively applied; but the opinions above stated are adopted in England by one branch of the Methodists, who follow therein the views of their founder Wesley, and by many individuals of the church of England, and other denominations. The articles of the English church have been represented by different parties as inclining both to Arminianism and Calvinism; and Whitby, and Taylor, bishop of Norwich, are among the most famous of her friends who have maintained the Arminian tenets.

A'RMISTICE. (Lat. armistitium.) In National Law, a truce or suspension of hostilities.

A'RMOUR. (Lat. armatura.) A term applied to those artificial means by which man is wont either to protect himself or to annoy his enemy, hence called defensive and offensive. *Defensive* armour includes those arms specially used for the defence or protection of the body, as cuirasses, helmets, &c. The materials used in their construction are exceedingly multifarious, varying in many instances according to the products of the country in which they are fabricated, but depending in general on the judgment and experience of the inhabitants. *Offensive* arms, or those used in attack, are of different kinds; 1. For cutting, such as the sabre; 2. For thrusting, such as the straight sword, the bayonet, pike, lance, &c.; 3. For throwing, such as the mortar, rocket, howitzer, &c.; and lastly, for shooting, such as guns, pistols, carabines, rifles, and cannons. Lucretius traces the progress of offensive arms very minutely: —

> "Arma antiqua manus, ungues dentesque fuere,
> Et lapides et item sylvarum fragmina, rami
> Et flammæ, atque ignes postquam sunt cognita primum;
> Posterius ferri vis est, ærisque reperta;
> Et prior æris erat quam ferri cognitus usus."

The history of armour is identified with that of every nation; and an elaborate discussion of this subject would throw great light upon questions of mythology, poetry, jurisprudence and civil polity, and strikingly display the progress of civilisation. Into such details, however, our limits necessarily preclude us from entering, and we can only refer the reader to Meyrick's work upon this subject (3 vols. 4to. London, 1824), which the student of the politics, arts, manners, and wars of antiquity and the middle ages, may consult with great benefit.

ARMS, or ARMORIAL BEARINGS. In Heraldry, the name given to the devices borne on shields or coat armour. Family coats of arms are divided by heralds into perfect and imperfect. Perfect are, 1. Abstract, or warranted by regular descent. 2. Terminal, belonging to the brethren of the right line. 3. Collateral, borne by brethren of the heir male. 4. Fixal, in third degree by right line of male heirs. Imperfect are, 1. Granted by the king, with a lordship. 2. The gift of a king, derived by a herald. 3. The ensign of a Saracen won in the field. 4. Heir female of close branch. 5. Arms of bastardy.

A'RMY. (Fr.) Lit. men in arms. A body of men organised and disciplined for military service, commanded by a chief or leader, with subordinate officers in regular gradation, and supported both in time of peace and war for the preservation of internal quiet and defence against foreign aggression. An army is generally divided into a certain number of corps, each consisting of brigades, regiments, battalions, and squadrons. When in the field it is formed into lines: the first is called the vanguard, the second, the main body; the third, the rear-guard or body of reserve. The middle of each line is occupied by the foot; the cavalry forms the right and left wing of each line, and sometimes squadrons of horse are placed in the intervals between the battalions. In the history of armies we may distinguish those of three different periods: 1. The ancient armies, which, from the time of Sesostris downwards, underwent a series of progressive improvements under the Persians, Greeks, and Carthaginians, till they finally reached a high degree of perfection under the Romans. 2. Those of the middle ages, the offspring of the feudal system, which, however well calculated to keep alive a spirit of ferocity, opposed a fomidable barrier to the revival of the military art, from their contempt of discipline and utter lawlessness. 3. Those that have existed since the invention of gunpowder and the establishment of standing armies. Since the use of gunpowder there have been seven principal periods in the history of the military art. The first extends from the early part of the fourteenth to the end of the fifteenth century. The second begins with the campaign of Charles VIII. in Italy, and extends to the commencement of the wars in the Netherlands, comprising the wars of the French, Germans, and Spaniards in Italy. The third period comprehends the great war of independence, waged by the Netherlands, in order to shake off the yoke of Spain, and extends from 1568 to the general suspension of hostilities in 1609. The fourth period comprises the celebrated Thirty Years' War, and extends from 1618 to 1648. The fifth period comprehends the wars of the French in Italy, Germany, and the Netherlands, as well as the Northern and Turkish wars, and embraces the space of 90 years, viz. from 1648 to 1738. The sixth period includes the three Silesian wars, viz. from the beginning of the first Silesian war in 1740, to the breaking out of the French Revolution in 1792. During these several periods many improvements took place in the composition and discipline of armies; but these were destined to be far surpassed in the seventh and last period, which embraces the military systems and establishments of our own times. In the organisation of the Continental armies great uniformity prevails; but as these are inseparably connected with the political condition of the people, a consideration of their character belongs to the history of these various nations, to which we must refer the reader. The British army, like those of the Continent, is divided into cavalry, infantry, and artillery, and these again into regiments and battalions; but in its composition and organisation an entirely different principle is adopted. While the Continental armies are recruited by conscription, and every officer must have served as a private or a cadet, or have acquired some knowledge of the military art in a preparatory establishment, the ranks of the British army are supplied by voluntary enlistment, and commissions are, with rare exceptions, only attainable, with or without purchase, as a favour from the commander-in-chief. In addition to the officers attached to each separate regiment, the superintendence of the whole army in its various departments and ramifications is entrusted to a commander-in-chief, a secretary at war, a master-general of the ordnance, a paymaster-general of the forces, an adjutant-general, and a quartermaster-general. There are, besides, a board of general officers for the clothing of the army, an inspector of army colours, commissioners of the military college, and commissioners of the military asylum. (For an account of armies in general, vide *Encyc. Brit.* art. *Army*; of the British army, *M'Culloch's British Statistics*; of the Russian, Italian, and French armies, Tanski, Oudinot, and Daniel.)

A'RNOLDISTS. The followers, or rather partisans, of Arnold of Bresica, who in the twelfth century was the first to raise his voice against the abuses and vices of the papacy. He acquired for a time considerable influence among the lower orders, and the tumults which were raised by his supporters caused great uneasiness in Rome, which was the chief scene of his proceedings. He was finally put down by an armed force, made prisoner, and burnt by Pope Adrian IV. Certain heretical notions on the nature of the Eucharist were charged against him; but the insurrection which arose under his auspices was clearly a political disturbance, and his harangues seem to have been directed rather against the morals than the tenets of the church which he attempted to overturn.

ARNO'TTO. *See* ANNOTTA.

ARO'MA. The characteristic odour of substances, especially the strong and peculiar odours of certain plants, whence the term *aromatic*.

ARPE'GGIO and ARPEGGIA'TO. (It. arpeggiare, *to play on the harp.*) In Music, the striking or bowing, if on an instrument of the violin species, the notes of a chord in quick and repeated succession, so as to imitate the harp.

ARQUEBUSA'DE. (From arquebus, *a hand gun.*) An aromatic spirituous lotion, applied to strains and bruises, but originally invented as an application to wounds inflicted by an arquebus.

A'RQUEBUSE, or HARQUEBUSE. A sort of hand gun, used by infantry before the invention of the musquet. The word is of uncertain derivation: the Italian archibuso is said to come from arco, *a bow*, and busio, or bugio, but the meaning of this last seems unsettled. The word is used very loosely in old writers for every sort of fire-arms used by infantry. Gunsmiths are still called arquebusiers in France. In the German, Spanish, and Gascon infantry of the earlier part of

the sixteenth century, the pike and arquebuse-men were intermixed in the same ranks. The barbarous English words hackbut, hackbutteer, which we find in military language in the reign of Elizabeth, are derived from arquebuse, arquebusier. The arquebuse is said to occur first in the descriptions of the battle of Morat in 1476. Arquebusiers on horseback are mentioned in that of the battle of Fornosa, 1494.

ARRACA'CHA. The South American name for an umbelliferous plant, the arracacia esculenta of botanists; whose fleshy sweet roots are cultivated in Columbia and Jamaica, in the mountainous parts of those countries, in the same way as parsnips and carrots in Europe. The roots are of large size, and in quality are when cooked between a sweet chestnut and a parsnip. Attempts to introduce it into common European cultivation have uniformly failed.

ARRA'CK. A spirituous liquor, obtained by distilling the fermented produce of rice; but other spirituous liquors are called by the same name. Arrack has a very strong and somewhat nauseous flavour and odour, derived from a peculiar volatile oil which it contains, and which corresponds with that which gives a sickly and disagreeable taste to our corn spirit.

ARRAI'GNMENT. In Law, the arraignment of a prisoner on a criminal charge consists in calling him to the bar, and (in treason and felony) making him hold up his hand, or otherwise own himself to be the party charged, reading the indictment to him in English, and demanding of him his plea (guilty or not guilty), and entering it accordingly.

ARRE'ST. In Law, in execution of the command of some court of record or officer of justice, may take place either in criminal or civil cases. 1. For treason, felony, or breach of the peace, any person may arrest without warrant or precept. Arrests by public officers may be made either with or without process. Any constable, or even private person, who has a warrant directed to him from a justice of the peace to that effect, may arrest for felony or misdemeanor; and, if the warrant was given without sufficient ground, the justice is responsible. Every warrant should be under the hand and seal of a justice of peace, and specify the day on which it was made out: it seems to be rather discretionary than necessary, although it is usual to specify the cause of arrest in the warrant. 2. Arrest in a civil cause is by process, in execution of the command of some court or officer of justice. On affidavit of a cause of action to the amount of 20*l.* (such cause of action importing a contract or liability, express or implied, and a breach of such contract, and a present debt overdue, unless in some rare cases, in which special orders to hold to bail are given for the causes of action), the plaintiff obtains a writ of capias, which is the proper process for the arrest of one or more defendants who are at large. When a defendant is already in custody in one of the prisons of the superior courts, a writ of detainer to continue such imprisonment at the suit of the new plaintiff is the proper proceeding. The form and effect of the writ of capias (*see* Capias), on which arrest on mesne process takes place, are now regulated by the Uniformity of Process Act, 2 W. 4. c. 39. The sum specified in the affidavit, the sum bonâ fide claimed for debt and costs, and various other particularities, must be indorsed on the capias. A writ of capias may, like a writ of summons, be merely served on the defendant; but when it is intended to arrest, a sheriff's warrant is obtained, on which the defendant is arrested, and a copy of the writ then delivered to him. Arrest must be made within the county, and at any time within four months after the date of the capias, except Sundays, Christmas-day, and Good Friday. If the writ or warrant is so defective as to be absolutely void, the party arrested might legally resist; but if the process were only irregular, such resistance would be an indictable offence. On arrest, the defendant and two sureties usually execute what is termed a bail-bond, conditioned for causing special bail to be put in. (*See* Bail.) But instead of giving bail, he may put into court the sum indorsed on the writ, together with a further sum for costs.

Arrest on a writ of execution (*see* Capias ad Satisfaciendum) is an absolute and perfect execution of the highest nature against the defendant, under which the debtor is imprisoned until satisfaction is made, unless discharged under the Insolvent Act.

A'RRIS. (Probably abbreviated or corrupted from a risega, Ital. *at the projection*, or from the Saxon ariſan, *to arise.*) In architecture, the edge of two surfaces meeting each other, or line of concourse of two planes.

A'RROW ROOT. The commercial name of the starch obtained by washing the grated root of the masanta arundinacea, which it yields to the amount of twenty-five to thirty per cent. It is sometimes adulterated with potato starch, and the fraud is not easily detected; it, however, gives a disagreeable flavour and smell, like that of the raw potato, and forms a less firm jelly with hot water than when the arrow root is genuine.

A'RSENAL. (It. arsenale, from arx, *a citadel.*) A magazine of military stores, or public establishment where naval and military engines are manufactured or stored.

A'RSENIC. (Gr. *ἀρσενικός, strong.*) A very soft, brittle, and eminently poisonous metal, of a steel grey colour: its sp. gr. 5·7. It volatilizes, exhaling a strong odour of garlic, before it fuses, at a temperature of 365° F., and is easily inflammable. It combines with oxygen in two proportions; and as both compounds are sour, and form salts with bases, they have been termed arsenious and arsenic acids: the former is composed of 38 arsenic and 12 oxygen, and the latter of 38 arsenic and 20 oxygen. Arsenious acid is more commonly known under the name of *white arsenic*, and is the usual state in which this poison occurs in commerce; it is obtained during the extraction of several of the metals from their ores, and is a white brittle semitransparent substance, having little taste, but is virulently poisonous. Its sp. gr. is 3·7. It forms a dull white powder, and it is in this form that it is usually sold. When heated in the flame of a candle, it rises in the form of a white poisonous vapour, and exhales, in consequence of its partial reduction, a strong garlicky smell: 1000 parts of cold water dissolve about $2\frac{1}{2}$ of white arsenic; but when the water is boiled with the arsenic, 1000 parts take up between 77 and 78; and this solution, after standing a few days, deposits rather more than half of the white arsenic, in the form of small crystals, retaining about 30 grains in permanent solution. White arsenic dissolves in the alkalies, and combines with the metallic oxides, forming a class of salts called *arsenites:* they are all poisonous. Of these the arsenite of potash is used in medicine, under the name of Fowler's mineral solution: it is employed in very small doses in the cure of agues, and is an effective remedy, but requires much care in its administration.

When white arsenic is taken as a poison, that is, in large doses, it produces violent spasmodic pains of the stomach and bowels, attended by a sense of heat, and constriction in the mouth and throat, an increased flow of saliva, tightness about the head, itching of the face and neck, and nausea. These symptoms are succeeded by vomiting and purging and excruciating pains; the pulse, at first full, hard, and frequent, sinks and becomes irregularly feeble, and clamminess of the skin, cold sweats, purple spots, and convulsions precede death; or if the patient escape this catastrophe, it often happens that hectic fever, paralysis, and mental and bodily debility attend him for the remainder of his days. It is often said that the bodies of persons poisoned by arsenic are very prone to putrefaction; but this does not appear to be always the case. After death the stomach and bowels are usually found inflamed, but often only slightly so; and it appears from Sir B. Brodie's observations, that this poison kills by some peculiar action upon the heart and nervous system. The treatment of persons thus poisoned consists in promoting the vomiting by an emetic, composed of a solution of 20 grains of sulphate of zinc in two ounces of water, aided by copious draughts of warm barley-water or gruel; but the most effective means of getting rid of the arsenic, is by the use of the stomach-pump, which, when immediately resorted to, has often saved the patient. The after treatment requires much circumspection.

The only ready means of ascertaining the presence of white arsenic is by heating the suspected substance upon a red-hot coal, or in the flame of a condle or spirit lamp, when it will exhale the peculiar arsenical odour resembling that of garlic; but the treatment of persons poisoned by arsenic, and its detection in doubtful cases, must be left to the medical man and the chemist. It is impossible too strongly to represent the evil which results from the unfettered sale of arsenic, and from the unwarrantable use of it as a poison for rats, and as a veterinary remedy, for it is thus that it finds its way into culinary vessels, gets accidentally mixed with articles of food, and that bottles which have contained it are used for beer, wine, vinegar, or medicine: its sale should be rigidly prohibited.

Arsenic acid is more soluble and sour, but equally poisonous with the arsenious acid. Its salts are called *arseniates*, and the arseniate of potash obtained by deflagrating a mixture of white arsenic and nitrate of potash is occasionally used in medicine: it is the active ingredient in the tasteless ague drop.

A'RSIS and THESIS. (Gr. *ἄρσις, lifting up, θέσις, laying down.*) In Music, terms used in composition, as when a point is inverted or turned, it is said to move *per arsin et thesin*, that is, when it rises in one point and falls in another; properly speaking, it is the rise and fall of the hand in beating time.

A'RSON. (Lat. ardeo, *I burn.*) At Common Law, signifies the maliciously and voluntarily burning the house of another. This offence is now defined and regulated in its various degrees by the stat. 7 & 8 G. 4. c. 30. The subjects of arson are defined in two sections of this statute: the first, relating to buildings of every descrip-

tion, the latter to stacks of vegetable productions, (both these classes of offences being capitally punishable), and to crops of corn, &c. standing or cut down, plantations, heath, &c., the firing of which is punishable with transportation for seven years.

ART. (Lat. ars.) The application of knowledge or power to effect a desired purpose. The ancients divided the arts into "artes ingenuæ, bonæ" or "liberales," and "artes serviles." Under the latter were comprehended the mechanical arts, because these were practised only by slaves. The former were summed up in the Latin verse,

"Lingua, Tropus, Ratio, Numerus, Tonus, Angulus, Astra;"

and the latter in the pentameter,

"Rus, Nemus, Arma, Faber, Vulnera, Lana, Rates."

In modern times arts are divided into fine and useful, comprising under the former those which have not utility for their direct or immediate object; such as music, poetry, sculpture, &c. (For the history and description of the fine and useful arts, see the respective articles.)

ARTEMI'SIA. (Artemis, *one of the names of the goddess Diana.*) A composite genus consisting of bitter or stimulating plants, of which wormwood, southernwood, and tarragon form a part.

ARTERIO'TOMY. (Gr. ἀρτηρία, *an artery*, and τέμνω, *I cut.*) The opening of an artery: this operation is occasionally performed upon the temporal artery, with a view of relieving inflammatory symptoms about the head.

A'RTERY. (*See* AORTA.) These vessels are usually found empty in the dead body, and were supposed by the old anatomists to be air tubes; they are ramifications of the aorta, and convey the florid blood with a pulsating motion to the different organs and parts of the body.

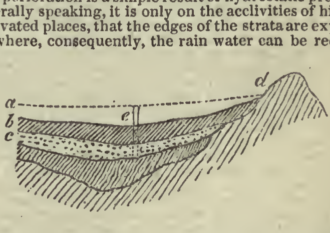
ARTE'SIAN FOUNTAINS, or ARTESIAN WELLS. (Fr. Puits Artésiens.) Vertical perforations of the exterior crust of the earth, of small diameter, and frequently of great depth, through which subterraneous water arises to the surface, often forming abundant and elevated jets. The name Artesian is derived from Artois, a province of France, where especial attention has been given to this means of obtaining water; but it appears, from sufficient historical evidence, that wells of this kind were perfectly well known to the ancients. Niebuhr cites a passage from Olympiadorus, who flourished at Alexandria about the middle of the sixth century, in which it is stated that when wells are dug in the Oasis to the depth of two hundred, three hundred, or sometimes five hundred yards, rivers of water gush out from their orifices of which the agriculturists take advantage to irrigate their fields. The oldest Artesian well known to exist in France is in the ancient convent of the Chartreux, at Lillers in Artois. It is said to have been made in 1126. Others exist at Stuttgard, of great antiquity, though their dates cannot be fixed with precision. The inhabitants of the great desert of Sahara appear also to have been long acquainted with this mode of obtaining water, and the Chinese are said (but the truth of the statement is questionable) to have practised it for thousands of years.

Various conjectures have been made as to the source of the water which comes from the Artesian wells. It was long believed that the water of the sea must necessarily penetrate by way of infiltration into the interior of the continents, and at length form large bodies of subterraneous waters, which, excepting for capillary influences, would not rise above the general level of the ocean. Another opinion, maintained by Aristotle, Seneca, Cardan, and even Descartes, was, that the subterraneous water, from which the sources of rivers and springs are supplied, is the product of the condensation of aqueous vapours ascending from the interior parts of the earth in consequence of the central heat. But these hypotheses are founded on mere conjecture, unsupported by the slightest evidence, and consequently merit no attention. The simplest and most natural explanation is, that the water of ordinary wells, of Artesian fountains and rivers, is supplied by the rain which falls on the surface at a higher elevation, and which penetrates through the pores and fissures of the ground till it meets with some impermeable stratum, or is collected in subterranean reservoirs. It has been objected that springs are sometimes situated on or near the summits of mountains, which could not be supplied in this way; but on an attentive examination of all the circumstances, that is to say, on measuring accurately the extent of surface at a greater elevation than the spring, and comparing it with the quantity of rain that falls annually in the same climate, it has been found, in every instance, that the aqueous deposition from the atmosphere greatly exceeds the supply from the spring. It is computed that not more than a third part of the rain which falls in the valley of the Seine is conveyed to the sea by the river; the remaining two-thirds support vegetation, supply fountains and springs, or are returned to the atmosphere by evaporation. The immense bodies of water which some continental rivers roll towards the ocean are but a small part of the rain which falls in the surrounding countries.

Assuming, then, that the subterraneous water is supplied from atmospherical deposition, it remains to be explained how it arrives at the situation it occupies in the interior of the earth, and by what forces it is raised from great depths to the surface.

All persons who have paid the slightest attention to geology are aware that in stratified countries (and it is in such only that Artesian wells exist) different beds of rocks are superposed on one another, and ranged in a certain constant order. The strata sometimes follow a horizontal direction for a considerable extent of country; at other places they are inclined, and even placed perpendicularly to the horizon, having the appearance of having been bent and burst through by the action of a powerful force from beneath. In those cases the edges of the strata are often exposed, especially on the summits and flanks of hills, to the action of the atmosphere. Between the strata are frequently found beds of permeable sand, through which water, coming in contact with them, must necessarily pass, first, through the inclined part by virtue of its specific gravity, and then in the horizontal branches, by virtue of the pressure of the water remaining in the elevated portions of the strata. In this manner the water insinuates itself between the different strata; and hence we may expect that in localities where the tertiary stratification prevails, as many distinct sources of subterraneous water will be met with in penetrating perpendicularly through the surface, as there are distinct layers of a sandy or gravelly nature reposing on impermeable strata. This consequence of the theory is perfectly confirmed by experience. M. Arago mentions, that in digging for coal near St. Nicholas d'Aliermont, a short distance from Dieppe, seven distinct and copious sources of water were found, the respective depths of which were: 1st, between 80 and 100 feet; 2d, 328 feet; 3d, from 570 to 590 feet; 4th, from 690 to 710 feet; 5th, 820 feet; 6th, 940 feet; 7th, 1090 feet; and the occasional force of each source was very great. Similar occurrences are frequent in the neighbourhood of London, and are familiar to all miners. But it is not enough that the structure of the country is such that water can percolate between the different strata; the phenomena of Artesian fountains could not be explained without supposing it to be collected in large quantities, and forming subterraneous reservoirs of immense extent. That such reservoirs exist, no doubt can be entertained. The celebrated fountain of Vaucluse sends forth at all times a stream of water sufficient to form a considerable river. Even in the driest seasons, when the water is least plentiful, it produces 4780 cubic feet per minute. After great rains, its product is thrice as great. The mean quantity emitted is 9360 cubic feet per minute, or about 5030 millions of cubic feet in a year. Many other examples of the same kind might be cited; showing that water must not only be collected in subterraneous cavities in immense quantities, but that it also passes freely from one place to another. In fact the disposition of the rocks in strata permits the water to be collected under the surface, and to be conveyed without waste, as if in close pipes.

According to the view which has now been taken of the manner in which subterraneous water is collected, its elevation to the surface through a natural fissure or artificial perforation is a simple result of hydrostatic pressure. Generally speaking, it is only on the acclivities of hills, or in elevated places, that the edges of the strata are exposed, and where, consequently, the rain water can be received



under beds of impermeable materials. Conceive two strata of clay or rocks as *a* and *b*, having a bed of sand or other matter permeable to water interposed, and suppose that *d* is the place where the edges of the strata crop out, or where a fissure allows a free entrance of the water to the permeable stratum. The water at first descends through the effect of gravity; it then passes along towards *b* in consequence of the pressure exercised by the superior part of the column near *d*. Now suppose a perforation to be made at *e*, and continued till it reaches through the stratum *a*, the water will naturally continue to rise till it gains the same altitude as *d*, or at least till it reaches the surface if below that altitude. The water in fact between the two impermeable strata is in the same circumstances as in an artificial pipe; and if the surface

of the ground at *e* is considerably lower than *d*, the ascensional force may be sufficient to cause a considerable jet.

Some Artesian fountains, for example that at Lillers in Artois, are situated in the middle of immense plains, where not the most insignificant hill is to be seen on any side. In such cases it may be inquired where we are to look for those hydrostatic columns whose pressure causes the rise of the subterraneous water to the level of the lowest points? The answer is obvious: we must suppose them placed beyond the limits of view; at the distance of 50, 100, or 200 miles, or even at a greater distance. The necessity of supposing the existence of a subterraneous liquid column of two or three hundred miles of extent cannot appear a serious objection, when it is considered that the same geological structure has been found to prevail sometimes over even a much greater extent of country. An interesting paper on this subject is given by Arago, in the "Annuaire du Bureau des Longitudes," for 1835.

ARTHRI'TIC. (Gr. ἀρθρῖτις, *the gout*, or from ἄρθρον, *a joint.*) Gouty pains, chiefly affecting the joints.

ARTHRO'DIC. (Gr. ἀρθρώσις, *articulation.*) A connection of bones in which the head of one is received into a very superficial cavity in another, so as to admit of motion in almost all directions; as in the joint between the *lumeras* and *scapula.*

ARTHRO'DIEÆ. (Gr. ἄρθρον, *a joint.*) A name given to those algæ which, like conferva and oscillatorias, have an articulated structure.

ARTHRODY'NIC. (Gr. ἄρθρον, *a joint*, and ὀδύνη, *pain.*) Rheumatic and other painful affections of the joints.

A'RTICHOKE. (Kharciof, *the Arabic name of the plant.*) A thistle-like plant, called by botanists cynara scolymus, a native of the south of Europe, and now cultivated for its "bottom," that is, for the sake of the fleshy sweet receptacle of its flowers; the harsh hairy substance that is pulled away consists both of the hairy paleæ of the receptacle, and of the feathery pappus of the ovaries. The dried artichokes, called by the French "culs d'artichaut," are the receptacles deprived of the choke and the spiny hard hairs of the involucre, blanched by immersion in boiling water and dried in the sun. Jerusalem artichokes are quite different; they are the tubers of helianthus tuberosus, and derive their name, not from the Holy City, but from a corruption of the Italian *girasole*, a sunflower.

A'RTICLE. A part of speech prefixed to substantives in order to render their signification more or less definite. (*See* GRAMMAR.)

A'RTICLES OF FAITH are the particular points of doctrine which together make up the sum of the Christian belief. The various churches of Christendom, not being agreed upon all these points, have for the most part set forth their own expositions of the whole; and it is to these creeds, symbols, or confessions, that the term articles is most commonly applied. The articles of the English church are 39 in number; the substance of which was first promulgated in 42 articles by Edward VI., in 1553. Under Henry VIII. a committee had been appointed for the formation of ecclesiastical laws, which was renewed under his successor; and in 1551, according to Style, "the archbishop (Cranmer) was directed to draw up a book of articles for preserving and maintaining peace and unity of doctrine in the church, that, being finished, they might be set forth by public authority." From this and the details that follow, it seems that Cranmer composed the articles in their original form, with the assistance of Ridley and others. A great similarity in thought and expression may be traced between many of the articles and the language of the Augsburg Confession: the XIth Article (on justification) corresponds with what Cranmer had previously written on the subject in private memoranda. There has been considerable question raised as to the authorities from which the XVIIth Article (on predestination) is derived; for while some persons have interpreted expressions in it according to the Calvinistic system, others have denied the justice of such interpretation, and have undertaken to show that Cranmer must have referred in the composition of the article to the writings and sentiments of Luther and Melancthon.

On the accession of Elizabeth these articles were remodelled by archbishop Parker, who omitted four of them, introducing four new ones, and altering seventeen. These were again revised by convocation in 1563, some alterations made, and the number reduced to thirty-eight.

The XXXIXth was restored in a final review by Parker in 1571, and then imposed on the clergy for subscription. It is remarkable that in the manuscripts and earliest editions there is one important variation in the admission or rejection of the first clause of the XXth Article, the authority of which may be considered as virtually recognising and establishing it.

ARTICLES OF WAR, the code of military law embodied in the Mutiny Act, which is passed each year.

ARTI'CULATED. (Lat. articulus, *a joint.*) Literally connected by an articulation or moveable joint; but in plants applied to cases where parts are so slightly connected that they finally fall asunder. Thus a leaf is said to be articulated with its stalk when the two finally fall asunder. A flowerstalk is articulated in the middle when it is contracted, and finally separates there into two parts. This separation is called disarticulating. It is a curious fact that the articulation of plants uniformly takes effect across the longitudinal or woody tissue, and never parallel with it; as in the petiole, in a stem at its nodes, in the middle of legumes and other kinds of seed vessels.

ARTI'CULATES, ARTICULA'TA. A term applied by Cuvier to a primary division of the animal kingdom, characterised by an external skeleton in the form of a series of rings articulated together and surrounding the body; by an internal gangliated nervous system; the ganglinus being arranged symmetrically along the middle line of the body (*see* HOMOGANGLIATA), and by having distinct respiratory organs.

ARTICULA'TION. The connection of the bones of the skeleton by joints.

ARTICULA'TION. In Painting and Sculpture, the moveable connection of the bones, in the representation of which by the artist the greatest skill and knowledge of anatomy is required.

ARTI'CULATE or HOMOGA'NGLIATE. Division of the animal kingdom. See those words.

ARTI'FICER. (Lat. ars, *art*, and facio, *I make.*) Lit. one who makes according to art. Among the Romans, artificers had peculiar privileges. They possessed their own temples, and enjoyed an exemption from personal service. An artificer is one who requires intellectual refinement in the exercise of his profession, in contradistinction to artisan, who may practise either the fine or useful arts, but whose knowledge is limited to the general rules of his trade.

ARTI'LLERY. (Fr. artiller, *to fortify.*) In a general sense, denotes all kinds of missiles used in warfare, with the machines by which they are propelled. Since the invention of gunpowder, however, the term has been chiefly confined to large ordnance, namely, cannon, howitzers, mortars, rockets, &c., with their carriages, ammunition, and apparatus of all kinds, including also the troops especially appointed for their management.

The principal military engines of the Romans, which can be properly classed under the term artillery, were the balista and catapulta; the former for throwing stones, the latter for propelling darts and arrows. The invention of the balista is ascribed by Pliny to the Phœnicians; but other authors, among whom are Diodorus and Plutarch, say that both instruments were invented in Sicily. Ælian ascribes them to Dionysius the elder. They were very extensively employed in the later periods of the republic, and under the empire. In the middle ages, engines for assaulting and defending fortified towns or castles were greatly multiplied. Among these inventions are enumerated the espringal, trebuchet, mangona, mangonel, bricolla, petrary, metafunda, berfrey, war-wolf, &c. It is stated in the chronicle of Peter Langtoft, that Richard I. in his wars against the Saracens, had mills in his barges and galleys which were turned by the wind, and threw fire and stones upon the enemy. If the accounts given of the effects of some of these machines may be credited, they must have been of great power, and well adapted to the purpose of battering down walls and fortifications. It is related by Hemingford, that the engines used by Edward I. at the siege of the castle of Stirling, threw stones of 300 pounds weight.

Though the explosive force of gunpowder was known to Roger Bacon in the twelfth century, it was at a considerably later period that fire-arms began to supersede the ancient artillery. Barbour, in his "Metrical Life of Robert Bruce," says that cannon were used by Edward III. in his first campaign against the Scots, A. D. 1327. Du Cange says they were employed by the French at the siege of Puy Guillaume in 1338; but they must have been at that time very uncommon, for Rapin relates that the four cannon employed by Edward III. at the battle of Cressy, in 1346, contributed as much by the surprise they occasioned to the French troops as by their execution to the success of the day. A few years later they seem to have been no longer rare. The most ancient cannon were formed of bars or pieces of iron, soldered to each other lengthwise, and bound together by iron hoops; occasionally lead, or even leather, protected in the same manner, appears to have been employed; and the cannon balls were made of stone. About the middle of the fifteenth century, cannon began to be cast; and it was about the end of the same century that font metal, or bronze, was first used for this purpose. In 1477, when Louis XI. was about to attack the cities of Flanders and Picardy, he ordered bombards or cannon of prodigious length and weight to be cast at Paris, Tours, Orleans, and Amiens. He also ordered iron bullets to be cast at the foundries of Creil, though stone bullets were still in use. Brass cannon appear to have been first cast in England by John Owen, in 1535. A foundery was also established about the same time in Edinburgh, by Robert Borthwick, an artist in the service of James IV. of Scotland. Mortars were

made in England under the reign of Henry VIII. and cast-iron cannon under that of Edward VI. About the beginning of the 15th century, the custom of applying to cannon the names of birds or beasts, from some fanciful analogies respecting their cruelty or swiftness, began to prevail; thence the names falconet, falcon, sacker, culverin, basilisk, dragon, syren, &c. At present cannon take their names simply from the weight of the ball they carry. Thus a piece which discharges a cast-iron ball of 24 pounds, is called a 24-pounder; one that carries a ball of 12 pounds, is called a 12-pounder; and so on. The size of the gun is determined by the service to which it is appropriated; and frequently by the means of transport, or facility of manœuvring. Ship guns and garrison guns, not requiring to be moved from place to place, admit of large sizes, and are frequently made to carry balls of 32, 36, or even 42 pounds. The largest cannon known to exist is a brass one at Beejapoor, which was cast in commemoration of the capture of that place, by Alum Geer in 1685. Its extreme length is 14 feet 1 inch, the diameter of its bore 2 feet 4 inches. An iron shot of the proper size to fill this bore would weigh 1600 pounds.

Mortars are probably as ancient as cannon, and were employed to throw red-hot iron and stones long before the invention of shells. The first account of shells used for military purposes is in 1435, when Naples was besieged by Charles VIII. The howitzer is a species of ordnance of a medium length between the cannon and the mortar, and is used for discharging either shells or large balls at point-blanc, or at a small elevation. It is said to have been invented by Belidor, and was used at the siege of Ath in 1697. It is chiefly made of brass. The carronade, a very short howitzer, was first cast at the Carron Iron Works; from which it takes its name. It began to be employed about the year 1779. Iron-rockets, the invention of Sir William Congreve, were first used at the bombardment of Copenhagen.

ARTILLERY PARK. The place in a camp, or the rear of an army, where the artillery is placed. The artillery is drawn up in lines, one of which is formed by the guns, the others by the ammunition waggons, pontoons, &c.; and the whole is surrounded by a rope, which forms the park.

ARTILLERY TRAIN. A number of pieces of ordnance mounted on carriages, and ready for service.

ARTISAN. *See* ARTIFICER.

ARTOCA'RPEÆ. (Gr. ἄρτος *bread*, καρπὸς, *fruit; bread-fruit tree.*) A considerable division among urticaceous plants, having the fruit composed of flowers combined in fleshy heads, and the stem flowing with an acrid milk. The bread-fruit tree of the South Seas, and the jackfruit, are among the most conspicuous species. With them are associated the upas tree, and the fig, in different genera. The bread-fruit tree itself (artocarpus incisa) is a small tree with broad lobed leaves and large globular heads of fruit; the jack (artocarpus integrifolia) has oblong undivided leaves, and a larger, coarser, and oblong fruit. In all the species of artocarpeæ the flowers are unisexual.

ARTS, FINE. (Lat. artes.) Works imagined and executed by the mind and ingenuity of man. They include painting, architecture, sculpture, poetry, music, rhetoric, and, according to some, dancing. Their history, as respects the three first, will be found under several heads in this work, and a concise account of the philosophy of them under the article *Æsthetics*. They are distinct from the arts simply so called, commonly called the useful arts from their general utility to mankind, because their end is pleasure. The fine arts are the offspring of genius, their model nature, and their master taste. Characterised by simplicity, they should never wander into luxury nor degenerate into extravagance.

ARUNDINA'CEOUS. (Lat. arundo, *a reed.*) Any thing having the general appearance of a reed. The term is confined to glumaceous plants.

ARU'SPICES. Roman soothsayers, who foretold future events from the inspection of the entrails of the victims offered at the altars of the gods.

Their college was not held in the same respect as that of the augurs, and did not consist, like the latter, of men of high distinction; so much so, that Cicero mentions the admission of one of their order to the senate, as an indignity to that body. Like that of the augurs, their art was brought from Etruria.

ARVI'COLA. (Lat. arvum, *a field;* colere, *to inhabit.*) A genus of rodent, or gnawing mammals, of the numerous family of the rat and mouse (*Muridæ*), distinguished by the prismatic form and fangless structure of the molar teeth, and of which the field campagnol (*Arvicola agrestis*) and the bank campagnol (*Arvicola riparia*) are indigenous species; these are commonly confounded with other *muridæ*, under the name of field mice.

AS. A Roman weight nearly answering to one pound, being accurately equal to 10 oz. 18 dwt. $13\frac{5}{7}$ grs. troy weight. It was divided into 12 ounces (unciæ).

It was also the name of a brass coin, which originally weighed one pound; but was subsequently reduced by various degrees at different periods to half an ounce, in consequence of the gradual increase of the value of meta as compared with that of provisions and other necessaries, as civilisation advanced. Its value was a little more than three farthings of English money.

A'SAPHUS. (Gr. ἀσαφὴς, *obscure.*) A name devised to express the obscure nature of the genus of trilobites, fossil crustaceans, to which it is attached; and which is characterised by a tail-like appendage terminating the posterior extremity of the body, sometimes of a semicircular form, sometimes in the shape of a short triangle, and by tuberculate eyes, which have a granular surface arising from the number of compartments (at least 400) on the surface of the cornea, containing each a separate spherical lens.

ASARABA'CCA. (Asarum, *a kind of plant*, and bacca, *berry.*) A small, round, hard, stemless, hardy European herbaceous plant, with chocolate-coloured three-lobed flowers, belonging to the natural order Aristolochiaceæ. It is reputed to be a sternutatory. The French call it cabaret, the public-house plant, as it is said, because it was formerly used as an emetic to relieve the stomachs of people who had been drinking too hard.

A'SARIN. A crystallisable substance, somewhat resembling camphor, extracted from the roots of the Asarum Europæum.

ASBE'STUS. (Gr. ἄσβεστος, *unconsumable.*) A fibrous soft mineral, composed of easily separable filaments of a silky lustre. It consists essentially of silica, magnesia, and lime. It is sometimes woven into cloth, which is incombustible, and may therefore be purified by fire: hence the term *amianthus*, from ἀμίαντος, *undefiled.* This cloth was used in antiquity to wrap the bodies of the dead when about to be burned, to prevent their ashes being mixed with those of the funeral pile.

ASCA'LAPHUS. A Fabrician genus of insects separated from the ant-lions (*myrmeleon*) of Linnæus, and characterised by having nearly equal palpi; maxilla ciliate; labium horny, rounded, and entire.

ASCA'RIDES. (Gr. ἀσκαρὶς, a term applied by Hippocrates to certain intestinal worms.) In modern Zoology restricted to a genus of round worms, or cælelminthans, with a trilobate or trivalvular head, and a double spiculum for the intromittent organ. Two species of this genus infest the human body; one large, found in the small intestines, called Ascaris lumbricoides; the other of very small size, found in the rectum called Ascaris vermicularis.

ASCE'NDING. (Lat. ascendo, *I climb up.*) Is said of any part which, being horizontal at its base, gradually curves upwards, as is the case in many stems. If applied to ovules, it means that they are attached to the placenta by a point intermediate between the lower end and the middle.

ASCENDING NODE. In Astronomy, is that point of a planet's orbit in which it crosses the ecliptic, proceeding northward. (*See* NODE.)

ASCENDING SIGNS. The signs are said to be ascending when they are eastward from the meridian, and consequently approaching the meridian through the effect of the diurnal rotation.

ASCE'NSION. In Astronomy, is either right or oblique: the RIGHT ASCENSION of a star denotes the arc of the equator intercepted between the first point of Aries and that point of the equator which comes to the meridian at the same instant with the star. The most convenient way of defining the place of a star is to refer it to the equator, and to a certain fixed point in the equator from which the degrees are begun to be reckoned. For this purpose astronomers choose the point of the equator at which the sun's path crosses it when he ascends into the northern hemisphere, which is the first point of Aries, or the vernal equinox, and reckon the degrees along the equator eastward, all round the circle. Now, to determine the plane of any star, a great circle is conceived to pass through it, intersecting the equator at right angles. The distance of the star from the equator, measured on this circle, is called its declination; and the distance of the point of intersection of the equator and the circle from the vernal equinox is called the right ascension of the star. The right ascension and declination are thus the two co-ordinates by means of which the plane of any star is determined. The right ascension is reckoned in time, because it is found by observing the time on the sidereal clock which elapses between the passage of the first point of Aries and that of the star over the meridian. When the first point of Aries passes the meridian the astronomical day begins; astronomers then reckon 0 hours 0 min. 0 sec. Suppose a star to come on the meridian 5 hours 35 min. 26 sec. after this; then 5 hours 35 min. 26 sec. is the star's right ascension in time, and is equivalent to an arc of the equator of 83° 51′ 30″, because an hour in time corresponds to 15° in space, and a minute or second in time to 15 minutes or seconds in space. If the clock, therefore, is regulated to keep time with the

heavens, the time indicated by the clock at which any star passes the meridian is the right ascension of the star in time.

The Oblique Ascension of a star is the arc of the equator intercepted between the vernal equinox and that point of the equator which comes to the horizon at the same time with the star. This varies with the latitude of the place of observation. At the equator it coincides with the right ascension. This term is now seldom used in astronomy.

Ascensional Difference is the difference between the oblique and the right ascension. This term is chiefly used in respect of the sun, because when the arc which it denotes is turned into time it shows the time before or after six o'clock of sunrise. The sine of the ascensional difference is equal to the tangent of the latitude multiplied into the tangent of the star's declination; hence, when the declination of a star is north, its oblique ascension is found by subtracting the ascensional difference from the right ascension, and when the declination is south, by adding the ascensional difference to the right ascension.

On account of the greater precision with which observations are made with fixed meridional instruments, all astronomical elements are now computed from observations of right ascension and declination; but in ancient times the positions of the celestial bodies were chiefly referred to the horizon, and hence the *oblique ascensions* and *ascensional differences* entered constantly into the solutions of astronomical problems.

Asce'nsion. The reception of our Saviour into glory, after his last appearance on earth: celebrated in the Christian church, from time immemorial, on the last Thursday but one before Whit-Sunday. Rogation week, that in which the ascension is celebrated, is so termed from the rogations (petitions or litanies) which were used in the perambulation of the bounds of the parish, which, according to ancient usage, took place in this week.

ASCE'TICS. (Gr. ἀσκεω, *I exercise.*) Persons who, in the early ages of Christianity, devoted themselves to a solitary and contemplative life, following the system of the Essenes and Therepeutæ among the Jews, and practising great austerities, with a view to mortify the flesh and abstract the mind from worldly objects. They had their origin in Egypt and Syria, and appear to have suggested the first idea of monachism.

A'SCI. (Gr. ἀσκὸς, *a bottle.*) Little membranous bags or bladders, in which the seed-like reproductive particles or spores of lichens, fungi, &c. are enclosed.

A'SCIANS, or ASCII. (Gr. α, *without*, and σκιὰ, *shadow.*) A term found in the older works on geography, and used to denote those inhabitants of the globe who at certain times of the year have no shadow. This can only happen with respect to the inhabitants of the torrid zone, who, twice a year, have the sun in the zenith.

ASCI'DIAN, ASCIDIA. (Gr. ἀσκὸς, *a bottle* or *pouch.*) A genus of heterobranchiate acephalous molluscs, or tunicaries, characterised by a body having the form and commonly the consistence of a tough leather pouch, attached to some foreign substance, and with two openings, one branchial, and the other anal, from which streams of water are forcibly ejected when the animal is touched or irritated.

AS'CIDIUM. (Gr. ἀσκὸς, *a bottle.*) A hollow pitcher-shaped body found upon the stems of certain plants, as nepenthes, sarracennia, &c. It usually contains water, and is sometimes clothed with reflexed hairs, which prevent the escape of insects which fall into it; its use is unknown. In nepenthes, sarracennia, cephalotus, and dischidia, it is in reality a leaf rolled up till its edges touch, when they grow together; in marcgraavia, it is a bract in the same state.

ASCI'TES. (Gr. ἀσκὸς.) Dropsy of the belly.

ASCLEPIADA'CEÆ. (Asclepias, *one of the genera.*) Monopetalous exogenous plants, with bifollicular fruit, the stamens adhering to the stigma, which is large and pentagonal, and an acrid milk in their stems. They are exceedingly different in appearance, some being trees with showy flowers, others obscure twiners with very inconspicuous herbaceous corollas, others herbaceous plants with clusters of gaily coloured flowers, and others leafless decumbent shrubs with angular stems and brown putrescent flowers. The latter are stapelias. Hoya, with its delicate waxen flowers running with honey, is a genus of the order; and another is the curious climbing water carrier called dischidia, which mounts to the tops of lofty trees with its fleshy bags filled with a constant supply of water. Some of the species are valuable for the toughness of the fibre extracted from their stems. The milky secretion of these plants contains caoutchouc, or Indian rubber; it is of an emetic nature, and in some cases it is dangerous. Asclepias tuberosa, the butterfly weed of North America, is the handsomest of the hardy species. This order only exists in temperate climates, and is most copious in the tropics.

ASH. (Celt. ac, *a point;* its wood being used for pikes.) The fraxinus of botanists, consists of several species of hardy trees, usually valuable for their timber. The tough ash wood of carpenters is yielded by Fraxinus excelsior, and the sweet substance called manna by Raxinus ornus. They mostly bear flowers without petals; but the latter species having those organs is called, in distinction, the flowering ash.

A'SHLAR. (Ital. asciare, *to chip.*) In Architecture, common freestones, as they are brought rough and chipped or detached from the quarry, of different lengths and thicknesses. Their usual thickness is nine inches.

ASHLERING. (From same as last.) In Architecture, the upright timber or quarters towards the rooms or inwards in garrets by which the slope of the roof is concealed — sometimes it is only two or three feet high, and sometimes the whole height of the room.

ASH-WEDNESDAY. The first day in Lent, called in the Latin church dies cinerum, *the day of ashes;* it being customary on that day for penitents to appear in church clothed in sackloth, upon which occasion ashes were sprinkled upon them.

ASI'LUS. A Linnæan genus of dipterous insects, in which the mouth is furnished with a horny, projecting, straight, two-valved sucker, and gibbous at the base: antennæ filiform, approximate, of two articulations; body, oblong and conical in shape. The insects of this genus prey on other insects, especially those of the dipterous and lepidopterous orders.

ASP. (Gr. ἀσπὶς, *an asp.*) A species of poisonous serpent frequently mentioned by ancient authors, some of whom describe its bite as being inevitably mortal, and say that the bitten die within three hours, and without pain, being thrown into a deep sleep; whence it was selected by Cleopatra as the instrument with which at once to terminate her existence, and bereave her conqueror of the chief feature of his triumph. There is always much difficulty in identifying the precise species mentioned in the classical writings of antiquity, from the vague manner in which they are there alluded to. Some naturalists are of opinion that the species of hooded viper, called by the modern Arabs 'El Haje' [Vipera (Naja) Haje, Cuvier] is the 'Aspis' of the ancients; and as it possesses the power of distending the skin of the neck, like the Indian Cobra di Capello, it agrees with one of the characters assigned by Pliny to the Aspis — "Colla aspidum intumescere," lib. viii. The size, however, of the Haje, which varies from three to five feet, is greater than that which is usually attributed to Cleopatra's asp.

ASPA'RAGIN. A white crystallisable substance obtained from the expressed juice of asparagus. It has been proposed as a diuretic in medicine.

ASPA'RAGUS. (Gr. σπαράσσω, *I tear.*) A genus of spiny plants, many of which are shrubs, and climb upon other plants. They all have minute scale-like leaves, small white or greenish flowers, and berried fruit; very often they produce short leafless branches, in room of leaves. Asparagus officinalis, one of the few species which neither climb nor bear spines, is found wild occasionally on the seashore near Weymouth. The succulent shoots which it throws up from its underground eyes are the asparagus of the market gardeners. It is not a little singular, that although this plant has been an object of careful cultivation for so many years, it should never yet have produced a well-marked permanent variety; the sorts, as they are called in the shops, are produced by casual differences of soil or cultivation, and are not distinct varieties.

ASPARA'GINOUS PLANTS. In Hort. In a strict sense, this term ought to be applied only to such plants as belong to asparagineæ; but in horticulture it is used to signify all those culinary vegetables the points of the tender shoots of which in spring, when they nearly emerge from the soil, are eaten, in the same manner as those of asparagus: such, for example, as the points of the common hop, of the sea-kale, &c.

ASPA'RTIC ACID. When asparagin is boiled with magnesia it is resolved into ammonia and a peculiar acid called as above.

A'SPECT. In Architecture, the direction towards the point of the compass in which a building is placed. The aspectus is also used by Vitruvius to denote the external distribution of a temple. Thus he describes seven sorts of aspects of temples: that in Antis, the Prostyle, Amphiprostyle, Peripteral, Dipteral, Pseudodipteral, and Hypæthral; under which words they are severally described.

Aspect. In Astrology, the angle formed by the rays of light proceeding from two planets, and meeting at the earth, and which are supposed to possess some natural influence. (*See* Astrology.)

Aspect. In Hort. In speaking of the inclination of the surface of the ground, the word aspect is used with reference to the sun, as the word exposure is with reference to the wind. Hence, a garden, the surface of which slopes to the east, has an eastern aspect, and also an eastern exposure; but a garden on a flat surface, sheltered by plantations on the east, west, and north, cannot be said to have any aspect, while it has a southern

exposure, being open to the winds of the south, though sheltered from those blowing from the other cardinal points of the compass.

ASPERGI'LLIFORM. (Lat. aspergillus, *the brush with which holy water is scattered about in Roman Catholic places of worship.*) Any thing shaped like that instrument; it is chiefly used in speaking of the stigmas of grasses.

ASPERGI'LLUM. A genus of tubicolar Bivalves, characterised by the soldering of both valves to the inner surface of the calcareous sheath; which is dilated or club-shaped at the lower end, and perforated there by many small holes, whence it has obtained the trivial name of the "Watering-pot Shell." In the system of Cuvier, this rare and remarkable genus ranks among the Family *Clausa*, of the Class *Acephala testacea*.

ASPERIFO'LIÆ. (Lat. asper, *rough*, folium, *a leaf.*) The name given by Linnæus to the plants now called Boraginaceous.

ASPE'RMOUS. (Gr. ἀ, *without*, σπέρμα, *seed.*) Destitute of seed.

ASPHA'LTUM. (Gr. ἀ, priv. and σφαλλω, *I slip*, from its use as a cement in ancient building.) A black brittle bitumen, very fusible and inflammable; it is soluble in naphtha, and forms a good varnish. It is found upon the surface and banks of the Dead Sea (hence called Asphaltic Lake), and in large quantity in Trinidad and Barbadoes; the ancients employed it in some of their cements, and it was used also in the art of embalming.

ASPHODE'LEÆ. (Asphodelus, *the principal genus.*) Subdivision of the natural order Liliaceæ, comprehending the onion, the squill, the ornithogalum, anthericum, asparagus, and similar genera. They differ from true liliaceæ in little beyond their flowers being usually smaller. (*See* Liliaceæ.)

ASPHY'XIA. (Gr. ἀ, *without*, and σφύξις, *pulsation.*) A fainting fit: a state of body in which the pulse cannot be felt, and in which the powers of mind and body are suspended.

ASPIDORTRY'NCHUS. (Gr. ἀσπὶς, *a shield*, ῥύγχος, *a beak.*) The name of a fossil extinct genus of sauroid fishes characterised by the length and bony covering of the upper jaw.

ASSAFŒ'TIDA. A fetid gum resin obtained from the root of the *ferula assafœtida*, whence it exudes by incision in the form of a milky juice, which, when dried by exposure to the sun, acquires a mottled appearance and pink colour. It is a native of the south of Persia, and is used in medicine as a stimulant and antispasmodic in hysteric and nervous disorders, and in spasmodic cough, asthma, and flatulent colic.

ASSA'I. (Ital. *enough.*) In Music, an adverb of quantity prefixed to such words as allegro, adagio, &c., signifying that the motion of the bars or measures should be kept at a mean rate of quickness or slowness, quick or slow enough, but not too much so in one or the other case.

ASSA'SSINS. Those who attack and kill by treachery and violence persons unprepared for defence. The word is derived from a military and religious order, formed in Persia by Hassan Ben Sabah, about the middle of the eleventh century, and called Assassins from their immoderate use of Haschischah (henbane), which produced an excitement amounting to fury. Hammer, in his History of the Assassins, has opened some new and striking views of the origin, proceedings, and doctrines of this sect. Their principal seat was in the mountains; and they were subject to the control of a prince, or, according to Hammer, a grand master, who possessed such an ascendency over his fanatical subjects that they paid the most implicit deference to his commands, esteemed assassination meritorious when sanctified by his mandate, and courted danger, and even certain death, in the execution of his orders. Nor did they stoop to humble prey; for the more lofty the object of their hatred, the more sure and deadly was their aim. In the time of the crusades, they mustered to the number of 50,000, and presented a formidable obstacle to the arms of the Christians. Among the victims of their swords, at this period, may be mentioned Conrad, Marquis of Montferrat, who was murdered in the market-place of Tyre, in the year 1192. Several historians have charged upon Richard I. the instigation to this crime; but it is a point which none have succeeded in elucidating. Long after this period the Assassins continued to levy contributions in return for the safety which they afforded to distinguised individuals; but they were at length, after an obstinate resistance, effectually crushed by the sultan Bibars. Scattered abroad, however, hated and despised, the order of the Assassins, like that of the Jesuits, endured long after its nominal suppression, and the mountainous regions of Kuhistan offered for a time a secure asylum to those who still lingered in their faith. Remnants of the Assassins still exist both in Persia and Syria, but merely as one of the many sects and heresies of Ismalism, and utter strangers to the murderous tactics of their predecessors.

The numerous battles and enterprises of the Assassins, their valorous defence against the armies of the crusaders and the great sultan Bibars, and the adventurous character of their whole history, opened a fertile source to the Syrian romance writers, of which, according to Hammer, they have freely and skilfully availed themselves.

ASSAU'LT. (Lat. assilio, *I leap upon.*) In Law, generally speaking, a violent kind of injury offered to a man's person. The nature of an assault has never been precisely defined; some lawyers being of opinion that a blow or an attempt to strike alone constitutes the offence, others including under this category irritating or abusive language.

Assault. In War, an effort made to carry a fortified post, camp, or fortress, wherein the assailants do not screen themselves by any works. During an assault, to avoid endangering their own party, the batteries of the assailants cease to play.

Assault. In Fencing, a mock engagement with foils, in imitation of a real single combat.

ASSA'Y. (Fr. essayer, *to try.*) This term is sometimes employed as synonymous with analysis, but more generally restricted to the determination of the composition and consequent value of alloys of gold and silver. From the quantity of coin, plate, and trinkets constantly fabricated, the art of assaying is of much importance, and requires considerable practical skill in its performance. At the mint there are two assay masters, the master's assayer and the king's assayer: the business of the former is to receive the gold and silver ingots brought for coinage, to cut one or more pieces from each ingot, and to make written reports of each assay. The king's assayer examines the melted bars previous to their passing into the moneyers' hands for coinage, and is responsible for their standard purity: and when the money is coined it is not allowed to go out of the mint until pixed; that is, until it has been ascertained, by the assay of one piece taken out of each journeyweight of coin, that it is of standard purity: the king's assayer therefore is a check officer upon the melter and upon the moneyers, and is responsible for the standard purity of all gold and silver coin issued from the mint. About twelve grains of gold, and twenty grains of silver, are usually employed for the assay.

ASSE'MBLY. In French history, the four great legislative bodies which succeeded each other during the period of the Revolution, are usually termed, 1. The *National* or *Constituent Assembly;* commenced 17th of June, 1789, by the resolution of the deputies of the communes in the States-General, constituting themselves a national assembly, to which the deputies of the nobles and clergy afterwards adhered; termed Constituent Assembly, from having framed a constitution: dissolved on the acceptance of the constitution by the King, 30th of September, 1791. 2. The *Legislative Assembly:* it commenced its sittings October 1. 1791; suspended the royal authority by its decree of the 10th of August, 1792; and was dissolved September 21. 1792. 3. The *Convention* (*see* Convention): it commenced its sittings September 21. 1792, with a proclamation of the Republic; was dissolved 4 Brumaire, 4th year of the Republic (Oct. 26. 1795). 4. Two-thirds of this assembly were then included in the new body of the "Corps Legislatif," which commenced its sittings Oct. 27. 1795, forming two councils, 1. of 500 (des Cinq-cens); 2. of the Ancients (des Anciens), 250 in number. The latter body named the Directory. This assembly subsisted until the dissolution of the Directory by Bonaparte, 19 Brum. 8th year of the Republic (Nov. 10. 1799). (*See* Directory.)

Assembly, the General, of the Kirk of Scotland, is the highest ecclesiastical court of that establishment. It meets annually in May, and sits for ten successive days, with power to appoint a commission to take cognizance of any cases undecided within that period; the commission being in fact a continuation of the assembly, with one additional minister named by the moderator. The assembly consists of representatives from the presbyteries, royal burghs, and universities of Scotland, and from the churches in the East Indies connected with the Kirk: in all about 380 members. The meeting of the assembly is attended by a nobleman as representative of the king, with the title of Lord High Commissioner; who, however, takes no part in the proceedings. The moderator, or president, is chosen by the assembly yearly. The General Assembly is a court of appeal from the Presbytery and Synod.

ASSE'SSMENT OF DAMAGES. *See* Damages.

ASSE'SSOR. In Law, a person possessed of knowledge of the law, appointed to advise and direct the decision of the judge. In various inferior courts assessors are appointed by statute. Assessors were employed, previously to the Reform Act, to assist the returning officer in deciding on the cases submitted to his cognizance at the period of an election. By the Municipal Corporation Reform Act (5 & 6 W. 4. c. 76. s. 37.) the burgesses of every borough are directed to elect two assessors, for the purpose of assisting the mayor in his duty of revising the burgess lists and presiding at the

elections. And, by sect. 43. the burgesses of each ward are to elect two assessors for the purpose of assisting the alderman at the ward elections.

A'SSETS. In Law, are the fund out of which a deceased person's debts are to be paid. Assets by descent are liable to those debts only which are secured by specialty, as bond or covenant binding the party's heirs; but assets in the hand of executors or administrators are liable to all debts.

ASSIE'NTO TREATIES. In History, the contracts entered into by Spain with several European nations (first Portugal, then France, and after the peace of Utrecht in 1713, England), to supply her South American colonies with negro slaves from Africa, were so termed.

ASSI'GNATS. Paper-money issued by the French government at various periods during the Revolution, based on the security of the unsold lands of the clergy, emigrated nobles, &c., which had become forfeit to the nation.

ASSI'GNMENT. In Law, is the total alienation of a chattel interest: which, by the third section of the Statute of Frauds, must be, if of a term of years in land, by writing and signature. *Assignee* is the party to whom an assignment is made.

ASSIMILA'TION. (Lat. assimilatio.) The act by which organised bodies incorporate foreign molecules and convert them into their own proper substance.

ASSI'ZE. (From the Norman French assise, *session.*) 1. In a sense now obsolete, an ordinance or constitution of the sovereign: thus, the code of feudal law framed for the kingdom of Jerusalem is termed the Assizes de Jerusalem. 2. The ordinances regulating the price of bread and other necessaries, were also called Assizes. 3. The peculiar jury by which a writ of right was tried, was termed the Grand Assize. 4. In the only sense in which the word is now an existing law term, the assize signifies the periodical session held by the judges of the superior courts in the counties of England, for the purpose of trying issues at nisi prius and delivering the gaols. (*See* COURTS, SUPERIOR.)

ASSO'CIA'TION. In Psychology, a name given to that property of our minds, by which any object or state of consciousness (whether image, thought, or emotion) has a tendency to recal other states or objects of consciousness with which it has been previously in some way connected. The conditions under which this tendency exists were first stated by Aristotle, in his "Treatise on Memory and Recollection." According to him they are threefold, consisting of Resemblance, Contrast, and Contiguity. If by the last word we understand connexion in space and time, and that of cause and effect, this division is the same with that given by Hume, and adopted by modern philosophers. The principle of association has been applied by Hartley, Sir J. Mackintosh, and other writers on ethics, to explain the origin of our more complex emotions, and in particular of our moral sentiments.

ASSOCIATION. In Politics, a society formed of a number of individuals acting under common rules and an elective government, for the accomplishment of some definite object. The principle of association is so obvious as to need no comment or explanation. But its practical developement in politics and ethics in modern times, owing in great measure to the facility of communication and diffusion of intelligence, is a feature in society of vast and daily increasing importance. The value of a combination of means and wills is plain and undeniable,—Firstly, in cases where the object pursued is pecuniary advantage. Undertakings which it would be impossible for individuals to embark in, either from the great actual outlay required, or the great amount of pecuniary responsibility imposed (such as the establishment of banks, great public works, distant commercial enterprises, &c.), are every day carried into effect with success and profit by companies. Secondly, in cases where the object is to raise and direct the disposal of a large amount of funds, with a view to the accomplishment of certain ends. Such are associations for purposes of education, for the distribution of Bibles, charitable institutions, &c. &c. And thirdly, we may mention a class of associations, common in all times, but which have far more frequently failed with actual loss than accomplished their object; associations, namely, for the purpose of controlling the rate of profit or of labour. (*See* COMBINATION.) But besides these ordinary instances of association, the present times appear more peculiarly favourable to the formation of societies having in view the accomplishment of political or moral objects, by controlling the action of governments or individuals. These are wholly distinct from those which we have before enumerated. Their purposes do not generally require a large outlay, nor (except in some occasional contingencies) much actual and definite co-operation. Their main object generally is to overrule by a display of associated numbers; occasionally also to bring combined energies to bear upon particular points. They serve to concentrate the action of the wills of many separate individuals, by inducing every man to abandon a portion of his own particular views, and take up instead of them the views of the majority of his co-associates. Of this character were, in France, the clubs which exercised so great a power during the Revolution; and those which, in calm times, are said to have contributed materially towards bringing about the second revolution of 1830: the society "Aide toi et le ciel t'aidera" more especially. In our own country, the history of political unions and associations of late years is abundantly well known. The most powerful that we have hitherto seen was the famous Catholic Association, formed in May, 1823, dissolved in March, 1829, when its great object, the passing of the Catholic Relief Bill, was attained. Of associations having moral instead of political objects, and falling within the category last described, perhaps (if we exclude the Freemasons, from the want of any definite purpose which appears to distinguish them) the Temperance Societies of late years afford the most singular examples; the more remarkable, because their great end is one which (except in a very few instances, such as the exclusion of spirits from ships, &c.) cannot be attained by combined action, unless in so far as it may influence the action and will of individual men.

It is impossible to deny the power of political associations; and it cannot be wondered at that they are regarded favourably by the state in such countries as America, where the principle of democratic associations pervades everything; with distrust by aristocratic governments, in which the power of a ruling class is exposed to danger from their attacks; and altogether suppressed as far as possible under arbitrary governments. Yet it may be questioned whether the tendency of modern opinion is not greatly to overrate that power. It is essentially of a temporary character. At the moment of a doubtful crisis in politics, the expression of the will of an associated multitude will often turn the scale through the mere weight of intimidation. But even with the best organisation, they seem to be radically unfit for the accomplishment of objects requiring untired zeal and perseverance. In the first place, by fettering the individual will of their members, they destroy a great portion of the collective energy in the attempt to concentrate what remains. No mind capable of achieving great objects ever voluntarily works in the trammels of an association. They become therefore, for the most part, passive bodies, guided solely by the will and management of a few individuals among them, who are flattered by the exercise of a power resembling sovereignty, but who are themselves, perhaps, rather fettered than aided in their activity, by the necessity of managing the large masses which they drag along with them. Perhaps no history affords so remarkable an example of the apparent splendour and real weakness of political associations on a large scale, as that of the Jesuits. Their company was formed on an admirable organisation; it had one precise object, the spread of the Roman Catholic faith; one definite principle of union, implicit obedience: the means put within its reach were enormous. It spread and flourished amazingly, exerted the most boundless activity, and excited naturally the most exaggerated fears among its opponents. And yet it would be difficult to say in what it has contributed to the objects it had in view. It has made no conquests over Protestantism; for in Bohemia, France under Louis XIV. &c., where it made the greatest show of effectiveness, its operations merely followed in the train of military oppression or state persecution. It has effected no permanent conversions among the heathen. It has done little or nothing, notwithstanding great show and immense expense, in the way of national education on Roman Catholic principles. Its learned men, with few exceptions, have done still less toward advancing the cause of true knowledge. Nor has a single mind of great originality and power been developed within the boundaries of the institution.

Nor is it possible to speak without great doubt of the moral good produced by the extension of the spirit of association. Some valuable remarks on this subject will be found in an article of Dr. Channing, reprinted from the North American Review, with the title "Remarks on Associations." "One of the most remarkable features of our age," he says, "is the energy with which the principle of combination, or of acting by joint forces in associated numbers, is now manifesting itself. Men have learned what wonders can be accomplished in certain cases by union, and seem to think that union is competent to anything. You can scarcely name an object for which some institution has not been formed. Would men spread one set of opinions and crush another? they make a society. Would they improve the penal code, or relieve poor debtors? they make societies. Would they encourage agriculture, or manufacturers, or science? they make societies. Would one class encourage horse-racing, and another discourage travelling on a Sunday? they make societies. We have immense institutions spreading over the country, combining hosts for parti-

cular objects. We have minute ramifications of those societies, penetrating everywhere, and conveying resources from the domestic, the labourer, and even the child, to the central treasury." — "Associations often injure free action by a very plain and obvious operation. They accumulate power in a few hands, and this takes place just in proportion to the surface over which they spread. In a large institution a few men rule, a few do everything; and, if the institution happens to be directed to objects about which controversy exists, a few are able to excite in the mass strong and bitter passions, and by these to obtain an immense ascendency. Public opinion may be so combined, and inflamed, and brought to bear on odious individuals or opinions, that it will be as perilous to think or speak with manly freedom as if an inquisition were open before us. It is now discovered that the way to rule in this country is by an array of numbers, which no prudent man will like to face. Of consequence, all associations aiming or tending to establish sway by numbers ought to be opposed. They create tyrants as effectually as standing armies. Let them be withstood from the beginning. No matter whether the opinion they intend to put down be true or false, let no opinion be put down by such means: let not error be suppressed by an instrument which will be equally powerful against truth, and which must subvert that freedom of thought on which all truth depends."

A'SSONANCE. In Rhetoric and Poetical Composition, a jingle or imperfect rhyme, formed by separate words, or members of a sentence.

ASSU'MPSIT, or trespass on the case on promises, in law, is an action of an anomalous character, having the form of tort and the substance of contract. It is, properly, a claim of damages sustained through the breach of a simple contract (*i. e.* a promise not under seal), and alleges that the defendant assumpsit promised or undertook to perform the acts specified. It has become the most ordinary remedy, not only where unliquidated damages, but also where debts are sued for; the law implying a promise to pay or do whatever the defendant is legally liable to pay or do.

ASSU'MPTION. A festival of the Romish church, kept on the 15th of August, in celebration of the alleged miraculous ascent of the Virgin into heaven.

ASSU'MPTIVE ARMS. In Heraldry, such as may be assumed with the approbation of the sovereign, or grant from the proper officers of arms: also, in another sense, armorial bearings improperly assumed.

ASSU'RANCE, or INSU'RANCE. A contract for the payment of a certain sum on the occurrence of a certain event. The term assurance is generally confined to those contracts under which a certain sum is to be paid on the death of an individual or individuals now living; while insurance is applied to those which provide for the payment of a sum on the occurrence of events not depending on the duration of human life, and which may never happen, such as the loss of ships at sea, the destruction of houses by fire, &c.

Assurances on Lives, are contracts which stipulate for the payment of a certain sum of money on the death of one or more individuals, in consideration of an immediate payment, or, more frequently, of an annuity or annual contribution, to be continued during the existence of the lives assured. Contracts of this kind are of immense importance to society. Every man whose income depends on his own life or exertions, and on whom others are dependent for support, must be sensible of the advantages of arrangements by means of which, at a small sacrifice of immediate comfort, he is enabled effectually to provide against the casualties of life. They are of a totally different nature from gambling. Though nothing can be more uncertain than the continuance of an individual life, yet nothing is more invariable than the duration of life in the mass; consequently, the exact value of life assurances can be calculated without any uncertainty whatever, and a man, by effecting an assurance, secures to his representatives, against the risk of accident, the advantages they would have from his enjoying his exact proportion of the average duration of life. Such transactions provide against destitution, and tend directly to the accumulation of capital; they will, therefore, be encouraged and protected in all well-governed communities.

Method of computing the Value of Assurances. The value of assurances on lives are computed in nearly the same manner as those of annuities, the principles being the same in both cases. A table of mortality must first be selected, from which we deduce the probabilities of living over the different years of life. Having obtained these, and assumed a rate of interest, we proceed as follows: let the probabilities that an individual of a given age will live over

$$1,\ 2,\ 3,\ 4,\ 5,\ \&c.\ \text{years}$$
$$\text{be } p_1,\ p_2,\ p_3,\ p_4,\ p_5,\ \&c.\ \text{respectively;}$$

also, let r be the rate of interest, and $v = \frac{1}{1+r}$, and suppose that the sum assured is to be paid at the end of the year in which the life fails. Now, the value of 1*l.* to be received at the end of the first year is v, but it will not be received if the life continues to the end of the year; and, as the probability that the individual will live over the year is p_1, the probability that he will not live over it is $1-p_1$, therefore the value of 1*l.* to be received at the end of the year, subject to the contingency of the life failing in the first year, is $(1-p_1,)\ v$. The probability that the life will continue to the end of the second year is p_2, and that it will continue one year only, p_1, therefore $p_1 - p_2$ is the chance it will drop in the second year; and the value of 1*l.* to be received at the end of the second year is v^2, therefore the present value of 1*l.* to be received if the life fails in the second year is $(p_1 - p_2)\ v^2$. In like manner, the probability that the life will fail in the third year is $p_2 - p_3$; and the value of 1*l.* to be received at the end of three years is v^3, therefore the present value of 1*l.* to be received at the end of three years, if the given life fails in the third year, is $(p_2 - p_3)\ v^3$. The same process is continued from year to year, till the probability of living over a year becomes nothing. Now, the whole value of the assurance is manifestly equal to the sum of all its partial values for the different years; therefore, denoting the value by I, we get

$$I = (1-p_1)\ v + (p_1 - p_2)\ v^2 + (p_2 - p_3)\ v^3 + \&c.$$

or, separating this into two series,

$$I = v\ (1 + p_1 v + p^2 v^2 + p_3\ v^3 + \&c.)$$
$$- (p_1 v + p_2 v^2 + p^3 v^3 + \&c.)$$

But it is shown in the article ANNUITY that the series $p_1 v + p_2 v^2 + p_3 v^3 + \&c.$ denotes the value of an annuity of 1*l.* on a life, the probabilities of the continuance of which are represented as above; therefore, calling this annuity A, we have $I = v\ (1 + A) - A$.

Since $v = \frac{1}{1+r}$, this formula becomes by substitution

$$I = \frac{1}{1+r}\ (1 - r\,A).$$

The sum now found is what ought to be paid down, in order to receive 1*l.* on the failure of the given life; but by far the most usual practice is to pay for the assurance by means of an annual premium, the first payment being immediate, and the others at the end of each successive year. Let π be the annual premium; then the value of all the premiums after the first is obviously the same thing as the value of an annuity of the same amount, and is, consequently, equal to πA. Hence, the value of all the premiums is $\pi + \pi A$, or $\pi\ (1 + A)$, which is necessarily equivalent to the assurance. We have therefore the equation $\pi\ (1 + A) = v\ (1 + A) - A$, whence $\pi = v - \frac{A}{1+A}$

This formula is very easily computed when we are in possession of a table of annuities, and it shows at once the annual sum which an individual of any age ought to pay, in order to secure to his representatives 1*l.* (and, consequently, any other sum) at his death.

Temporary Assurances. The values of temporary assurances, or engagements to pay a certain sum in case a given individual dies within a given number of years, are easily found from those on the whole of life. For example, let it be required to find what sum ought to be paid for 1*l.*, to be received if an individual now aged 40 shall die within seven years. Let I be the value of 1*l.* to be paid on the death of a person aged 40, and I_7 the present value of the same sum, to be paid on the death of a person aged 47. Seven years after this the value of an assurance of 1*l.* on the death of the person now aged 40 will be I_7; but the present value of 1*l.*, to be received certainly at the end of seven years is v^7, and the probability that the life will continue seven years is p_7; therefore the present value of I_7, on the contingency that the life will not fail within seven years, is $p_7\ v^7\ I_7$; subtracting this from I, the value of 1*l.* to be received certainly at his death, there remains $I - p_7\ v^7\ I_7$, to denote the value of the temporary assurance. This may be expressed by the following rule. Multiply the assurance on a life seven years older than the given life by the present value of 1*l.*, payable seven years hence, and also by the probability that the given life will survive seven years; subtract the product from the assurance on the given life, and the remainder is the value of a temporary assurance for seven years in a single payment.

In order to find the equivalent annual payment, it must be recollected that the first payment is made immediately, and that seven payments are to be made in all; consequently, all the payments after the first are equal to a temporary annuity of the same amount for six years, or one year less than the given term; consequently, if π represent the annual premium, and A′, a temporary annuity of 1*l.* for one year less than the given term, the value of all the premiums to be received is $\pi + \pi A'$ or $\pi\ (1 + A')$, which by hypothesis is equal to the assurance; consequently, to find the annual premium, we have to divide the value of the temporary assurance in a single payment by $1 + A'$.

In the same manner, the value of an assurance on any number of joint lives is found: it is only necessary to substitute for A in the above formulas, the value of an annuity on the joint lives. Thus, let M be the value of an annuity, to continue while A and B both live, then $v(1 + M) - M$ is the value of an assurance to be paid at the end of the year in which the first of the two lives shall fail, and the equivalent annual payment is $v - \frac{M}{1 + M}$.

A very important class of assurances comprehends those in which the contract is to pay a sum on the death of one party, provided that another party shall be then alive. The computation of the values of such contracts is somewhat more intricate, and cannot be explained without entering into details respecting the manner of combining the probabilities of life, which our limits will not permit.

For assurances on ships and goods, *see* INSURANCE.

ASSU'RGENT. (Lat. assurgere, *to rise up.*) Rising in a curve from a decurved base.

A'STACUS. (Lat. astacus, *a lobster.*) The name of a Fabrician genus of insects, and now the type of a family (*Astacidæ*) of Decapod, Macrourous, or long-tailed Crustaceans; including the lobsters (*Astacus* Leach), the craw-fish (*Potamobius* Leach,) and the cray-fish or spiny lobsters (*Palinurius* Leach). The distinguishing character is derived from the antennæ, the two pairs of which are inserted in the same horizontal line; the mesial ones having moderate or long footstalks, terminated by two filaments; the outer ones naked, or furnished with a scale, which never entirely conceals the base.

A'STERISK. In Diplomatics, a sign in the figure of a star, frequently met with in ancient Latin manuscripts, and seeming to serve various purposes; sometimes to denote an omission, sometimes an addition, sometimes a passage which appeared remarkable on any account to the copyist.

A'STERISM, in Astronomy, denotes a collection of stars. It was formerly used in the same sense as constellation, but is now generally appropriated to any small cluster of stars, whether forming part of a particular constellation, or otherwise.

A'STEROI'DS. A fantastical name by which the four small and recently discovered planets, namely, Juno, Vesta, Ceres, and Pallas, have been sometimes designated.

ASTE'RN. (A, and stern.) A sea term, denoting, in the hinder part of the ship, or behind the ship.

ASTHE'NIC. (Gr. ἀ, *without*, and σθένος, *strength.*) Asthenic diseases are those which are prominently marked by great and direct debility.

A'STHMA. (Gr. ἀσθμαίνω, *I breathe hard.*) A disease, the leading symptoms of which are difficulty of breathing, coming on at intervals, accompanied with cough, and more or less expectoration. The fit most frequently occurs in the night during the first sleep, suddenly awaking the patient, and lasting for three or four hours or more. It is a terrible, but in itself rarely a fatal, disease, though it often lays the foundation of organic mischief. Its proximate cause has not been very clearly ascertained.

A'STOMOUS. (Gr. ἀ, *without*, and στόμα, *a mouth.*) Certain mosses whose theca has no aperture.

A'STRAGAL (Gr. ἀστράγαλος, *a die or huckle bone.*) In architecture, a small moulding whose profile is semicircular. Some have said that the French call it talon, and the Italians tondine; but this is a mistake, and the word is only properly applied to the ring which separates the capital from the column. The astragal is sometimes cut into representations of beads and berries, and a similar sort of moulding is used to separate the faces of the architrave.

ASTRA'GALUS. (Gr. ἀστράγαλος, *a die.*) The ancle bone. The ancients used the corresponding bones of animals as substitutes for dice.

ASTRÆ'A. (Gr. ἄστρον, *a star.*) A genus of lithophytous Polypes; the polypiary or calcareous skeleton of which is characterised by sessile, star-shaped lammellate cells, crowded upon the upper surface. The species are divided into rayed Astreæ (*Ast. radiatæ*), with the stars separated from the base; and toothed Astreæ, (*Astreæ denticulatæ*), with the stars contiguous.

A'STROLABE. (Gr. ἄστρον, *a star*, and λαμβάνω, *I take.*) A circular instrument used for taking or observing the stars. The ancient astrolabe consisted of two or more circles, having a common centre, and so inclined to each other as to enable the astronomer to observe in the planes of different circles of the sphere at the same time. For example, if the circles were at right angles, the instrument would give both longitude and latitude, or the right ascension and declination of star. The equatorial, the altitude and azimuth instrument, and the theodolite, are instruments which answer the same purpose as the ancient astrolabe. Ptolemy changed the form of the ancient instrument, and reduced it to a plane surface, to which he gave the name of planisphere; and, from this circumstance the term astrolabe has been used in modern times to denote a planisphere, or stereographic projection of the sphere on the plane of one of its great circles.

ASTRO'LOGY. (Gr. ἄστρον, *a star*, and λόγος, *discourse.*) According to its derivation, this term should signify the science or knowledge of the stars. Originally, the terms astrology and astronomy were used indifferently in the same sense; but for a long time the former has been employed to denote the vain and superstitious study of predictions and horoscopes; while the latter has been reserved to denote the true science of the celestial motions. According to Lalande, this distinction began to be observed in the time of Clement of Alexandria, that is, in the second century. Astrology is generally coupled with the epithet judicial, from the judgments drawn from it relative to future events.

Judicial astrology is supposed to have had its origin in Chaldea, whence it passed into Egypt, Greece, and Italy. The desire of penetrating into futurity is so congenial to the human mind, that this pretended science has found favour in all ages and countries; and it is a remarkable fact, that astronomy, which demonstrates the frivolity and absurdity of its predictions, was long indebted to it for the principal part of its own progress. Kepler, in the preface to the Rudolphine Tables, observes, that astrology, though a fool, was the daughter of a wise mother, to whose support and life the foolish daughter was indispensable. At the present day it is only among the most ignorant vulgar, or the unenlightened tribes of Asia and Africa, that astrology is held in esteem; but the triumph of sound science and the spirit of philosophy has been slow and difficult. So late as the year 1705 the conductor of "The Connaissance des Tems" thought it necessary to apologise for the absence of all predictions in that astronomical work, by stating, that the Academy had never recognised the solidity of the rules which were given by the ancients for discovering the future by the configurations of the stars; and, what is still more surprising, the first lunar tables calculated according to the Newtonian theory were intended to be subservient to the calculation of nativities.

Astrological predictions are founded on the positions or aspects which the sun, moon, and planets have relatively to each other at the moment of birth, or some other critical period of a person's life, and certain arbitrary influences supposed to belong to each of those bodies. For the purpose of facilitating the determination of the aspects, the whole heaven, visible and invisible, is divided into twelve equal parts by the horizon, the meridian, and four other circles passing through the north and south points of the horizon, and the points of the equator (or rather the prime vertical, or sometimes the ecliptic, for the practice was not uniform), which are at the distance of 30 and 60 degrees from the meridian. These equal spaces are called the twelve houses of the heavens, and the circles by which they are circumscribed are called circles of position. The circles of position are supposed to remain fixed, so that a celestial body is carried through each of the twelve houses in the course of a day by the diurnal rotation. The first house is contained between the eastern horizon and the next circle of position, going to the eastward; consequently the seventh will commence with the western horizon, and the tenth with the meridian or culminating point of the ecliptic. The beginning of the first house, or the point of the ecliptic just rising, is called the horoscope. The first house is the house of life; the second, of riches; the third, of brothers; the fourth, of parents; the fifth, of children; the sixth, of health; the seventh, of marriage; the eighth, of death; the ninth, of religion; the tenth, of dignities; the eleventh, of friends; and the twelfth, of enemies. Each of the houses has one of the heavenly bodies as its peculiar lord. They have also different powers, the strongest of all being the first, and the next in power the tenth; so that if two planets are equally powerful, ceteris paribus, that will prevail which is in the stronger house.

Having made the preliminary arrangement of the heavens, the next object is to consider the aspects or configurations of the influential bodies. Aspect, as defined by Kepler, is the angle formed by the rays proceeding from two planets, and meeting at the earth, and which have the property of producing some natural influence. The ancients reckoned five aspects, namely, the conjunction denoted by the character ☌, the opposition by ☍, the trine by △, the quadrile by □, and the sextile by ⚹. These names and characters, besides several others added in more recent times, are retained in our almanacks to the present day. In the aspect of conjunction the angle made by the two planets is 0; in the opposition it is 180°. The trine is the third part of a circle, or 120°; the quadrile is 90°, and the sextile 60°. With regard to the influences of the aspects, they are benignant, malignant, or indifferent. The quadrile and opposition are considered as malignant or adverse; the trine and the sextile as benignant or propitious; and the conjunction an indifferent aspect.

It now remains only to ascribe certain influences to each of the planets, and to suppose all animals, plants, countries, &c. subject to their control, in order to obtain an idea of the nature of the astrological art. The influences ascribed to the planets were of course as arbitrary as those ascribed to the aspects. Saturn being at the greatest distance from the sun was supposed to be of a cold nature; Jupiter, Venus, and the Moon, temperate and benignant. Saturn and Mars were the most dangerous. The Sun and Mercury participated in the properties of the one and the other, according to circumstances. But these influences were exerted in an infinite number of ways, according to the houses which the planets happened for the time to occupy.

It would be superfluous at the present day to adduce any serious argument against a system of imaginary influences and arbitrary rules, having no other foundation than the ignorance and superstition of mankind, and contradicted by every result of true science, and every dictate of common sense. The celestial bodies pursue their courses in obedience to unalterable laws; and the legitimate business of the philosopher is to discover those laws, to trace out their consequences, and to apply the results of his discoveries to alleviate the wants or multiply the comforts of humanity.

ASTRONOMY. (Gr. ἀστρον, *a star*, and νόμος, *a law.*) The science which treats of the motions, distances, arrangement, and magnitudes of the celestial bodies; of their constitution and physical condition, and, in general, of whatever can be known respecting them.

There is no branch of human knowledge of which the results appear at first sight more at variance with the impressions of our senses. The first aspect of the heavens leads us almost irresistibly to imagine ourselves placed in the centre of a starry sphere; which, in its diurnal revolution, carries along with it all the heavenly bodies. But the changes of relative position which some of the most remarkable among them continually undergo, soon make it evident that they do not all belong to the same sphere. Further observation and reflection lead us to conclude that the apparent daily revolution of the firmament is merely an illusion occasioned by the diurnal rotation of our own earth, which, instead of remaining fixed at the centre, is carried forward about the sun with a velocity of about 19,000,000 of miles in a second of time, or four times that of a cannon-ball when it leaves the mouth of a cannon. The sun, which appears to be of very moderate dimensions, is a body whose volume is 1,384,470 times greater than that of the earth, and placed at a distance of 95,000,000 of miles; and the stars, which even in the best telescopes appear only as luminous points, are bodies of the same nature as the sun; many of them, probably, far surpassing it in magnitude.

Different Classes of Heavenly Bodies. By far the greater part of the celestial bodies appear to be fixed in the firmament, and to preserve invariably the same relative positions. These are the *fixed stars.* A second class comprehends a small number which are continually shifting their positions among the stars, and are perceived to accomplish a complete revolution of the sphere in stated intervals of time. Hence they were called *Planets,* that is, *wandering stars,* from a Greek word signifying to wander. They describe orbits, very nearly circular, about the sun. Some of them are accompanied by smaller bodies revolving round them, as the moon revolves round the earth, and which are called *Satellites,* or attendants. A third class comprehends bodies differing greatly from those now mentioned, and which sometimes exhibit very extraordinary appearances. These are the *Comets.* Like the planets they are obedient to the attractive force of the sun; but the orbits which they describe are exceedingly elongated, and they are only visible when near the sun. Hence they appear at distant or uncertain intervals, and only for a short time; and consequently their physical nature is very imperfectly known. The sun, planets, satellites, and comets form a system of which all the members are connected with and act upon one another in obedience to the law of universal gravitation. (*See* PLANETS, SATELLITES, SUN, and the other terms, in their respective places.)

Uses of Astronomy. Mere curiosity, without reference to practical utility, would prompt mankind to study the movements of the vast machine which rolls over our heads; but the applications of astronomy to the affairs of life are so numerous and important, that an accurate knowledge of its principles is almost indispensable to society. 1st, It is by means of the celestial bodies that we are enabled to determine the relative positions of points on the surface of the earth; to fix geographical latitudes and longitudes, and ascertain the form and dimensions of our planet. 2d, It is to astronomy that we are indebted for all the advantages resulting from navigation. Without an accurate knowledge of the positions and motions of the heavenly bodies, it would be impossible for the mariner to traverse the ocean, or to venture in safety beyond the sight of the shore. With this knowledge he can direct his course with unerring certainty to any given coast; and the ocean, which, without this science, would present an insuperable barrier to the intercourse of distant countries, is rendered "the highway of nations." 3d, Astronomy also presents us with the means of establishing the divisions of time necessary for the regulation of civil affairs, and of fixing chronological epochs. The diurnal revolution of the sphere gives the smaller divisions of time; the revolution of the moon gives the month; that of the sun, the year; and the various configurations of the planets mark out periods of all magnitudes, from a few months or years to millions of ages.

Divisions of Astronomy. The first object of the astronomer is to ascertain, with all possible precision, the apparent places of the stars, or their projections on the sphere, in order to obtain an accurate knowledge of their apparent motions and periods. But it is not enough to have ascertained their positions and motions; the results of observations made at different places and distant times must be compared, in order that we may be enabled to distinguish the movements which are real from those which are only apparent, and depend on our own position with regard to objects observed. And when the real paths described by the different bodies have thus been determined, we are next led to investigate the causes of the phenomena, and the expressions of the mechanical forces necessary to produce them. Hence, the science of astronomy may be divided into *practical, rational,* and *physical:* the first embracing all that is necessary for determining the apparent motions; the second being devoted to the real motions; and the third to the physical causes by which the different motions are regulated and perpetuated.

Practical Astronomy. In order to determine the positions and motions of the celestial bodies, it is necessary to have the means of measuring time and space with the utmost precision. But neither time nor space can be measured without the aid of very refined instruments and contrivances. Hence, the theory of instruments, the method of using them, and the determination of the different corrections that must be applied in order to free the observed positions from the various instrumental and physical errors by which they are affected, belong to this division of the science. A complete knowledge of the sphere and its various circles, as also of the methods of spherical trigonometry, is requisite to the practical astronomer. Observation gives him the place of a star only with reference to his own zenith, or horizon, or to another star whose place is already determined. But their positions must be reduced; that is, referred to invariable planes or circles, in order that the observations made in different places may be capable of comparison with one another. Without such reductions, the observations are of no use.

Rational Astronomy. This division includes the determination of the real orbits, and the laws of motion which the different bodies observe, and the construction of hypotheses by the aid of which we may calculate the positions in advance. In the infancy of astronomy, and before observations became very numerous, or were made with precision, various hypotheses were invented to explain the apparent motions. Thus Ptolemy explained the inequalities of the planetary motions, by supposing each of the planets to describe a circle about a centre moving uniformly round the earth in the circumference of another circle. Tycho Brahe supposed the planets to revolve in circular orbits about the sun; and the sun, accompanied by the planets, to revolve round the earth. Copernicus supposed the earth, as well as all the other planets, to revolve in circular orbits around the sun. All these hypotheses served to explain the phenomena that were known at the time they were respectively invented; and have been successively exploded by more accurate observations, which have proved that the planetary orbits are not circles but ellipses, having the sun in the focus which is common to all of them.

Physical Astronomy. By this term is generally understood the application of mathematical science to the investigation of the laws by which the motions of the celestial bodies are regulated, the nature of the forces by which their motions are maintained, and the effects of their action on one another. By comparing the momentary deflection of the moon's orbit from a straight line with the effects of terrestrial gravity, as manifested in the descent of falling bodies near the surface of the earth, Newton found that both the phenomena were produced by one and the same cause, and that the moon is retained in her orbit by the attraction of the earth. Subsequent investigations, founded on the general laws of the planetary motions, discovered by Kepler, led him to the conclusion, that a force of the same nature extends through the universe; and that all bodies in the heavens and on the earth gravitate towards each other with forces directly as their quantities of matter and inversely as the squares of their distances. By this single principle he explained the elliptic motions of all the planets and satellites; the facts which concern their figures, rotation, and the position of

their axis; and the oscillations of the fluids with which they are surrounded. The quantity of matter in the sun is vastly greater than in the largest of the planets; hence all the planets are principally controlled by the sun, and circulate about him in elliptic orbits, nearly in the same manner as if they were independent of the attractions of one another. Still their mutual influences are sufficiently perceptible; though, from being comparatively small, they are regarded merely as disturbing the sun's action. The calculation of the disturbing forces, or of the effects produced by the mutual attraction of all the bodies in the solar system, forms the most difficult and the most important problem ever submitted to mathematical analysis. Its solution has occupied the most eminent mathematicians of the last and the present century; and the successive advances made towards it by Newton, Clairaut, D'Alembert, Euler, Lagrange, and Laplace, have surrounded their names with a halo of glory.

History of Astronomy. The study of the heavens has occupied the attention of mankind in all ages of the world. At the remotest epochs of historical record, the Chaldean shepherds and the Egyptian priests had found a near approximation to the length of the solar year, and determined, by the comparison of a long series of recorded or traditional observations, periods of time after which the eclipses of the sun and moon return in nearly the same order, and were consequently able to predict these phenomena. The early philosophers of Greece exhausted their imagination in idle speculations about the formation and nature of the universe; but the names of the constellations which they have transmitted to us with their theogonies prove that they had paid considerable attention to the arrangement of the principal stars. Pythagoras appears to have had a distinct notion of the true system of the world; affirming that the earth was not placed in the centre, but revolved about the sun. But the first recorded observations which contributed in any way to the real progress of astronomy were made at Alexandria, under the Ptolemies, about 300 years before our era, by Aristillus and Timocharis, who determined the positions of some of the principal zodiacal stars, and thereby afforded Hipparchus the means of arriving at his important discovery of the precession of the equinoxes.

Hipparchus, the founder of Grecian astronomy, observed at Rhodes about 140 years B. C. This illustrious man appears to have paid little regard to the theoretical speculations of his contemporaries, but adopted the only method by which a correct knowledge of nature can be obtained, namely, assiduous and accurate observation. Among his important discoveries are the precession already mentioned; the length of the solar year; the eccentricity of the sun's orbit; the periodic time of the moon's revolution with respect to the stars, to the sun, to her nodes, and her apogee; the eccentricity and inclination of the lunar orbit. He invented the planisphere, determined the places of 1080 stars, and was the first who introduced into geography the method of fixing the positions of places on the surface of the earth by means of their latitudes and longitudes.

The name of Ptolemy is still more celebrated than that of Hipparchus; though, as an astronomer, he occupies a far inferior rank. His principal astronomical discovery is the inequality of the moon's motion, technically called the evection; but his fame chiefly rests on his great work called Syntax, or Composition; in which he explains the apparent motions of the sun, moon, and planets, according to a hypothesis invented by Apollonius of Perga, some centuries before, and which consists in supposing each of these bodies to be carried by a uniform motion round the circumference of a circle called the epicycle, the centre of which is carried uniformly forward in the circumference of another circle called the deferent. This second circle may be the epicycle of a third, and so on as long as inequalities remain to be explained; the earth occupying a position near, but not at, the centre of the last circle. This hypothesis is utterly demolished by a few accurate observations of the present day; but in the time of Ptolemy it served to explain all the deviations from circular motion then known, particularly the phenomena of the stations and retrogradations of the planets; and it was even of service to astronomy, by offering a means of reducing the apparent irregularities of the planetary motions to arithmetical calculation. Ptolemy's share of the merit belonging to the invention of this ingenious hypothesis consists in the determination of the proportion between the radius of the epicycle and that of its deferent circle, and between the velocity of the planet and the velocity of the centre of its epicycle. The Ptolemaic system continued in vogue till the revival of astronomy and the other sciences in the fifteenth century, when it gave place to theories founded on more enlarged views and more accurate observations.

Fourteen centuries elapsed between Ptolemy and Copernicus; and during this long interval, astronomy continued nearly in the same state. The elements of the solar and lunar tables had indeed received many corrections; and various improvements in the methods of observing and calculating had been introduced, principally by the Arabs; but in respect of theory, no change had taken place. But an epoch had now arrived when men's minds could no longer be held in thraldom by reverence for ancient authority; and a spirit of investigation and inquiry had arisen, which produced the happiest results in all the departments of natural science. Copernicus, guided perhaps in some measure by the opinions of Pythagoras, but more by his own meditations on the planetary phenomena, and the comparison of the numerous observations accumulated by Purbach, Regiomontanus, and Walther, in the latter half of the fifteenth century, had the glory of establishing the system of the world on its true basis. In his great work, "De Revolutionibus Orbium Cœlestium," published in 1543, he showed that all the apparent motions are easily explained by simply attributing a double motion to the earth; a diurnal rotation about its axis, and an annual motion about the sun. The doctrine of the earth's motion was opposed to the religious dogmas of the age, and accordingly the theory of Copernicus met with great resistance; but as observations now began to be greatly multiplied, and to be performed with greater accuracy, the evidences in favour of it daily acquired strength, and in a short time commanded universal assent among astronomers. Tycho Brahe, indeed, an excellent observer, and one to whom astronomy is under the greatest obligations, made an attempt to save the ancient prejudices; while he explained the phenomena by supposing the sun, accompanied by the planets, to perform a diurnal revolution about the earth. This system, however, on account of its physical improbability, never obtained many followers.

The next important step in astronomy was made by Kepler. By means of a laborious comparison and calculation of observations, Kepler discovered that the orbits of the planets are not circles but ellipses, having the sun in one of the foci. He also found that the motion of any planet in its elliptic orbit is so regulated, that the spaces passed over by a straight line drawn from the planet to the sun are equal in equal times; and that the periodic times of the different planets are in a certain given ratio to their distances from the sun. It is difficult to estimate the importance of these discoveries; either with reference to the amount of prejudice they overthrow, or their influence on astronomical theory. The circular and uniform motion of the celestial bodies was an axiom that had never been disputed. It was even admitted by Copernicus; who was obliged, in order to reconcile it with the observations, to suppose the sun placed at a little distance from the centre of each of the planetary circles. The elliptic motion was a proposition as bold as original; and, combined with the equal description of areas in equal times, led to the discovery of universal gravitation, and all the sublime results of physical astronomy.

About this time, or a little earlier, two discoveries were made which gave an immense impulse to astronomy. These were the logarithms, invented by Napier, and the telescope. Without the aid afforded by the logarithms, it would have been impossible to accomplish the calculations which Kepler's discoveries rendered necessary; and to the telescope we are indebted not only for the enlargement of the visible boundaries of the universe, and the knowledge of numerous bodies whose existence would otherwise never have been suspected, but also for all the precision of modern observation.

From the time of these great discoveries, the progress of astronomy has been uninterrupted. By combining the laws of the planetary motions discovered by Kepler, with the theory of central forces established by Huygens, Newton completed the theory; and proved that all the motions of the universe, from the fall of a body on the surface of the earth, to the oscillations of the celestial sphere, are the necessary consequences of a single, invariable, and simple law. This is the law of universal gravitation; which not only affords a physical explanation of all the phenomena that have been observed, but which, in the hands of mathematicians, has led to the discovery of many important facts which observation subsequently confirmed, though it could not have detected them. The progress of the practical parts of the science has, also, since the same epoch, been commensurate with the improvements of the theory. Observatories were established in different countries, where a continued series of observations has been kept up. Academies and societies were founded for the purpose of effecting, by combined efforts, what surpassed individual exertion; voyages and expeditions have been undertaken to distant parts of the world for the purpose of measuring the earth, and determining other elements necessary to a complete knowledge of the planetary system.

The state of perfection to which astronomy is now brought, may be regarded as the greatest triumph of human exertion and reason. The motions of the moon and the planets are known with the utmost accuracy; and the tables have all the precision which the navigator or practical astronomer can desire. Our knowledge of the planetary system may be regarded as complete. That

of the sidereal heavens must always be limited by the optical powers of the human eye and the telescope. In this department of astronomy, a boundless field has of late years been thrown open for future research and speculation. Stars are observed revolving about one another in elliptic orbits. Are they then connected with each other by forces of the same nature, and observing the same laws, as solar attraction? The periodic times, and consequently the mean distances of one or two comets, are observed to be diminished. Are we then to infer that the regions of space are filled with matter of sufficient density to resist the motions of comets? Are the comets themselves permanent bodies; or are they merely formed by the occasional collapse, as it were, of nebulous matter, and again dissipated after a few revolutions? The resistance of the ether, the nature of comets, the constitution of the nebulæ, the laws which regulate the formation and motions of sidereal systems: such are the questions (questions remote indeed from any practical application to the affairs of mankind) which astronomers now aspire to solve.

For further information on this extensive and very important science, we must refer the reader to the particular terms which belong to it, and also the general terms, COMET, MOON, PLANET, SATELLITE, STAR, SUN. The physical theory of the planetary motions will be found explained under GRAVITATION; and astronomical instruments described under their respective names. Works on astronomy are so abundant in every European language, that it could serve no purpose to make any references to them in this place. The best popular treatise is that of Sir John Herschel in Lardner's Cabinet Cyclopedia.

ASTA'RTE — the queen of heaven — a Phœnician goddess called in the Scripture Ashtaroth. There is some obscurity with respect to her worship, and the attributes assigned to her, which were held by different of the ancients, to correspond with those of the Grecian divinities Juno, Diana, or Venus, but most generally the latter. Indeed it is probable that the worship of this latter goddess was borrowed by the Greeks from that of Astarte, which prevailed to a great extent in the island of Cyprus, the fabled residence of Venus.

ASY'LUM. (Gr. ἀ, *not*, and συλάω, *I rob.*) A place of refuge to which criminals might fly, and from which it was considered the greatest impiety to move them by force. This privilege was given to many of the temples, altars, and statues of the gods, and its violation subjected the perpetrator, and all his posterity, to the vengeance of the tutelary deity, and consequently they were driven from their native country as accursed. The sacredness of the asylums was preserved till the reign of Tiberius Cæsar, who, on account of their inconvenience, abolished many, and restricted the privileges of the rest.

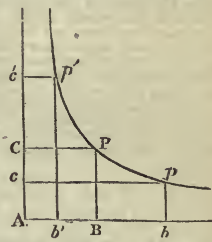
Thebes and Athens each claimed the establishment of the first asylum. Romulus set apart a particular spot on the descent from the Capitoline hill for this purpose, and thereby materially augmented the population of his infant city. Hence Juvenal satirically refers all the aristocracy of Rome to this ignoble stock:

> "Et tamen ut longe repetas, longeque revolvas
> Nomen ab infami gentem deducis asylo."

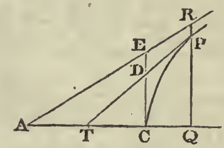
ASYLUM. The modern signification of this word differs widely from its ancient acceptation, and the purposes for which it is now employed will be best inferred from the epithets with which it is connected. The most prominent of these are asylums for the blind, deaf and dumb, lunatics, and the destitute. There is no feature, perhaps, which distinguishes a civilised from a savage state of society more than the establishment of institutions which tend to alleviate the condition of those whom moral or physical defects incapacitate for the purposes of self-exertion or competition with their fellow-citizens. In this view England has a right to claim a place in the foremost ranks of civilisation, whether we regard the number, the principles, or the internal management of its asylums. It would be out of place here to enter into detail upon so wide and comprehensive a question as the word asylum involves, but the reader will find in the parliamentary papers both of France and England, and in the reports published from time to time by the managers of asylums, a mass of information, on this subject, at once amusing and instructive.

ASY'MPTOTE. The name given to a straight line or curve which continually approaches nearer and nearer to the infinite branch of a given curve, in such a manner that when they are both indefinitely produced the distance between them, though it never entirely vanishes, becomes less than any assignable finite distance. The term, which was first employed by Apollonius, is derived from the Greek ἀ, priv., σύν, *with*, and πίπτω, *I fall*, and therefore signifies literally, *not coincident*, or that which does not meet.

Beginners feel some difficulty in assenting to the truth of the proposition that lines may continue to approach each other without meeting. It is, in fact, a proposition which cannot be made evident to the senses, but this arises from our inability to effect the division of magnitude beyond certain limits. A familiar instance of continual approach to equality is afforded by a repeating decimal; for instance, ·99999, &c.; the difference of which from unity is made ten times smaller by the addition of every successive digit; but it does not become equal to unity till the number of digits is supposed infinitely great. The nature and properties of an asymptote may be illustrated geometrically by the common hyperbola, the equation of which is $x\,y = a^2$. Let A B be the absciss, and A C the ordinate of any point P, and the parallelogram A P is equal to a constant quantity a^2. In like manner, the parallelograms made by the co-ordinates of any other points, p, p' will be each equal to a^2. It is evident, therefore, that the more the absciss A B is increased, the more the corresponding ordinate A C is diminished. If A b is equal to twice A B, then $p\,b$ is only half of P B, and so on. The curve, therefore, continually approaches to the axis of the abscissa, but never meets it; for supposing the point p to be taken at such a distance that A b would be a million of times greater than A B, $p\,b$ would be a millionth part of P B, — a small quantity, indeed, but still not zero. However great A p may be supposed, $p\,b$ must always have some value, otherwise a straight line would become equal to a parallelogram, which is impossible. It is obvious that all that has now been said of the axis A B applies equally to A C; therefore the two lines A B and A C are asymptotes to the curve.



The asymptotes of curve lines are most readily determined from the properties of their algebraic equations. Let us take, for example, the equation $B^2x^2 - A^2y^2 = A^2B^2$, which is that of the common hyperbola referred to its diameters. We easily deduce $y^2 = \frac{B^2x^2}{A^2}\left(1 - \frac{A^2}{x^2}\right)$ whence the absolute value of y is found, namely, $y = \frac{B}{A}x\sqrt{1 - \frac{A^2}{x^2}}$. But the quantity under the radical sign in this expression is always less than unity while x retains a finite value (for x cannot be less than A); the value of the ordinate y is therefore always less than $\frac{B}{A}x$. Now let a straight line A R be drawn through the centre A (the origin of the co-ordinates) making



with the axis an angle R A Q, whose tangent is equal to $\frac{B}{A}$; and let the ordinate P Q be produced to meet it in R, and let R Q be denoted by Y. We shall then have the two equations $Y = \frac{B}{A}x$, $y = \frac{B}{A}x\sqrt{1 - \frac{A^2}{x^2}}$; whence it is easy to see that the more x is increased, the more the difference between Y and y, that is R P, is diminished; and that it vanishes altogether when x is infinite.

The trigonometrical value of the cotangent of the angle P T Q, which a tangent at P makes with the axis, is $= \frac{A^2}{B^2}\frac{y}{x}$; or, substituting for y its value in terms of x, $= \frac{A}{B}\sqrt{1 - \frac{A^2}{x^2}}$ When the value of x is supposed infinite, this expression is reduced to $\frac{A}{B}$; consequently, the tangent of the same angle is $\frac{B}{A}$. But this is the tangent of the angle made by the asymptote; and hence the asymptote to a curve is frequently defined and considered as a tangent at an infinite distance.

In order to discover whether a curve has an asymptote, draw C E, meeting the tangent in D. In proportion as the point P is taken at a greater distance, the point T

approaches to A, and D to E. But the asymptote is the limiting position of the tangents; therefore we have only to find whether the expressions of C T and C D, relative to the given curve, are susceptible of finite limits, and when this is the case the construction of those limits will give the points A and E, and consequently the asymptote.

An algebraic curve cannot have more asymptotes than there are units in the exponent of its order. Of the curves of the second order, the hyperbola alone has asymptotes, and they are two in number. All curves of the third order, or which are defined by a cubic equation, have some infinite branches, but these branches have not always asymptotes. With respect to curves of the fourth order, there are an infinity of them which, so far from having four asymptotes, have none at all, and which have not even infinite branches; for instance, the curve of Cassini. The conchoid, cissoid, and logarithmic, though not classed among algebraic curves, have each an asymptote.

It may appear a sort of paradox that the areas bounded by curves and their asymptotes, though indefinitely extended, have sometimes finite limits which they cannot exceed. This is the case with the logarithmic curve, and with hyperbolas of all kinds, except the common or Apollonian.

In what precedes we have regarded an asymptote always as a straight line; but two curves are sometimes said to be asymptotes of each other when they are such that on being produced they continually approach without ever meeting. Thus two parabolas, having the same parameter, and their axes in the same straight line, fulfil the conditions of asymptotism.

ASYNARTE'TA. (Gr. ἀ, priv., and συναρτάω, *to connect.*) In Grammar, sentences which follow each other immediately, without the intervention of any connecting particle; as, "I came, I saw, I conquered."

ASY'NDETON. (Gr. ἀ, *without*, συνδέω, *I connect.*) A figure by which the conjunctions in a sentence are omitted: as in the famous phrase of Cæsar, "Veni, vidi, vici."

A'TE. (Gr. ἄτη.) In Greek Mythology, the personification of Revenge, Punishment, or Fatality. See Hom. Il. lib. xix.

A'TELES. (Gr. ἀτελής, *imperfect.*) A genus of South American monkeys, characterized by the absence or rudimental condition of the thumb of the anterior hands. The deterioration of these members as prehensile organs is compensated by a very efficient prehensile tail.

ATELLA'NÆ FA'BULÆ. A species of comedy which had its origin among the Oscan inhabitants of Campania, from a town of which country, Atella, it derived its name. It was much in vogue at Rome, and it was not thought disgraceful for persons of gentle blood to take parts in its exhibitions, as was the case in the other species of drama. The language used in the attellanæ fabulæ was Oscan, and the plots and style of the dialogue, unrestrained by any fixed rules, partook of the nature of comedy, farce, and burlesque, but was not stained by licentiousness, till the degenerate morals of the empire drew them too into the general vortex of corruption.

A TEMPO GIUSTO. (Ital. *in correct time.*) In music, a direction to the performer, generally after a recitative, to keep the measure true and correct, which, during the recitative, was performed to suit the action and passion of the scene.

ATHA'LAMOUS. (Gr. ἀ, *without*, and θάλαμος, *a bed.*) Lichens whose thallus is not furnished with shields or beds for the spores; in these the reproductive matter is supposed to be dispersed through the substance of the crust, as in lépraria.

ATHANA'SIAN CREED. A confession of faith, which is described in the rubric of the Common Prayer Book, which appoints it to be read on certain days, as commonly called the Creed of St. Athanasius. That it was really composed by that father is more than doubtful: modern divines seem generally to assent to the judgment of Waterland, who considers it to have been written by Hilary.

A'THEIST. (Gr. ἀ, *without*, and θεός, *God; without God.*) One who denies the existence of a God, or a Providence.

ATHENÆ'UM. (Greek.) In Antiquity, a public place where the professors of the liberal arts held their assemblies, the rhetoricians declaimed, and the poets rehearsed their performances. There were various places of this kind at Athens. The emperor Adrian established a famous Athenæum on the Capitoline hill at Rome, and at a later period there was another of nearly equal celebrity at Lyons. In modern times the name has been frequently bestowed upon establishments connected with learning, and upon public clubs or libraries frequented for convivial or literary purposes.

ATHERI'CERA. (Gr. ἀθὴρ, *a point*, κέρας, *a horn.*) The name given by Cuvier and Latreille to one of the primary divisions of the Dipterous order of insects. It comprehends the modern families *Syrphidæ*, *Astridæ*, *Conopidæ*, and *Muscidæ*, in all of which the antennæ have only two or three joints, the last being furnished with a bristle.

ATHERI'NA. A Linnæan genus of abdominal fishes, having an elongated body, two widely-separated dorsal fins, and a very protractile mouth armed with very small teeth. All the known species have a broad silvery band along each side, six branchiostegal rays. It was to the fishes of this genus that the ancients attributed an origin by equivocal generation; and the inhabitants of the shores of France, which are washed by the Mediterranean, still call them "nonnats."

ATHEROSPERMA'CEÆ. (Atherosperma, *one of the genera.*) Incomplete aromatic exogenous shrubs found in New Holland and South America, remarkable for having their flowers in a cup-shaped involucre, and the peculiar anthers of lauraceæ.

ATHLE'TES. (Gr. ἆθλον, *a prize.*) Men who contended at the public games of the Greeks and Romans, in boxing, wrestling, running, leaping, and throwing the quoit. The name was more particularly applied in the two former cases. Their dress consisted merely of a linen bandage round the loins, the rest of the body being left naked, and anointed with an unctuous mixture called ceroma. The boxers used a kind of glove called cæstus, which consisted of leather thongs wrapped round the hand with pieces of lead and iron sewed into them, to give greater weight to the blows.

Among the Greeks these contests were considered highly honourable, and the victors at their national games at Olympia, and elsewhere, were received in their native states with great distinction, and were rewarded with valuable privileges; indeed, one of their most popular divinities, Pollox, was celebrated for his skill in boxing. Among the Romans they were slaves, or hired persons of lower rank, or foreigners.

ATLA'NTES. (Gr. τλάω, *I bear.*) In Architecture, the statues of men used instead of columns to support an entablature. The word is used by Vitruvius.

ATLA'NTIDES. In astronomy, a name given to the Pleiades, because they were supposed to be daughters of Atlas, or his brother Hesperus, who were translated to heaven.

ATLA'NTIS. (Greek.) An island mentioned in Plato's Dialogue entitled Limæus, as having once existed in the Atlantic Ocean opposite to the Pillars of Hercules. It was said to have exceeded Europe and Africa jointly in magnitude; and after existing for 9000 years, during which period its inhabitants extended their conquests throughout the known quarters of the globe, to have been uprooted by prodigious earthquakes and inundations, and submerged in the ocean. The question of the reality and site of this island has been frequently discussed by modern geographers, who have displayed much critical perspicacity in its elucidation. M. Bailly supported the Platonic view of the existence and site of the island on the authority of the ancients, and cited Homer and Diodorus Siculus in corroboration of his opinion. Rudbeck, Kircher, Beckman, and others, concur in opinion respecting its reality, but each assigns to it a different locality. According to the conjectures of Buffon and Whitehurst, who regarded the Canaries and the Peak of Teneriffe as the summits of mountains belonging to some submerged continent, Atlantis was the land which, at a former period, united Ireland to the Azores and the Azores to America. On the other hand, D'Anville and Heeren regard Plato's account of the Atlantis as altogether a fanciful speculation; while there are not wanting many who discover in it proofs that the American continent was known at some remote period to the people of the Eastern hemisphere, but that the knowledge was subsequently lost.

A'TLAS, in Anatomy, is the term applied to the uppermost of the cervical vertebræ; so named from its supporting the head, as Atlas was supposed to support the globe.

ATLAS. In Literature, a name given to collections of geographical maps and charts; so called from the mythological giant who was said to support the globe. The name was first applied in this sense by Gerard Mercator, the geographer, in the 16th century. It is now used also for works in which other subjects are displayed in a tabular form: as, genealogy, chronology, ethnography, &c.

ATLAS. In Geography and Mythology, the name of an extensive chain of lofty mountains, some of their summits having an elevation of above 13,000 feet, in the N.W. of Africa. The early Phœnician and Greek navigators, who saw this vast chain from a distance, and were unacquainted with the intervening country, naturally formed the most extravagant notions of its height. This gave rise to a number of fables. The summits of the mountains were believed to pierce the skies; and the poets represented Atlas as an old man of gigantic stature who supported the heavens on his shoulders. Virgil has described Atlas, consistently with

the popular belief, in some of the finest lines of the Æneid : —

> ——— Jamque volans apicem et latera ardua cernit
> Atlantis duri, cœlum qui vertice fulcit ;
> Atlantis, cinctum assiduè cui nubibus atris
> Piniferum caput et vento pulsatur et imbri ;
> Nix humeros infusa tegit ; tum flumina mento
> Præcipitant senis, et glacie riget horrida barba. — IV. 246—252.

ATMO'METER. (Gr. ἀτμὸς, *vapour*, and μέτρον, *measure.*) An instrument for determining the rate of evaporation from a humid surface.

A'TMOSPHERE. (Gr. ἀτμὸς, *vapour*, and σφαῖρα, *a sphere.*) The assemblage of aeriform vapours which form the invisible medium which surrounds the earth. For an account of the different gases which enter into the composition of atmospheric air, see AIR. We shall here confine ourselves to an account of the mechanical properties of the atmosphere.

Weight of the Atmosphere. The first circumstance connected with the atmosphere which attracts our attention is its weight, or the pressure which it exerts on solid bodies at the surface of the earth. It is well known that the rise of water in the sucking pump, and the suspension of the column of mercury in the barometric tube, are caused by the pressure of the atmosphere ; we have therefore, in either of these phenomena, the means of exactly measuring its weight. The column of mercury in the tube of a barometer is exactly equal in weight to a cylinder of air of equal diameter reaching to the top of the atmosphere. Now, the mean height of the barometer at the level of the sea is about 28·6 inches ; and a cubic inch of mercury weighs 3425·92 grains, or 0·48956 lbs. avoirdupois. It follows, therefore, that a column of mercury whose base is a square inch, and height the mean height of the barometer, weighs $0·48956 \times 28·6 = 14·6$ lbs. avoirdupois nearly, or that the atmosphere exerts a pressure equal to 14·6 lbs. on every square inch at the surface of the earth.

This pressure of the atmosphere plays a very important part in the animal and vegetable economy. Like that of all other fluids, it is exerted equally in all directions ; thus the air in a tube presses not only on the bottom but also on the sides of the tube, with a force equal to 14·6 lbs. for every square inch. The surface of a man of ordinary stature is about 15 square feet, or 2160 square inches, whence the whole atmospheric pressure which his body sustains amounts to the enormous sum of 31,536 lbs. This great pressure is not sensible, because it is balanced by the reaction of the elastic fluids in the interior of our bodies ; but if the equilibrium were to be suddenly destroyed, the consequences might be fatal. Under the exhausted receiver of an air pump, animal life is soon destroyed : on the summit of a very high mountain a man experiences extreme fatigue, respiration becomes difficult, the pulse is accelerated, and it has happened that the blood has started from the eyes and ears, and other tender parts of the body, in consequence of the diminished pressure.

Density of the Atmosphere. The density of the atmosphere is not the same at different distances from the surface of the earth, but diminishes in the duplicate ratio of the altitude : that is to say, if at a certain altitude above the earth's surface it be one half what it is at the surface, then at twice that altitude the density will be only one fourth of what it is at the surface. This may be proved as follows. Conceive a vertical tube filled with air, reaching from the surface of the earth to the limits of the atmosphere ; it is evident that each particle of the inclosed air will sustain the pressure of all those above it ; and as the air, in consequence of its elasticity, is condensed proportionally to the pressure, it is easy to see that the density will go on diminishing from below upwards. To discover the law of this diminution, let x be the height of any point of this column above the surface of the earth, u = the density and p = the pressure of the air at x ; and in order to simplify the problem, we shall suppose the temperature to be the same throughout the column, and neglect the difference of pressure arising from the diminution of gravity. Supposing the area of the column = 1 the volume of an infinitely thin stratum is the differential of the height, or $d\,x$, and therefore the weight of all the strata or the whole column above the point x expressed by the integral $\int - u\,d\,x$ ($d\,x$ being taken with the negative sign, because when x increases the weight diminishes). But it is evident that the weight of the column above x must make an equilibrium with the pressure at x, therefore we have the equation $p = \int - u\,d\,x$. But the density is proportional to the pressure, therefore, A being a constant quantity, $p = A\,u$ and consequently $A\,u = \int - u\,d\,x$. Hence $A\,d\,u = - u\,d\,x$ and $d\,x = - A\frac{d\,u}{u.}$ Integrating this equation we get $x = C - A \log u$. Let U be the density at the surface, where $x = o$; the equation then becomes $o = C - A \log U$; whence eliminating C, $x = A \log U - A \log u$; or $x = A \log \frac{U}{u.}$ It follows therefore that as the altitude x increases, the logarithm of the density u diminishes ; whence we derive this important conclusion, that if the altitudes above the surface of the earth be taken in arithmetical progression, the densities of the air at these altitudes will be a geometrical progression decreasing.

By means of this theorem we can easily find the density of the atmosphere at different altitudes, with the help of a common table of logarithms. Suppose that at the height of one mile above the surface the density is represented by unity, the densities at other altitudes will be represented as follows : —

Height in miles	1,	2,	3,	4,	5,	6,	7.
Corresponding densities	1	0·739,	0·6309,	0·5011,	0·3981,	0·3163,	0.2511

So that at an elevation of seven miles the density is reduced to one-fourth, and at 14 miles to one-sixteenth, and so on. Conversely, when the variation of the density or pressure at different points is ascertained, the difference of altitude becomes known ; hence by means of the barometer we are enabled to ascertain the elevations of the different countries or mountains of the earth above the level of the sea.

Height of the Atmosphere. If the air were of the same density throughout, it would be very easy to determine the limits of the atmosphere. It has been found by accurate experiments, that at the temperature of 60° and under a pressure measured by 29·82 inches of mercury, a cubic inch of atmospheric air weighs 9·311446 grains. Comparing this with the weight of a cubic inch of mercury, it is found that if the density continued the same, the height of the atmosphere would be 328,021 inches, or 5·17 miles. But on account of the rapid diminution of the density, it is very evident that the height of the atmosphere must greatly exceed 5 miles, though we have no means of directly determining how much. There are, however, various methods of obtaining an approximate estimate. One of them, proposed by Kepler, is derived from observations on the twilight, which is occasioned by the power the atmosphere possesses of refracting and reflecting light. It is generally assumed that twilight ceases when the sun has descended 18° below the horizon. Now it may be considered that this takes place when a ray of light proceeding from the sun, and passing by the surface of the earth, just reaches the highest stratum of the atmosphere, and is reflected back to the earth in the direction of a tangent to its surface at the place of observation. On this principle it is calculated that reflection cannot take place at a greater altitude than 45 miles. There are other considerations which lead us to infer that the height of the atmosphere cannot be much less than this sum. With a good air pump, air may be rarefied 300 times ; supposing this to be the utmost limit to which rarefaction can be carried, the atmosphere would still extend to an altitude of about 40 miles.

Limits of the Atmosphere. Though we are unable to assign the precise boundaries of the atmosphere, there are phenomena which prove that it has a limit ; that it does not extend indefinitely into the celestial spaces, but belongs exclusively to our earth. If matter, or rather if atmospheric air, were infinitely divisible, the extent of the atmosphere would also be infinite ; but in this case the fluid could not be in equilibrio unless the sun and all the planets as well as the earth had respectively portions of it condensed around them proportional to their respective attractions. But it is known, from the phenomena of the eclipses of Jupiter's satellites, that the atmosphere of that planet does not by any means exceed that of the earth in proportion to the great superiority of his mass and attractive power ; hence there can be no communication between the atmosphere of the earth and that of Jupiter. It has also been shown by Dr. Wollaston, from phenomena attending the passage of Venus near the sun, that the sun has no sensible atmosphere. We are therefore warranted in concluding that the atoms of air are not infinitely divisible, and consequently that the atmosphere has a limit ; and the limit must be situated at that height above the earth where the gravitation of the atoms is just equal to the force of their repulsion.

Effects of the Atmosphere on Light. Like all other diaphanous substances, the atmosphere attracts the molecules of light, and deflects them from their rectilinear course. This phenomenon is called refraction. It increases the apparent elevation of all the celestial bodies above the horizon ; but, fortunately for astronomy, its effects can be rigorously calculated. The atmosphere also, notwithstanding its transparency, intercepts and reflects the rays of light, and multiplies and propagates them by an infinity of repercussions. If the atmosphere did not exist, objects would not be illuminated unless exposed to the direct light of the sun. As soon as we ceased to look at the sun, or objects illuminated by his rays, we should be left in total darkness. The solar rays reflected from the earth would be lost in the regions of space, and an excessive cold continually prevail. The

sun would continue to shine with unabated intensity, till it reached the horizon, and the transition from the glare of meridian splendour to absolute darkness would be almost instantaneous. All these effects may be judged of by what is experienced on the summits of very high mountains, where the air is greatly rarefied. The cold is insupportable. Scarcely any other light is received by the eye, than that which comes direct from the sun and the stars. The illuminating power of the atmosphere is so feeble, that to an eye placed in the shade the stars are visible in broad day.

Colour of the Atmosphere. The general blue colour of the atmosphere, and the brilliant and glowing tints of the morning and evening, arise from the different modifications which the different rays of light receive in passing through the air. When the sun is near the horizon, the stratum of air through which the light must pass before it reaches us is greatly thicker than when he is at a considerable altitude. Now the red rays possess a greater momentum than those of the upper portion of the spectrum, whence they force their way in greater abundance through the resisting mass of air, and penetrate to the earth, while the violet and blue are reflected or absorbed. Hence the ruddy colour of the morning and evening skies. The prevailing blue colour of the atmosphere is to be ascribed to the greater facility with which the blue and violet rays are reflected, or from possessing less power to penetrate through the aerial strata. At a great height in the atmosphere, the blue tinge disappears, and the sky becomes a deep black.

The atmosphere is a region of clouds and vapours through the agency of which the earth is fertilised and rendered fit for the support of animal and vegetable life. The various phenomena of which it is the theatre, and the effect of the changes which are continually taking place in its physical condition, form one of the most important branches of natural philosophy. (*See* CLIMATE, METEOROLOGY, VAPOUR, WIND, &c.)

Atmosphere, in Electricity, denotes a medium conceived to be diffused over the surface of electric bodies, and to extend to some distance from them. It is not proved that any such fluid medium exists, at least of a peculiar kind, though it figured greatly in the language of the early writers on electricity. Phenomena that were explained by the agency of a peculiar fluid, are now known to depend on the modification which common air receives from electric substances. *See* ELECTRICITY.

ATMOSPHE'RIC STONES. *See* AEROLITES.

ATMOSPHERIC TIDES. Certain changes in the barometric pressure of the atmosphere, depending on the attraction of the sun and moon. Laplace ascribes the lunar influence indicated by the observations on the diurnal variations of the barometer to the elevation and depression of the waters of the ocean, instead of the direct effect of the moon's attraction. The solar action he attributes wholly to the expansion caused by the heat of the sun. It is extremely doubtful if, in our latitudes, the attraction of the sun and moon produces any perceptible oscillation of the atmosphere.

A'TOM. (Gr. ἀ, *not*, and τέμνω, *I cut.*) A part so small as not to be divisible.

ATO'MIC THEORY. (In Chemistry.) When substances combine chemically, they are found to unite in certain weights; thus, water is constituted of one part by weight of hydrogen and eight of oxygen, and the gases only combine in those proportions to form it. It is assumed that water is a compound of an atom of hydrogen and an atom of oxygen, and that the relative weight of the atom of hydrogen to the atom of oxygen is as $1:8$; hence the atomic weight of water is $1+8$, or $=9$. The same theoretical views are applicable to all other simple and compound bodies, and the numbers which represent their combining weights are hence called their atomic or equivalent numbers. (*See* EQUIVALENTS, and AFFINITY.)

ATOMOGY'NIA. (Gr. ἄτομος, *uncut*, and γυνή, *a female.*) A word proposed to be substituted for angiospermia, the name of the second order of the sixth class of Linnæus, signifying that the ovary is not cleft into distinct parts.

ATO'NEMENT. (From the old English verb to atone, or reconcile: the phrase is still used adverbially, as where we say that two persons are "at one," i. e. agreed.) In Theology, the reconcilement of God with man by virtue of the death of our Saviour. The sacrifices of Jewish and patriarchal antiquity were types of this great event, and were in themselves offered for the purpose of atoning for sin; and the idea attached to the practice of sacrifice by the numerous heathen nations of antiquity, and of the present time, has always been the same. (*See* SACRIFICE.)

A'TRIUM. (According to Scaliger, from the Greek αἴθριος, *exposed to the air.*) In ancient Architecture, the atrium is by some considered the same as the vestibule, and Aulus Gellius intimates that in his time these two words were frequently confounded. There is reason for supposing that the vestibule was not properly a part of the house, but merely a portion of the entrance; for Cicero, in a letter to Atticus, describing the attack made on him in the via sacra, says, he took refuge to defend himself in the vestibule of Tatius. "Secessi in vestibulum Caii Tatii Domionis." If, however, in the time of Aulus Gellius these words were used ambiguously, it is not probable that at this period the question will be settled; and that this was the case is quite certain, for, in describing the spot where the colossal statue of Nero stood, Martial places it in the atrium, and Suetonius in the vestibulum. That the atrium was in an inner part the verse of Virgil, "Apparet domus intus et atria longa patescunt." According to the description of Vitruvius, it seems to have been a sort of covered portico, composed of two ranks of columns, forming a centre and two side aisles, and to have been beyond the cavædium or court, and before the tablinium or cabinet. The atrium was decorated with the statues of the proprietor's ancestors. Festus derives its name from its first use at Atria in Etruria. "Dictum atrium quia id genus edificii primum Atriæ in Etruria sit institutum."

A'TROPHY. (Gr. ἀ, priv., and τρέφω, *I nourish.*) A wasting away of the flesh.

ATRO'PIA. (Gr. ἄτροπος, *one of the Fates.*) A highly poisonous alkaline substance, extracted from the atropa belladonna, or deadly nightshade.

A'TTA. The name of a Fabrician genus of Hymenopterous insects belonging to the ant-tribe (*Formicidæ*), characterized by their very minute palpi, and the large size of the heads of the neuters. Some of the largest species of ant, as the visiting ant of South America, (*Formica cephalotes* L.), are included in this genus.

ATTA'CHMENT. In Law, a process issuing in a summary manner from a court of record against the person of any one guilty of a contempt of its rules. Attachment is most commonly granted against attorneys for malpractice, against sheriffs for making a false or no return to a writ, and against any parties neglecting to pay costs when ruled to do so.

Foreign Attachment. Under the custom of the city of London, whenever process for debt from the mayor or sheriffs' court is returned nihil, the plaintiff may, upon its appearing that a third person is indebted to the defendant, obtain satisfaction of his claim by attaching the debt. This is called foreign attachment.

ATTA'INDER, BILL OF. A species of extraordinary proceeding against parties accused of treasons or felonies which cannot be reached by the ordinary course of justice. During the reigns of the Tudors the more constitutional process of impeachment was entirely laid aside, and attainders were generally adopted in the case of state criminals. These bills usually commenced in the Lords. They have been very unusual in later times: the last recorded in Mr. Hatsell's Precedents of Parliament was directed against some persons concerned in the Scotch rebellion in 1746. Parliament is now bound, in passing these acts, to adhere to the rules of evidence which are followed in ordinary courts of justice.

Attainder is the supposed stain or corruption of the blood of a criminal legally condemned, which, by the common law of England, immediately follows the pronouncing sentence of death. The attainder of a criminal follows upon judgment, and not upon conviction. Attainder is either on appearance (by confession or by verdict) or by process, otherwise termed by default or outlawry, in case of non-appearance. For the effect of attainder on the lands, &c. of the criminal, *see* FORFEITURE. It is enacted by 54 G. 3. c. 145. that no attainder for felony, except in cases of high treason, petty treason, or murder, or abetting and counselling the same, shall extend to the prejudice of the rights of any persons except the offender during his life.

ATTE'LABUS. The name of a Linnæan genus of Coleopterous insects, characterised by moniliform antennæ, thicker towards the tip, and situated on the rostrum: the head pointed behind, and inclined. The species thus heterogeneously grouped together are now divided into the genera Attelabus proper, Apoderus, and Rhynchites. The latter includes some of the most beautiful weevils in this country, amongst which is the rare and splendid Carculio auratus.

ATTE'NTION. (Lat. *attentio.*) In Metaphysics, a steady exertion or application of the mind to any object of sense or intellect, in order to its being thoroughly understood, and afterwards retained. Attention is regarded by Stewart as a distinct faculty of the mind; and though this arrangement does not coincide with the views of many philosophers, his illustrations of the results or effects of attention are universally considered as a masterpiece of metaphysical disquisition. (Vide *Inquiry into the Human Mind*, ch. 2.)

ATTE'NUANTS. Remedies which dilute the blood.

ATTENUA'TUS. (Lat. *made thinner.*) When the thickness of any part diminishes in some particular direction, it is often used in the sense of narrowed, or angustate.

A'TTIC. (Gr. ἀττικὸς, *Athenian;* derived, in the seventh edition of "Ency. Brit.," art. "Architecture," from ἄτειχον, *without a wall*, which, if true, would make every thing attic

that was detached from a wall.) In Architecture, a low order of architecture, commonly used over a principal order, never with columns in it, but always antæ, or pilasters. It is employed to decorate the façade of a floor of small height, terminating the upper part of a building, and is doubtless called attic from its resemblance in proportional height and concealed roof to some of the buildings of Greece. Pliny describes it, after speaking of the other orders, thus: "Præter has sunt quæ vocantur atticæ columnæ quaternis angulis pari laterum intervallo." We, however, find no examples of square pillars in the remains of ancient art, though almost all the triumphal arches exhibit specimens of pilastral attics, having no capitals save the cornice breaking round them. In modern architecture the proportions of the attic order have never been subject to fixed rules, and their good effect is entirely dependent on the taste of the architect.

ATTIC BASE. *See* BASE.

A'TTICISM. (Gr.) An elegant or concise form of expression. Milton, in his Apology for Smectymnuus, thus uses it: "They made sport, and I laughed: they mispronounced, and I misliked; and, to make up the atticism, they were out, and I hissed." The term *Sal Atticum* was employed by the Romans at once to characterise the poignancy of wit and brilliancy of style peculiar to the Athenian writers, and to designate the liveliness, spirituality, and refined taste of the inhabitants of that city, which formed the focus and central point of all the eloquence and refinement of the Greeks.

A'TTITUDE. (Fr.) In Painting and Sculpture, the gesture and position of a figure, in which the action or sentiment of the person is represented. It should be natural and unconstrained, expressive, varied. Where more than one figure occurs there should be contrast in the limbs, and at the same time a balancing of each other.

ATTO'RNEY. (From the modern Latin torno, whence attorno, attornatus, signifying one who serves the *turn*, or is set in the place of another to do his business.) An attorney is either private or public. A private attorney is a person who acts for another in the conduct of his affairs out of court; for which purpose a verbal authority is in general sufficient; but for the performance of some acts, as, to deliver seisin of land, to transfer bank stock, or to execute a deed for another, he must be authorised by a formal power of attorney. He is not necessarily of the profession of the law; and the above, and all other the various matters unconnected with actual litigation in which he may be employed, such as the preparation of legal instruments, and the giving of advice and assistance in the transfer and management of property, may be undertaken by any other person. A public attorney, or an attorney at law, has been defined to be an officer of a court of record, legally qualified to prosecute and defend actions in courts of law on the retainer of clients. The circumstance of his being an officer of the court in which he may practise is important, as bringing him immediately within its summary jurisdiction, and thereby giving rise to his peculiar privileges and disabilities. A solicitor differs from an attorney in practising in courts of equity instead of common law.

Anciently parties were not allowed to appear in court by attorney without the king's special warrant by writ or letters patent, and if this could not be obtained were compelled every day during the pendency of their suit to be present in their own proper persons. The power of suing and being sued by attorney was first given by statute in the time of Edward I. All persons may now appear in court by an attorney of their own appointment, except infants, who must appear by next friend or guardian; married women, for whom, unless when proceeding in chancery in respect of their separate estate against their husbands, the attorney must be appointed by their husbands; idiots, and persons charged with any criminal offence, must appear in person; lunatics, if of full age, and corporations, cannot appear otherwise than by attorney.

The admission and practice of attorneys is now chiefly regulated by the 2 G. 2. c. 23., and other statutes made in the same and succeeding reign. The first requisite to be complied with in order to become an attorney is to enter into a contract in writing, called articles of clerkship, on which a heavy stamp duty is payable, with an attorney or solicitor actually practising, or other officer of court specified by statute to serve him in the capacity of clerk for five years. No attorney or solicitor can take more than two articled clerks at the same time, but some of the officers above referred to are allowed to take three persons who have taken the degree of B. A. or B. C. L. at Oxford, Cambridge, or Dublin, within a certain fixed period after matriculation at the university, and before execution of their articles may be admitted as attorneys after a clerkship of three years. Clerks also who are bound for five years are allowed to reckon as part of their term a year passed as bonâ fide pupils to a barrister or special pleader. After the expiration of the service, and notice given of his intention to apply for admission, the clerk must go before a board of examiners recently established by the judges under rule of court, and his fitness and capacity having been approved, be sworn in open court to demean himself honestly in his practice. His name is then entered on one of the records of the court, called the roll of attorneys, and he is duly admitted an attorney of that particular court. He may, however, when admitted of any one court at Westminster, practise in any one of the other courts there, in the name of an attorney of such other court, with his consent in writing. He may, at a trifling expense, be admitted a solicitor in any of the courts of equity, as a solicitor in equity may in like manner be admitted an attorney of any of the courts of common law. After admission he must, before the 16th December in every year, pay a certain duty, and obtain his certificate. Should he for one whole year neglect to take out his certificate, he would, besides incurring a penalty for practising without one, be thenceforth incapable of acting in court in any professional character; but upon payment of all arrears of duty since the expiration of his last certificate, and of a further sum by way of penalty, may be readmitted.

An attorney actually practising is supposed to be always present in court, and has for that reason many privileges in common with its other officers. He is accordingly exempted from serving on juries and inquests, and generally from filling all offices which require personal service; he has the privilege in all personal actions of suing in his own court, and of retaining the venue in Middlesex, and as defendant is not liable to be arrested on mesne process. He is in general privileged from giving evidence of any confidential communication made to him by his client: this, however, is the privilege not of the profession but of the client, who may waive it if he please. An attorney cannot fill the office of justice of the peace, sheriff, and many other offices, and cannot be bail for another unless in criminal cases. He is not permitted to deal with his clients in the same unrestrained manner in which ordinary men may deal with each other; and when a purchaser of his client's property, is sometimes required to show affirmatively in the first instance that he has given for it its full value. To restrain him from extortionate and vexatious conduct, he is required, one month at least before bringing an action to recover fees for business done in court, to deliver to his client a bill of costs, which, upon application of the client and his undertaking to pay what shall appear due, will be taxed by an officer of the court, and if exorbitant be reduced to a fair and reasonable amount. Where an attorney has been guilty of gross ignorance, neglect, or misbehaviour, in the management of his client's business, the court will frequently interpose in a summary manner, and compel the attorney to pay the costs, or make reparation for any loss occasioned by his default; and in cases of fraudulent malpractice grant an attachment against him, or even strike him off the roll. He is besides liable to an action for any gross and culpable negligence, by which the interests of his client may have been prejudiced. In matters of difficulty, not lying within his own department of the profession, he is protected from responsibility by acting on the opinion of counsel; but in matters of simple and ordinary practice, where the law will presume him to have the requisite knowledge himself, he cannot avoid his responsibility by consulting another.

ATTORNEY-GENERAL. An officer made by letters patent. He is the public prosecutor on behalf of the crown, his duty being to exhibit informations in criminal matters which concern the crown, ex officio, or by virtue of his office. (*See* INFORMATION.) He also files bills in the exchequer for any thing concerning the king's inheritance and profits, and bills are filed against him by others. The attorney-general has precedence of all other counsel. As chief legal adviser of the crown, in all matters falling within the purview of his office, his place is one of great importance, and is usually entrusted to new hands whenever an extensive change is made in the cabinet. It is generally understood that the attorney-general for the time being has a priority of claim for preferment to any of the high law offices which may fall vacant, if he is willing to accept it; but this rule has by no means been uniformly acted on.

ATTRA'CTION. (Lat. ad, *to*, and traho, *I draw*.) Used in physics to denote the tendency which we observe in certain bodies to approach one another, and to resist separation. The meaning of this term has been greatly obscured by metaphysical disputations. When a body A, is connected with another body B, by a rod, or chain, or in general by the intervention of any mechanical means, we see, or fancy we see, the reason why B attracts A, or A is compelled to follow the motions of B. But when two distinct bodies not connected by any visible bond of union are observed to aproach one another, the phenomenon seems to assume a greater degree of mystery, from our being no longer able to perceive any mode by which the one body can act on the other. On reflecting, however, on the constitution of material substances, and considering that they are composed of

distinct particles, which there are many reasons for believing are not in contact with each other, we may soon satisfy ourselves that there is, in reality, as much difficulty in conceiving how the different particles of a body cohere, or act on each other by impulse, as in conceiving how one body can be the cause of motion in another placed at a distance.

It is well remarked by Maupertuis, that the manner in which the different properties reside in a subject is always inconceivable to us. The vulgar are not astonished when they see a body in motion communicate its motion to other bodies; we are accustomed to the phenomenon, which prevents our perceiving in it any thing marvellous. But philosophers will not readily believe that an impulsive force is more conceivable than an attractive one. What, in fact, is this impulsive force? How does it reside in bodies? Who could have predicted its existence before seeing the bodies impinge on each other? The existence of other properties in bodies is not more clear. In what way does impenetrability and the other properties become joined to extension? In these things there will always be mysteries for us.

Before the time of Sir Isaac Newton, the term attraction was used to denote a species of quality inherent in certain bodies; at the present time, however, philosophers use the word not to express any particular mode or species of action, or any physical cause of such action, but simply the fact, that the different parts of matter tend to approach each other, without any reference to the question whether the power which produces that tendency is inherent in the bodies, or consists in the expulsion of an external agent. They regard it as one of the ultimate phenomena to which the analysis of matter leads. Newton himself particularly cautions his readers against supposing that there is really an attractive force residing in the centre towards which bodies tend, the centres being only mathematical points. He takes care to mention that he uses the term to denote a fact, and not a cause; that he used it only for the purpose of avoiding systems and explications; that this tendency might be caused by some subtle matter proceeding from bodies, and be the effect of a real impulsion; but whatever its cause might be, it was clearly a primary fact from which we might set out in explaining other facts depending on it. At present, objections of the sort which Newton here attempts to avoid, carry little weight with them, but in the time of Newton they were considered of the greatest importance. Leibnitz called attraction an occult quality, a term then held in horror; and the fact is certain, that the physical or metaphysical difficulties of explaining the nature of attraction contributed not a little to retard, on the Continent, the adoption of the Newtonian theory of the universe.

Attraction, with reference to the laws which it observes, may be divided into two kinds; one, taking place among bodies, placed at measurable distances from each other; the other among the small particles of matter, where the effect is only sensible at insensible or inappreciable distances. Among the instances of attraction at sensible distances, even at the greatest distances, the most remarkable is that of the attraction of gravitation, which belongs to all matter; which determines the motions and the figures of the planets and comets, and causes the descent of heavy bodies to the ground. For an account of the law which this species of attraction observes, and the astronomical phenomena which it produces, *see* GRAVITATION. The attraction of magnetism, of electricity, &c., are also instances of the action of bodies on each other, at sensible distances. *See* MAGNETISM; ELECTRICITY.

The second species of attraction exists only among the molecules or small particles of matter, and is hence called molecular attraction. The distances to which it extends are extremely small, or insensible. This species of attraction is the cause of the coherence of solids; of crystallisation; the refraction of light; the ascent of fluids in capillary tubes; the roundness of a drop of water; and in general, of all chemical actions. (*See* CAPILLARITY, COHESION, AFFINITY, &c.) It is to Newton that we owe the first distinct announcement of this last species of attraction, as it is to him that we owe the discovery of the law of the attraction of gravitation, and that it pervades celestial as well as terrestrial matter. The law of molecular attraction is not known; all that can be positively affirmed of it is, that it decreases in a much quicker ratio than the inverse square of the distance, and in many instances becomes prodigiously great, when the distance between the particles is diminished to its utmost limit.

It would not be possible to explain the constitution of matter, or account for the different forms under which it presents itself, by molecular attraction alone, without calling to aid the antagonist principle of repulsion. If the particles of matter only attracted each other, they would continue to advance nearer and nearer to each other, till further approach was rendered impossible by their impenetrability. But this does not take place; for all bodies are capable of contraction and dilatation, and in fact do dilate and contract, by the application of heat and cold. Thus, the particles of matter being solicited at the same time by two kinds of opposite forces, naturally assume that state of equilibrium which results from the compensated energies, and approach or recede, according as the attractive or the repulsive force predominates. All terrestrial phenomena depend on forces of this kind, as the celestial phenomena depend on universal gravitation. The repulsive force appears to be produced by the principle of heat: the attraction cannot be referred to any principle with which we are more familiar than we are with itself. Some philosophers have attempted to confound molecular attraction with the general attraction of gravity, or at least to regard the former as a modification of the other; but in the laws which they obey they are totally different.

Most of the disputes which have taken place about the nature of attraction have proceeded from the indistinct ideas which we attach to the term force. By force is meant the cause of motion; but we know not in general what that cause is; we only judge of its degree by the effect which we see produced. We have no means of measuring or comparing forces directly; what we do measure and compare are the changes of motion; and when we see bodies in motion, we immediately conclude that it is occasioned by the action of a force. Attraction and repulsion are principles of action; and if they are more difficult to be conceived than any other causes of action or motion, the obscurity arises merely from their implying action at a distance.

Of all the different kinds of attraction mentioned above, there is only one of which the laws have been fully investigated, namely, the attraction of gravitation. The electric and magnetic attractions are rather terms employed in physics for the purpose of giving a name to what we imperfectly understand, than used as principles from which to deduce the phenomena to which they give rise. The laws of capillary attraction have been investigated to a considerable extent by Laplace; but molecular attractions in general, which play so important a part in the economy of the world, have seldom been made the subject of mathematical investigation.

ATTRACTION OF MOUNTAINS. That power or force by which all the celestial motions are regulated, and to which we give the name of gravitation, does not act merely on the large masses of the universe; the smallest molecules of matter equally partake of its influence, and have an inherent and natural tendency to approach one another. This mutual action, in the case of small bodies, is insensible; because the attraction resulting from the whole mass of the earth absorbs, as it were, altogether, that which they exercise on one another; and renders their mutual approach infinitely small or imperceptible. But though the attractive force of matter is insensible in regard to small masses, it may become quite appreciable in the case of large mountains acting on the plummet of a delicate astronomical instrument. Newton himself was the first who deduced this consequence from his theory of universal gravitation. In his tract "De Mundi Systemate," § 22., he computes that a plummet, at the foot of a hemispherical mountain three miles high, and six broad (at the base), would be drawn about one minute and eighteen seconds out of the perpendicular. Some time elapsed, however, before any attempt was made to investigate the subject experimentally.

Those who are unaccustomed to consider the intimate relation that subsists among the different parts of physical science, and the light which the accurate solution of one question frequently throws on a multitude of others, will naturally inquire what useful purpose is to be gained by determining the attraction of a mountain, — a determination, moreover, of an extremely nice and delicate kind, and by no means easily executed. Nevertheless, the subject is one of very great importance in astronomy, and its investigation necessary, in order to ascertain the figure of the earth, and determine its interior density. The magnitude and figure of the earth are found by comparing the lengths of lines measured at different places on its surface with the corresponding celestial arcs, the extremities of which are the zenith points of the extremities of the terrestrial line. Now if, by the attraction of a mountain, or any other local cause, the plumbline is drawn aside from the perpendicular, or the direction of gravity is not perpendicular to the general surface, the position of the apparent zenith will be altered; and a very small deviation of this kind will produce a great error, for every second of the celestial arc corresponds to about 100 feet on the ground. It is necessary, therefore, to possess the means of making a correct allowance for such causes of local irregularity where they cannot be avoided. Again, the attraction of a mountain gives the means of determining the mean density of the earth. For suppose this attraction to be known by its effect on the plumbline, as the dimen-

sions of the mountain can be determined by measurement, and the density of its materials can in general be ascertained with tolerable accuracy, the quantity of matter which it contains becomes known. But the dimensions of the earth, and the amount of its attraction, are also known; therefore we are in possession of all the data necessary to enable us to compute its mean density.

There are various ways by which the quantity of the attraction of a mountain may be ascertained. One of the most obvious is to take two stations, one on the south and the other on the north side of the mountain, and as nearly as possible in the same meridian. From the zenith distances of the same stars observed at each station, the difference of their apparent latitudes may be accurately determined. But the real difference of the latitudes can also be determined by a trigonometrical measurement on the ground of the distance between the same stations. The difference of these determinations gives the sum of the deviations of the plumbline on the opposite sides of the mountain; and when divided in the inverse ratio of the squares of the distances of the stations from the centre of gravity of the mass, will give the deflection of the plummet at each station. Another method supposes one observer to be placed at the eastern foot of the mountain, and another at the western, having the means of accurately determining astronomically the difference of their meridians. This difference, compared with the measured distance by which the one station is east or west of the other, will show the effect of the attraction of the mountain; but as there is greater difficulty in determining accurately the difference of longitude than of latitude, this method cannot be so easily applied as the former. But it is not absolutely necessary, indeed it may be impracticable, to make observations on the opposite sides of the mountain. Let the meridian altitudes of the same stars be observed first on north or south sides of it, and then at a station on the same parallel of latitude, but at such a distance from the mountain as to be out of the reach of its action. The difference of the altitudes in the two cases will show the amount of the attraction of the mountain.

The first attempt to ascertain the attraction of a mountain by actual observation was made by the French academicians, Bouguer, Godin, and Condamine, who, about the year 1738, were dispatched to Peru for the purpose of measuring the length of an arc of the terrestrial meridian. Their experiments were made on the mountain Chimbaraço, the highest of the Cordilleras, and the result seemed to show that the zenith point was altered by the attraction of the mountain to the extent of about 7½ seconds of a degree. But this quantity was much too small to determine, with certain evidence, whether the mountain had or had not a sensible effect on the plumbline, for their instruments were not so perfect but that inconsistencies, amounting sometimes to upwards of 20 seconds, entered into their observations. From that time no farther attempt was made to determine this interesting fact in physical astronomy to the year 1774, when Dr. Maskelyne, the astronomer-royal at Greenwich, made an experiment of the same kind on the mountain Schehallien in Perthshire, with instruments capable of measuring the minute quantities in question. The difference of latitude of two stations on the north and south side of the mountain, compared with that which was inferred from the measurement of the distance on the ground, gave decidedly 5·8 seconds on each side, for the action of the mountain on the plummet of the zenith sector. The magnitude of the mountain was accurately measured at the same time; and with the data thus obtained a laborious calculation was made by Dr. Hutton, from which it resulted that the mean density of the earth is about five times that of water, or twice that of the ordinary rockstone near its surface. A third experiment of the same kind was made in 1810 by Baron Zach on the mountain Mimet, at a little distance from the shore of the Mediterranean near Marseilles. The instrument which he employed for determining the latitudes, a repeating circle of 12 inches radius, was much less to be depended on for accurate results than the zenith sector of Dr. Maskelyne; but in other respects his operations, particularly those connected with the terrestrial measurements, appear to have been conducted with far greater science and practical skill. The result was, that the deviation of the plumbline from the true vertical, caused by the attraction of the mountain, amounted to two seconds of a degree. Baron Zach did not attempt the further researches required for comparing the density on the mountain with that of the earth; such comparison, indeed, can only be made with respect to an insulated mountain, which Mimet is not.

Though the experiments hitherto made on this subject are few and imperfect, they are quite sufficient to establish the fact, that mountains are capable of producing sensible deflections of the plumblines of astronomical instruments. It is, therefore, of very great importance, in the measurement of degrees of the terrestrial meridian, to select for the station where the astronomical latitudes are observed, places remote from large mountains, and where the local irregularities of the surface are not very considerable. After every precaution of this sort has been taken, some uncertainty will still remain on account of local attraction; for it is obvious that a sudden and considerable variation of density in the strata under the surface will produce the same effect on the plumbline as a mass of matter elevated above it. To this cause is attributed, with much probability, a great part of the discrepancies among the results of the operations made to determine the figure of the earth, particularly among those for ascertaining the variations of density by means of the pendulum. See *Zach's Attraction des Montagnes*, Avignon, 1814. *Playfair's Works*, vol. iii. *Hutton's Tracts*, vol. ii. *Phil. Trans.* vol. lxviii.; also *Bouguer's Figure de la Terre.*

ATTRACTION, CHEMICAL. *See* AFFINITY.

A'TTRIBUTES. (Lat. ad, *to*, and tribuo, *I give.*) In the Fine Arts, certain symbols which are used to distinguish and characterise certain figures. Thus the eagle and thunderbolt are the attributes of Jupiter; the trident, that of Neptune; the caduceus, of Mercury; the bow and quiver attend Love; the balance and sword accompany Justice, &c. &c.

AUBAINE, DROIT D'. In French Jurisprudence, the right of the sovereign to the succession of a foreigner not naturalised, or of a naturalised foreigner dying intestate without heirs resident within the realm. The word is derived from the old French aubain, *foreigner:* said to come from the Latin alibi natus, *born elsewhere.* The droit d'aubaine still exists in various countries; and, although abolished at the Revolution, was restored by the Code Civil of Napoleon.

AUCHE'NIA. (Gr. αὐχήν, *the neck.*) In Mammalogy this term is restricted to the region of the neck, below the micha, or nape. Also, the name of a genus of Camelidæ, in which the above region of the neck is remarkably elongated.

AU'DITOR. One who examines and verifies the accounts of officers and others entrusted with money. The term is derived from the Latin audio, *I hear:* probably from the ancient practice of delivering accounts vivâ voce. Receivers-general of fee-farm rents, &c. are termed auditors. Officers with the same title are assigned by courts of law to settle accounts in actions of account, &c. The auditors of the exchequer were officers appointed to take the accounts of receivers of public revenues. The present board of commissioners for auditing the public accounts, exercising the duties formerly divided between various officers of the exchequer, was constituted in the year 1806. In Germany the junior legal functionaries are termed auditors. Its most usual sense seems to have been originally given to the word in France, where the members of the Chambres des Comptes were divided into conseillers-maîtres, and conseillers-auditeurs.

AU'GER. An instrument for boring the soil for the purpose of ascertaining the nature of the subsoil, the mineral, and, in agriculture more especially, the existence of water. There are various kinds of augers, according to the purposes to which they are to be applied; but they all consist of three parts, viz. the bit, mouth, or cutting piece; the handle; and the connecting rods. The handle is for the purpose of working the instrument by the means of two or more men: the rods for connecting the handle with the bit, or cutting piece; and the bit for penetrating the soil. When it is necessary to pass through stony soil or rocks, a chisel is substituted for the bit; and after the rock is broken in small pieces, the chisel is removed, and replaced by the common auger, by which the loose matters are drawn up.

AUGMENTA'TION, ARMS OF. In Heraldry, coats given by sovereigns to subjects as a mark of honour, to be quartered with their own; or charges, such as ordinances charged with some device, to be borne in their family shield. Such coats or devices are in general either significant, i. e. bearing some relation to the nature of the achievement for which the honour is bestowed; or they are portions of the royal arms.

AUGMENTATION OF STIPENDS. (Church of Scotland.) The stipends of ministers are under the control of the Court of Session. That court has the power to entertain applications for augmentation from clergymen, and either to grant or dismiss them. But twenty years must elapse before such application can be renewed.

AU'GSBURG, CONFESSION OF. A formulary drawn up by Luther and Melancthon, and presented to Charles V. at the diet held at Augsburg in 1530. It is adopted by the Lutheran church, but did not at the time succeed in comprehending all the reformers, and was the occasion of a separation between the followers of Luther and the party who called themselves the Evangelical Reformed Church, which has continued ever since.

AU'GURS. (Lat. augures.) Roman soothsayers, who professed to foretel events by the flying, singing, or feeding of birds. Their office was one of great importance in the state, as no enterprises or ceremonies were

performed unless they declared the omens favourable. Accordingly the members of their college were always elected from the most honourable citizens.

Their divinations were called auguries or auspices, between which there is sometimes a distinction made; the latter meaning such as were derived from the inspection of birds, the former being extended to all omens or prodigies whatever.

The Romans derived their knowledge of augury from the Tuscans, who were celebrated for their skill in this and other religious ceremonies.

AU'GUST. The eighth month of the year. The ancient Roman year commenced with March, and the sixth month was called Sextilis. The name was changed to August in compliment of Augustus Cæsar. In the calendar of Julius Cæsar, the distribution of the days through the several months was more commodious than the present arrangement. The first, third, fifth, seventh, ninth, and eleventh months consisted of thirty-one days each, and the other months of thirty, excepting February, which in common years contained twenty-nine days, but in leap years thirty. In order to gratify the frivolous vanity of Augustus, who thought it a disparagement that the month bearing his name should contain fewer days than July, which was named after the first Cæsar, a day was taken from February and given to August. Such was the origin of the capricious distribution of the days among the different months which now prevails over the whole Christian world; and which, being founded on no principle, requires some pains to be remembered.

AUGUSTA'LES. The epithet given to the priests or flamens of Augustus Cæsar. *See* FLAMEN.

AUGUSTA'LIS PRÆFE'CTUS. The præfect or governor of Egypt when it became a Roman province. This officer was a military viceroy appointed immediately by the emperor, and not selected from the senate, but from the order of knights; and he enjoyed greater power than the proconsuls and proprætors, under whose care the other provinces fell. The epithet Augustalis was derived from the circumstance of Augustus having appointed the first præfect of Egypt.

AUGUSTA'LIA. A festival instituted in honour of Augustus Cæsar on the occasion of his pacifying Sicily, Greece, Syria, Asia Minor, and Parthia.

AUGU'STAN HISTORY. A series of history of the Roman empire from the year 157 A. D. to 285 A. D., written by the following six authors: Æl. Spartianus, J. Capitolinus, Æl. Lampridius, Vulcatius Gallianus, Trebellius Pollio, and Flavius Vopiscus.

AUGU'STINE AGE. A term used to designate the reign of Augustus, the most brilliant period in the literary history of Rome. The civil wars that had long distracted the Roman empire had stifled the cultivation of literature and the arts; and when the battle of Actium had terminated internal commotion, nothing, it was supposed, could so effectually celebrate and adorn the restoration of peace and the happy reign of Augustus, as the appearance of great national poets, who might supply the chief defect in the literature of their country, and create a body of classical works, in which the ancient Roman traditions might be transmitted to posterity. To accomplish this object, men of genius were flattered, courted, and enriched, in an unexampled manner, by the liberality of Augustus; and after a brief interval, the verses of Virgil, Horace, Propertius, Ovid, and Tibullus resounded throughout the empire in their respective epic, lyric, and elegiac strains. But it was not merely for ornamental literature that the age in question was distinguished. The science of jurisprudence, the only original intellectual possession of great value to which the Romans can lay undisputed claim, then received its full development: the immense and nearly inexplicable masses of Roman statutes were perspicuously arranged; and the boundaries of strict law on the one hand, and equity on the other, were respectively ascertained. In this age, too, Rome became the seat of universal government and wealth; and so numerous and splendid were the architectural decorations with which it was embellished, as to justify the saying of Augustus — that he found Rome of brick, and left it of marble.

AUGU'STINE. In Ecclesiastical History, an order of monks and nuns established in the eleventh century, apparently in commemoration of the monastic societies assembled by Saint Augustine in the fourth, but which had long ceased to exist. *See* ORDERS, ECCLESIASTICAL.

AU'LIC COUNCIL, or REICHSHOFRATH. A council of high powers and dignity in the German empire. The Aulic Council and Imperial Chamber (reichskammergericht) were the two supreme courts in that empire. The former consisted of a president, vice-president, and eighteen councillors, six of whom were Protestants, with the peculiar privilege that, if unanimous, their votes could not be overruled by those of the Catholics. This court had exclusive jurisdiction in various affairs, principally those which concerned the imperial government.

AULO'STOMA. (Gr. *αὐλὸς, a pipe, στόμα, a mouth.*) A genus of Acanthopterygians belonging to the family called by Cuvier *Bouches en flute;* including the pipe-fishes, or those species which are characterised by a mouth which is lengthened into a kind of tube or pipe.

AU'RA. (Lat. *the air.*) The subtle essence which is contained within the grains of pollen, and in which is supposed to reside the power of fertilising the ovules. It is now generally considered that this essence is imaginary, and that fertilisation is produced by the descent of minute organic particles through the stigma to the ovules.

AURA. A sensation resembling a wind, or being breathed upon. *Aura epileptica* is a sensation often experienced by epileptic patients, resembling the ascent of a blast of cold air from the extremities upwards.

AURANTIA'CEÆ. (Lat. aurantium, *an orange.*) A considerable natural order of Exogens, with polypetalous flowers, confined to the warmer parts of Asia, or the nearest parts of Africa. They have dotted leaves filled with a fragrant oil, and succulent eatable fruit, covered by an aromatic skin. The orange, the shaddock, the lime, the lemon, are all species of the genus Citrus, and the best known in Europe. In the woods of India, there are some species that climb; and in the Himalaya exists a species, Limonia laureola, which would probably be a hardy evergreen if introduced into this country.

AURE'LIA. In Entomology, the name given to the nymph, or quiescent stage of transformation of an insect, on account of the metallic golden lustre which is reflected from the case of the nymphs of some diurnal Lepidoptera.

AURE'OLA. (Lat. *of the colour of gold.*) In Painting, the glory with which the ancient painters decorated the heads of the saints, martyrs, and confessors which they executed.

AU'REUS. A Roman gold coin worth a little more than sixteen shillings, according to the proportion given by Tacitus. But it varied, as appears from the different values assigned to it, from 1*l.* 4*s.* to 12*s.* Its weight was about 2½ oz. avoirdupois.

AU'RICLE. (Lat. auricula, *a little ear.*) Signifies, in Mammalogy, the external ears, which are said to be 'marginate' (*auriculæ marginatæ*) when bordered by a helix, or involute margin; — to be 'operculate' (*auriculæ operculatæ*) when provided with a largely developed tragus, which stands out like a subsidiary auricle; — to be 'concealed' (*auriculæ absconditæ*) when covered by the hair. In Ornithology, the circle of feathers surrounding the entry to the ear-passage are called auriculars. In Anatomy, the venous chambers of the heart are termed auricles.

AURI'CULAR CONFESSION. Confession of sins to a priest in private, distinguished from the public confession which was enjoined as a duty by the primitive church, but was early allowed to drop into disuse. It was on occasion of the scandal which the original practice produced, that Leo the Great, in the fifth century, first recommended private confession to a priest in certain cases. It was not till the fourth council of Lateran in 1215, that the doctrine of the necessity of this practice was formally established.

AURI'CULATE. (Lat. auricula, *a little ear.*) When the base of a leaf or similar part projects on each side of the axis in the form of a little round lobe.

AURO'RA. In the ancient Mythology, the goddess of the morning. She was the daughter of Titan and Terra, and was deified as the light which precedes the rising of the sun above our hemisphere. So lovely a being as she was represented to be could not fail to attract a host of admirers; and, accordingly, we find her engaged in numerous amours. But the object of her peculiar favour was Tithonus, son of Laomedon, king of Troy, for whom she cherished so permanent an attachment as to obtain for him the gift of immortality. She unfortunately neglected, however, to combine this privilege with an immunity from age; and in the course of time Tithonus became so decrepid that Aurora out of pity transformed him into a grasshopper, in which shape he still retained the garrulity of old age. She is supposed generally to rise from the couch of Tithonus: —

> Et jam prima novo spargebat lumine terras,
> Tithoni croceum linquens Aurora cubile. — VIRG.

Milton, in a passage teeming with poetic imagery and truth, thus opens the fifth book of Paradise Lost: —

> Now Morn, her rosy steps in th' eastern clime
> Advancing, sowed the earth with orient pearl;
> When Adam waked, so customed, for his sleep
> Was aëry, light, from pure digestion bred
> And temperate vapours bland, which th' only sound
> Of leaves and fuming rills, Aurora's fan,
> Lightly dispersed, and the shrill matin song
> Of birds on every bough.

AURO'RA BOREALIS. *Northern lights, Polar lights,* or *Streamers.* A luminous meteor, generally appearing in the northern part of the sky, and presenting a light somewhat resembling the dawn or break of day. The appearances which it exhibits and the forms it

assumes are so proverbially unsteady, that it is not possible to comprehend them under any general description. Most frequently the phenomenon appears to proceed from a sort of horizontal cloud or haze in the northern part of the sky, rising a few degrees above the horizon, and stretching from the north towards the east and west, so as to form an arc, which in some instances has been observed to extend upwards of 100°. The upper edge of the cloud is whitish and luminous, the lower part often dark or thick, and sometimes the clear sky may be seen between it and the horizon. From the upper part of the cloud streams of light shoot up in columnar forms, reaching sometimes only a few degrees, sometimes to the zenith, or even beyond it. Instances occur in which the whole hemisphere is covered with coruscations; but the brilliancy is greatest, and the light strongest, in the north near the main body of the meteor. The streamers have in general a tremulous motion, and, when close together, present the appearance of waves or sheets of light following each other in rapid succession. When several columns, issuing from different points, meet at the zenith, a small meteor is formed of greater brilliancy than the separate columns. The phenomenon sometimes continues a few hours, occasionally the whole night, and even for several nights in succession. It generally commences at most two or three hours after sunset, and very rarely in the morning or much after midnight. Auroras have been observed even before the evening twilight has disappeared. In the Shetland Islands, and other countries in high latitudes, the northern lights are the constant attendants of clear and frosty evenings in winter. They are most frequent in autumn.

In Captain Franklin's Narrative, the Auroras observed at Fort Enterprise, in North America, are described by Lieut. Wood as follows:—

"They rise with their centres sometimes in the magnetic meridian, and sometimes several degrees to the eastward or westward of it. The number visible seldom exceeds five, and is seldom limited to one. The altitude of the lowest, when first seen, is never less than 4°. As they advance towards the zenith, their centres (or the parts most elevated) preserve a course in the magnetic meridian, or near to it. But the eastern and western extremities vary their respective distances, and the arches become irregularly broad streams in the zenith, each dividing the sky into two unequal parts, but never crossing one another till they separate into parts. Those arches which were bright at the horizon increase their brilliancy in the zenith, and discover the beams of which they are composed, when the interior motion is rapid. This interior motion is a sudden glow, not proceeding from any visible concentration of matter, but bursting out in several parts of the arch, as if an ignition of combustible matter had taken place, and spreading itself rapidly towards each extremity. In this motion the beams are formed. They have two motions; one at right angles to their length, or sideways; and the other a tremulous and short vibration, in which they do not exactly preserve their parallelism to each other. The wreaths, when in the zenith, present the appearance of coronæ boreales. The second motion is always accompanied by colours; for it must be observed, that beams are often formed without any exhibition of colours, and I have not in that case perceived the vibratory motion."

The northern lights are sometimes seen tinged with the various prismatic colours, among which orange and green, but more frequently the different shades of red, predominate. Maupertius describes one seen by him in Lapland, by which an extensive region of the heavens towards the south appeared tinged of so lively a red that the whole constellation of Orion seemed as if dyed in blood. Some observers of this meteor have affirmed that they have heard a rustling or crackling sound proceed from it. Doubts have, however, been entertained on this point, from the circumstance that no such noises were heard by Scoresby, Richardson, Franklin, Parry, and Hood, who observed the polar lights with great care, under the most favourable circumstances, in very high latitudes. But the testimony of other observers is of so positive a kind as to leave no reasonable doubt that the phenomenon has, at least in particular instances, been accompanied by sounds.

From the accounts which have been collected of the polar lights, it would seem that the phenomenon was less frequent in former ages than it is now; but it must be kept in mind that meteoric observations have not always been so much attended to as at present. Aristotle describes the phenomenon with sufficient accuracy in his book of Meteors. Allusions are also made to it by Pliny, Cicero, and Seneca; so that it must have been often witnessed by the ancients, even in the climates of Greece and Italy. The descriptions of armies fighting in the air, and similar prodigies observed in the dark ages, doubtless owed their origin to the striking and fantastic appearances of the Northern Lights. It is remarkable, however, that no mention is made by any English writer of an Aurora Borealis having been observed in England from the year 1621 to 1707. Celsius says expressly that the oldest inhabitants of Upsala considered the phenomenon a great rarity before 1716. In the month of March in that year a very splendid one appeared in England, and by reason of its brilliancy attracted universal attention. It has been described by Dr. Hally in the Phil. Trans., No. 347. Since then, the meteor has been much more common. A complete account of all the appearances of Auroras recorded previous to 1754 may be found in the work of Mairan, "Traité de l'Aurore Boreale."

The Aurora is not confined to the Northern hemisphere, similar appearances being observed in high southern latitudes. An Aurora was witnessed by Don Antonio d'Ulloa at Cape Horn in 1745; one appeared at Cuzco in 1744; and another is described by Mr. Forster (who accompanied Captain Cook in his last voyage round the world), which was seen by him in 1773, in latitude 58° south, and resembled, entirely, those of the northern hemisphere, excepting that the light exhibited no tints, but was of a clear white. Similar testimony is given by subsequent navigators.

There is great difficulty in determining the exact height of the Aurora Borealis above the earth, and accordingly the opinions given on this subject by different observers are widely discordant. Mairan supposed the mean height to be 175 French leagues. Bergman says 460 miles, and Euler several thousand miles. From the comparison of a number of observations of an Aurora that appeared in March 1826, made at different places in the north of England and south of Scotland, Dr. Dalton, in a paper presented to the Royal Society, computed its height to be about 100 miles. But a calculation of this sort, in which it is of necessity supposed that the meteor is seen in exactly the same place by the different observers, is subject to very great uncertainty. The observations of Dr. Richardson, Franklin, Hood, Parry, and others seem to prove that the place of the Aurora is far within the limits of the atmosphere, and scarcely above the region of the clouds; in fact, as the diurnal rotation of the earth produces no change in its apparent position, it must necessarily partake of that motion, and consequently be regarded as an atmospherical phenomenon.

No satisfactory theory has yet been given of the cause of the polar lights. Mairan ascribed the phenomenon to the sun's atmosphere; Euler, to particles of the earth's atmosphere driven beyond its limits by the impulse of solar light. Beccaria, Canton, Franklin, and others refer it to electricity, an agent to whose mysterious influence all the inexplicable phenomena of meteorology are conveniently ascribed. An absurd theory proposed by M. Libes (Dictionnaire de Physique) formerly met with considerable favour. He had observed that on passing an electric spark through a compound of oxygen and nitrogen, nitrous vapours of a reddish colour are produced. He therefore supposed that the higher regions of the atmosphere near the pole contain little or no hydrogen; and that consequently the discharges of electricity, which, by producing a combination of oxygen and hydrogen, form water in the lower strata, in the more elevated strata produce nitrous vapours, which constitute the polar lights. That some connexion subsists between the Aurora and magnetism, or rather electricity, which is now regarded as the primary cause of magnetism, is made certain by the fact that during the continuance of brilliant Auroras the magnetic needle is generally disturbed, sometimes violently agitated. The air at the same time is often observed to be highly charged with electric matter. An experiment contrived by M. Canton also seems to indicate an electric origin. If a glass tube be partially exhausted of air, hermetically sealed, and applied to the conductor of an electric machine, the whole tube is illuminated from end to end, and continues luminous for a considerable time after it has been removed from the conductor. If, after this, the tube be drawn through the hand, the light will be remarkably intense through its whole length; and if it is grasped in both hands, near the extremities, strong flashes of light will dart from one end to the other, and continue many hours without fresh excitation. The only conclusion which, in the present state of our knowledge, we are warranted in deducing, is, that the Aurora Borealis must be ascribed to the agency of electricity in the upper regions of the atmosphere: in what way the excitement is produced, it remains for future discoveries to make known.

The most systematic series of observations which we possess on the subject, was made by the Rev. James Farquharson, of Aberdeenshire, in 1829, with an apparatus furnished by the Royal Society, and of which an account is published in the Transactions for 1830.

AU'RUM MUSIVUM. An obsolete chemical name of the bisulphuret of tin.

AU'SPICES, AUSPICIA. *See* AUGURS.

AUSCULTA'TION. (Lat. auscultare, *to listen.*) A method of distinguishing healthy and diseased states of the body by the study of the sounds produced by the movements of the different organs, and which differ more

or less when the parts are diseased from those which belong to their healthy functions. *See* STETHOSCOPE.

AUTHE'NTIC, AUTHENTICATED. A word of Greek origin. In Diplomatics, ancient MSS. were formerly termed authentica when originals, in opposition to copies. In the modern acceptation of the word, it is only applied to instruments bearing marks of having been executed by the proper authority.

AUTHENTIC MELODIES. In Music, such as have their principal notes contained between the key note and its octave. This term is applied by the Italians to four of the church modes or tones in music which rise a fourth above their dominants, which are always fifths above their finals, that is, rise to complete their octaves, thus distinguished from plagal melodies, which fall a fourth below their finals.

AUTO-DA-FE, properly AUTO-DE-FE. (Span. *act of faith.*) A public solemnity held by the Court of the Inquisition in Spain and Portugal. It was a gaol-delivery, at which extracts from the trials of offenders, and the sentences pronounced by the judges, were read; after which, absolution was conferred on those who were penitent, and discharged: after which, those condemned to death (relajados) were transferred to the secular authority: and here the auto, properly so called, ended; the execution of the victims taking place immediately afterwards, under the authority of the civil judge, a secretary to the inquisition attending. The ceremonial of the autos, processions, horrible executions, &c., are amply described by many writers. See especially *Llorente's History of the Inquisition; A Relation of the Inquisition in Portugal*, published by Bishop Burnet; and *Olmo's Account of the Senual Auto-da-Fe at Madrid* in 1680, from which the account in the Penny Cyclopædia is abridged. Autos were of several sorts: the public general act (auto publico general), to which the above descriptions apply; the particular act, at which only the officials of the inquisition were present; autillo, or little act; and auto singular, the condemnation of a single individual. *See* INQUISITION.

AUTOBIO'GRAPHY. (This word is of Greek origin, and signifies literally *the life of a person written by himself.*) One of the most fascinating, and, if properly understood, one of the most instructive, species of composition. But none is more calculated to mislead the incautious reader, or to give more false impressions, both of men and events. These memoirs may be divided into two classes: those in which the chief object of the writer is to illustrate the history of his own mind and heart, and the manner in which these were swayed by the destinies of his life; and those in which his purpose is merely to give a sketch of the scenes and events which have occurred within his own experience, and of characters with which he has been brought in contact. Of the first class of writings, from the Confession of Saint Augustine down to the Confessions of Rousseau, and the many works which have since been produced in imitation of the latter, it may be said that the general defect is a morbid spirit of exaggeration. The mind dwells with intense recollection on its own pains and pleasures, errors and victories; it magnifies contrasts, paints every thing in extrêmes, and leaves out of the portrait all neutral and moderate features, because the recollection of ordinary feelings and actions passes away, while that of strong excitement is indelible. Of the more narrative class of memoirs, it is sufficient to say, that where the writer was himself a prominent actor in passing events, they are usually little better than apologies or self-justifications, such as the famous Memoirs of the Cardinal de Retz, and, in our own times, the various fragments of autobiography which have been published from the hand of Napoleon.

AUTOCA'RPIOUS. (Gr. αὐτὸς, *himself*, and καρπὸς, *fruit.*) A name given to such fruit as consists of nothing but pericarp, without any additional organ, such as the calyx adhering to the outside.

AUTO'CHTHONS. (Gr. αὐτὸς, *self*, and χθὼν, *earth.*) The Greek term for the aboriginal inhabitants of a country, implying that they were sprung from the soil. The Athenians, whose territory had been held by the same race from time immemorial, chiefly on account of its sterility, which offered no incitement to foreign aggression, particularly laid claim to this title, in memorial of which they wore the emblematic grasshopper as part of their head-dress.

AU'TOCRAT. In Politics, a word derived from the Greek αὐτοκράτωρ, *sole* or *independent governor.* This title of Autocrator was given to Athenian generals invested with full command by the republic; also to envoys, in which case it corresponded in meaning with the barbarous Latin word plenipotentiaries. In modern political phraseology, the term autocrat, signifying a sovereign possessed of absolute power, is usually confined to the emperor of Russia.

AU'TOGRAPH. (Gr. αὐτὸς, *self*, and γράφω, *I write.*) The autograph of an individual is a piece of writing in his hand.

AUTO'MATON. (Gr. αὐτὸς, *self*, and ματῆν, *easily.*) A name applied to pieces of mechanism so constructed as to imitate the actions of living animals. The term Android (from the Gr. ἀνὴρ, *man*) is sometimes applied to such machines as resemble the figures and imitate the actions of mankind.

The extent to which these useless but ingenious contrivances has been sometimes carried is very surprising. Archytas of Tarentum, about 400 years before our era, is said to have made a wooden pigeon that could fly. Friar Bacon's speaking head is a well-known tradition. Albertus Magnus constructed an automaton to open his door when any one knocked; the celebrated Regiomontanus, a wooden eagle that flew forth from the city, saluted the emperor, and returned; and likewise an iron fly which flew out of his hand, and returned after flying about the room. These instances may perhaps have been exaggerated in the description; but there are some of recent date, and not less remarkable, respecting which the testimony is clear and strong. The following are a few of the best authenticated: — The flute-player of Vaucauson, described by D'Alembert in the *Encyclopedie Methodique*, was exhibited in Paris in 1738. It played on the flute exactly in the same manner as a living performer, and commanded three octaves, the fullest scale of the instrument. Its height was nearly six feet. In Hutton's *Mathematical Recreations*, a description is given of an automaton group, constructed by M. Camus for the amusement of Louis XIV., consisting of a coach and horses, with coachman and page, and lady inside, &c., by which the action of driving up, alighting, presenting a petition to the king, and setting off again, were mimicked with wonderful accuracy. In 1741, Vaucauson produced a flagelet-player, which played the flagelet with the left hand, while it beat a tambourine with the right. He also produced a duck, which dabbled in the water, swam, drank, and quacked like a real duck; raised and moved its wings, dressed its feathers with its bill, took barley from the hand and swallowed it, and even digested its food by means of materials for its solution placed in the stomach. (Montucla, *Histoire des Math.*, tome iii. p. 802.)

Automaton flute-players have likewise been exhibited in this country, of the size of real life, which performed ten or twelve duets. Maelzel, the inventor of the metronome, exhibited an automaton trumpeter at Vienna, of which a description is given in the *Journal des Modes* for 1809. It was a martial figure, in the uniform of a trumpeter of an Austrian dragoon regiment, which played not only the Austrian and French cavalry marches, and all the signals of those armies, but also a march and an allegro, by Weigl, accompanied by the whole orchestra, &c. (*Dictionary of Musicians*, London, 1827.)

Automata have also been constructed which wrote, drew likenesses, played on the pianoforte, &c. The celebrated chess-playing automaton is now considered as a solved mystery, it being supposed (and not denied) that a boy was concealed inside the figure. The machinery, however, which produced such motions must have been highly ingenious. See *Penny Cyclopædia; Hutton's Math. Dictionary; Encyc. Brit.*, article "Androides."

AU'TOPSY. (Gr. αὐτὸς, *self*, and ὄψις, *sight.*) Ocular evidence.

AU'TUMN. The third of the four seasons of the year. In a popular sense it denotes that period of the year in which the fruits of the earth are gathered in. Astronomically speaking, it is the time during which the sun is passing from the autumnal equinox to the winter solstice. Owing to the elliptic form of the earth's orbit, the seasons are not all of the same length; and owing to the precession of the equinoxes, their lengths vary a little from age to age. In the present century, the time which elapses between the sun's passage through the autumnal equinox and his reaching the winter solstice, or while he passes through the three signs of Libra, Scorpio, and Sagitárius, is 89 days 16 hours and 47 minutes. The autumn of the northern hemisphere corresponds to the spring of the southern.

AUTU'MNAL EQUINOX. The day on which the sun passes through the equator, going southward, or on which his declination changes from north to south. When the sun is in the equator, the day is equal in length to the night all over the world. *See* EQUINOX. The autumnal equinox falls generally on the 22d or 23d of September.

AUTU'MNAL POINT. One of the two points in which the ecliptic intersects the equator. It is the same as the first point of the sign Libra.

AVALA'NCHES. Masses of snow which collect upon the heights of mountains, and gradually sliding down their sides, acquire enormous bulk by fresh accumulations: when they ultimately reach the valleys below, they often cause great destruction.

AVA'ST. A sea term, signifying, enough; stop; cease. The etymology of this word is doubtful.

AVELLA'NA. (Abella or Avella, *a town of Campania, celebrated for its fine filberts.*) One of the names of the common hazel nut. The Spaniards in Chili apply

the name to the fruit of Quadria heterophylla, because of its resemblance to filberts.

AVENA SATIVA. (Diandria trigynia *Lin.*, Gramineæ *Juss.*) The Linnean name of the common oat. A gramineous plant characterised by a loose compound equal panicle and two-flowered spikelet. The oat is very extensively cultivated in most of the northern countries of Europe as a bread corn. It has long occupied the same place in Scotland that rye occupies in Germany and the potatoe in Ireland. In England it is chiefly used in the feeding of horses; but there, also, it is used to a considerable extent as food for man, particularly in the northern counties. There are three leading varieties of the common oat cultivated in England — black; grey, dun-brown, or red; and white. The first two varieties being comparatively hardy, may be raised on very inferior soils, and in situations unsuitable for the other. The black oat is now, however, hardly known in England; but it is still cultivated to a considerable extent in some parts of the Highlands of Scotland, and in the Western Islands. The dun or red oat is principally confined to the moors of Cheshire, Derbyshire, and Staffordshire. White oats are, speaking generally, less hardy than either of the other varieties, and require a better soil; but they are also earlier, heavier, and yield a greater quantity of meal. There are numberless, and some widely different, sub-varieties of the white oat. That which is called the potatoe oat has long enjoyed the highest reputation in this country, and is almost the only variety that is at present raised on good land in most parts of England and the south of Scotland. The produce of oats varies very greatly. When the ground is foul or exhausted, not more than 20 bushels an acre are obtained; but in a rich soil well managed and in favourable years, 60, 70, and sometimes even 80 bushels and upwards have been reaped, weighing from 35 lbs. to 45 lbs. a bushel, and yielding 7 lbs. meal for 14 lbs. oats; but the proportion of meal increases as the oats become heavier. The price of oats amounted at an average of the 7 years ending with the 31st December, 1835, to 22*s*. per. Imp. quarter.

A′VENUE. (Lat. ad, *to*, and venio, *I come*.) In Landscape Gardening, is a road leading from some other road, and forming the main approach to a house; but it is also applied to any broad walk or road of grass or gravel, bordered on each side by lines of trees. When the modern style of gardening began to take the place of the ancient style, the term avenue gave way to that of approach road, which subsequently became shortened into that of approach.

A′VERAGE, GENERAL. In Mercantile Law, whatever damage or loss is incurred by any part of the ship or cargo for the preservation of the rest. When such damage accrues, the several persons interested in the ship, freight, and cargo, contribute their respective proportions to indemnify the owner of the part in question against the damage or necessary expense which has been incurred for the good of all. General average, therefore, cannot be unless the whole adventure has been in jeopardy. Every species of loss incurred on any part of the cargo in the course of the voyage, is somewhat loosely denominated average, or particular average. *See* Insurance.

AVE′RNUS. (Lat.) A lake of Italy 10 miles west of Naples, celebrated in antiquity as the entrance to the infernal regions. Strabo's description of this lake was well fitted to impress the minds of the "*profanum vulgus*" with superstitious awe. "Its steep and perilous banks were studded with mighty oaks that stretched their boughs over the watery abyss and excluded every ray of wholesome light; mephitic vapours ascending from the hot bowels of the earth floated along the surface of the lake in poisonous mist, while the dark and savage practices of the neighbouring people enhanced the horrors of the gloomy scene." A cave adjoining the lake is represented by Virgil as the habitation of the Cumæan sybil: —

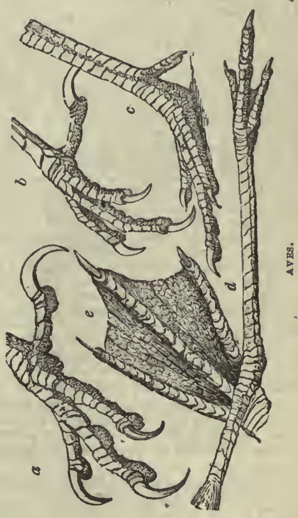
"Spelunca alta fuit, vastoque immanis hiatu,
Scrupea, tuta lacu nigro nemorumque tenebris;
Quam super haud ullæ poterant impune volantes
Tendere iter pennis: talis sese halitus atris
Faucibus effundens supera ad convexa ferebat; [out birds.
Unde locum Graii dixerunt nomine Avernum." (ἄορνος, with-

This place continued to be the favourite haunt of superstition till the time of Augustus, who violated its sanctity, and dispelled the impenetrable darkness in which it had hitherto been enshrouded, by cutting down the surrounding wood, and connecting it with the Lucrine lake, then an arm of the sea. This lake still exists under the name Lago d'Averno; it is about a mile and a half in circumference, and in many places 190 feet deep. Averni is a generic name for certain lakes or other places that infect the atmosphere with pestilential vapours, called also Mephites.

AVERRUNCA′TOR. (Lat. averrunco, *I dress* or *weed*.) In Arboriculture, is an instrument for cutting off the branches of trees, consisting of two blades fixed on the end of a rod; one of which has a moveable joint, which, by means of a line fixed to it, operates like a pair of scissors. In the improved forms of this instrument, the point on which the moving or cutting blade turns, instead of being confined to a circular opening, works in a longitudinal one; in consequence of which, instead of a crushing cut, like that produced by common hedge shears, a draw cut is formed, which leaves the section from which the branch or shoot has been amputated as clean as that produced by a pruning knife.

AVE′RSE. (Lat aversus, *turned back*.) In Ornithology, when the posterior extremities are attached to the trunk near the anus, so that the body is supported erect, as in the penguin, they are termed "pedes aversi."

A′VES. (Lat. avis, *a bird*.) The name of a class of warm-blooded vertebrated animals, characterised by a double circulation and respiration, oviparous generation, a covering of feathers, and by their anterior extremities being organised for flight. The posterior extremities present five principal modifications, affording characters which distinguish five primary orders. In the first order the foot (*a* fig.) has three toes before and one behind, all armed with long, strong, crooked, and more or less retractile talons, adapted to seize and lacerate a living prey; this structure is associated with a strong, curved, sharp-edged and sharp-pointed beak, often armed with a lateral tooth; a very muscular body, and capability of rapid and long-continued flight. The order is termed Raptores or Accipitres. The second type of foot presents three toes before and one behind, and placed on the same level; slender, flexible, of moderate length, and provided with long, pointed, and slightly curved claws. The two external toes are united by a very short membrane. A foot so constructed (*b* fig.) is especially adapted for the delicate operations of nest building, and for grasping and perching among the slender branches of trees; hence



AVES.

the order so characterised has been termed Insessores, and, from including the smaller tribes of birds, Passeres. In the third type of foot (*c* fig.) the hinder toe is raised above the level of the three anterior ones; this deteriorates the power of perching; but the other toes are strong, straight, and terminated by robust obtuse claws, adapted for scratching up the soil, and for running along the ground; the legs are for this purpose very strong and muscular, and the order so characterised is termed Rasores, or Gallinæ. The modification by which birds are enabled to wade and seek their food in water along the margins of rivers, lakes, and estuaries, is gained simply by elongating the bones of the leg (tibia and metatarsus), which are covered with a naked scaly skin. The three anterior toes are sometimes very long and slender, as in the Parra jacana, by which the bird can support itself upon the broad floating leaves of aquatic plants; sometimes they are of moderate length. The hind toe is elevated, short, and sometimes wanting (*d* fig.). The order of birds characterised by this form of leg and foot is termed Grallatores, from the resemblance of the pos-

terior extremities to stilts. In the last form of foot (*e* fig.) the toes are united by intervening webs; the legs are placed behind the centre of equilibrium; the body is protected by a dense covering of feathers, and a thick down next the skin; and the whole organisation is especially adapted for aquatic life. Hence the order is termed Natatores.

A'VIARY. (Lat. avis, *a bird.*) A place for keeping birds. In gardens, aviaries for singing birds are generally limited spaces attached to summer-houses or hot-houses, in which a temperature is kept up during winter suitable to the kind of bird or birds in the aviary. When an aviary contains only birds which live in climates analogous to that of Britain, it is formed in the open garden or pleasure ground, each kind of bird having a separate house; or, instead of a house, a small enclosure covered with netting to prevent it from flying away. The most common exotic singing birds kept in aviaries are canaries; and the most common exotic ornamental birds are turtle doves, and birds of the parrot tribe. The ornamental and curious birds which live in climates similar to that of Britain may be divided into two classes, the terrestrial and the aquatic. Of the former, the most ornamental are the gold and silver pheasants, and the common pigeon, including its numerous varieties; and among the latter, the white and black swans, the Muscovy duck, &c. The most complete aviaries in the neighbourhood of London, exclusive of those in the Zoological Gardens, are those at Woburn Abbey, and at Knowsley.

AVI'CULA. A name applied to a genus of bivalves, in some of the species of which the shell, when expanded, offers a slight resemblance to a bird flying. The shell is equivalve, with a rectilinear hinge, notched at the anterior edge for the passage of a hyssus: the anterior adductor muscle very small. To this genus belongs the celebrated pearl oyster, *Avicula margaritifera*.

AVOI'DANCE. In Ecclesiastical Law, signifies the condition of a benefice when void of an incumbent, and is opposed to plenarty.

A'VOIRDUPO'IS, or AVERDUPOIS. (Fr. avoir du pois, *to have weight;* or perhaps from an old French verb, averer, *to verify.*) The name given to the common system of weights in England, by which goods in general, excepting the precious stones and medicines, are weighed. The standard weight of this country is the grain, which is ordered by act of parliament, 5 Geo. IV. c. 74., to be such that "a cubic inch of distilled water, weighed in air by brass weights, at the temperature of 62 degrees of Fahrenheit's thermometer, the barometer being at 30 inches, is equal to two hundred and fifty-two grains, and four hundred and fifty-eight thousandth parts of a grain. A pound avoirdupois contains 7000 grains. The pound is subdivided into 16 ounces, and the ounce into 16 drams. The higher denominations are the quarter-hundred, the hundredweight, and the ton; 28 pounds making a quarter, 112 pounds a hundredweight, and 20 hundredweights a ton. The pound avoirdupois is greater than the pound troy; the latter containing only 5760 grains. But the troy ounce, which contains the twelfth part of 5760, or 480 grains, is greater than the ounce avoirdupois, which contains the sixteenth part of 7000, or 437½ grains. The avoirdupois ounce is considered as being the Roman uncia, which, according to Dr. Arbuthnot, contains $437\frac{1}{7}$ grains, though other authorities make it several grains less. The term averdupois occurs in some orders of Henry VIII., A.D. 1532; and Queen Elizabeth, in 1588, ordered a pound of this weight to be deposited in the Exchequer as a standard. *See* WEIGHTS.

AVOSE'T. A native wading bird, characterised by a long recurved bill. *See* RECURVIROSTRA.

AVOW'RY. In Law, the justification advanced in pleading by one who has taken a distress in his own right when sued in replevin. The avowry must contain a sufficient averment of right to have return. One who justifies as having taken in the right of another, is said to make cognizance. *See* REPLEVIN.

AWA'RD. In Law, the judgment pronounced by one or more arbitrators, at the request of two parties who are at variance, for ending the matter in dispute without the decision of a public tribunal. The act of reference to an arbitrator is termed a submission.

By the stat. 9 & 10 W. 3. c. 15. it is provided that parties desirous to end a controversy may agree that their submission of the suit to arbitration shall be made a rule of any court of record; and, after such rule the party disobeying the award is liable to be punished for a contempt of the court. But the award may be set aside for various causes, as corruption, informality, &c., by motion in court within one term after the award is made. When submission to arbitration has been made a rule of court, it is, by 3 & 4 W. 4. c. 42. s. 39., not revocable by either party without leave of the court. The arbitrators have a jurisdiction over the costs of the action as well as over the matter in controversy; and, in case of a reference at nisi prius, they may refer the costs to be taxed by the proper officer of the court. An award must be made in writing, signed and sealed by the arbitrators.

AWN. (Derivation unknown.) A stiff, usually rough, bristle, proceeding from the end or some other part of a leaf, or of a leafy organ; it is the beard of grasses, and often proceeds in those plants from the base of either glumes or paleæ. An awn is in reality either a vein separating from its parenchyma, or a rigid sharp-pointed barren branch of inflorescence. A part is said to be awned, or aristate, when furnished with this organ.

AW'NING. In Hort., a temporary covering for plants, generally consisting of cloth of some kind, stretched by means of ropes, cords, or wooden rods, so as to protect fruit trees against a wall, or flowers in a bed. An awning for a tulip bed is the most complete structure of this description, and is so constructed, by means of lines and pullies, that the sheeting can be either pulled up or let down over a bed of considerable length in two or three minutes.

A'XESTONE. A tough silico-magnesian stone, sometimes shaped into cutting instruments. *See* NEPHRITE.

AXI'FEROUS. (Lat. axis, *a centre*, and fero, *I bear.*) A name given to those plants which, like lichens, fungi, &c., consist exclusively of an axis, without any leaves or appendages of it.

A'XIL. (Lat. axilla, *the armpit.*) That part of a plant where a leaf fits on a branch, forming an angle with it: or where two branches diverge from each other.

A'XILE. (Axis.) Lying in the axis of any thing; as an embryo, which lies in the axis of a seed, that is from the base to the end diametrically opposite.

AXI'LLA. (Lat. axilla, *the armpit.*) In Anatomy, the hollow below the base of the arm, at its insertion into the chest. An interesting region in topographical anatomy, containing important arteries, veins, nerves, glands, &c. which are termed 'axillary.'

AXI'LLARY. Growing in an axil. The term is modified by the prefixing different Latin prepositions: thus, infra axillary, signifies growing from below the axil; extra axillary, on one side of it; and supra axillary, from above it.

A'XINITE. (Gr. ἀξίνη, *an axe.*) A mineral usually occurring in axeshaped crystals; it is an alumino-silicate of lime and iron.

A'XIOM. (Gr. ἀξιόω, *I demand.*) In Geometry, a proposition which it is necessary to take for granted, and which therefore admits of no demonstration. The following are among the propositions of this kind enunciated by Euclid: "Things that are equal to the same thing are equal to one another." "The whole is greater than its part." "If equals be added to equals, the sums will be equal." "If two figures when placed the one on the other entirely coincide, they are equal in every respect." The formal statement of such propositions is totally useless, or rather tends only to produce obscurity.

AXIOM. In Philosophy, properly that which is demanded, or postulate. It is used, in the mathematical and physical sciences, in the sense of a proposition, to which the assent of the student is demanded without proof, as a foundation for farther argument.

A'XIS. (Lat. *an axletree.*) That part in plants about which particular organs are arranged. Thus, the stem is an axis for the branches; a branch, an axis for leaves; the rachis, an axis for the divisions of inflorescence; and the receptacle, gynobase, or columella, is the axis of the fruit. The term is also applied to the imaginary point round which parts of any sort are arranged.

AXIS. (Lat. axis.) In Architecture, a real or imaginary straight line passing through any body on which it may revolve; the axis of a column, for instance, is a straight line drawn down through its centre; the axis of the Ionic volute is a line drawn through the two eyes, front and rear.

AXIS. (Lat. axis.) In Mechanics, signifies in general the straight line, real or imaginary, about which a body turns. In this sense it is called the axis of rotation, of oscillation, &c., according to the motion of the body. In Geometry, the axis of a figure is a straight line about which the parts of the figure are symmetrically disposed. Thus, the axis of a cone is the line drawn from the vertex to the centre of the base; and the axis of a cylinder, the line drawn through the centre of its two ends. In the ellipse and hyperbola, the transverse axis is the straight line drawn through the two foci; and the conjugate axis, that drawn through the centre, perpendicular to the transverse. In general, by the axis of a curve line is meant that diameter which has its ordinates at right angles to it. We also speak of the axes of the co-ordinates of a curve, meaning the line on which the abscissa are taken.

AXIS IN PERITROCHIO. One of the five mechanical powers, consisting of a peritrochium or wheel fixed immovably to an axle, so that both turn together round the axis of motion. The power is applied at the cir-

cumference of the wheel, and the weight raised by a rope wound round the axle. The power gained is the same as that gained by a lever, the longer arm of which is equal to the radius of the wheel, and the shorter equal to the radius of the axle; so that if we suppose the radius of the wheel to be 30 inches, and the radius of the axle 6 inches, a weight of one pound suspended by a rope passing round the wheel would raise a weight of five pounds similarly suspended from the axle.

A'XOLOTL. (Axolotes, is, em, ibus.) A term derived from the Mexican language, and applied to a genus of Perennibranchiate Amphibians, found in the lake of Mexico.

AYE-AYE. The name of a singular nocturnal quadruped of Madagascar, indicative of its peculiar cry; it is placed by Cuvier in the Rodent order, under the generic name Cheiromys, from the hand-like structure of the hinder feet; a structure which approximates the genus to the monkey tribe, or Quadrumana, in which other naturalists have placed it.

AZA'LEA. (Gr. ἀζαλεος, *dry.*) A genus of beautiful plants inhabiting North America and China. They have trumpet-shaped or bell-shaped richly coloured flowers, which are in some species fragrant. The name has apparently been derived from the dry brittle nature of their branches. They differ from rhododendron chiefly in being deciduous.

A'ZIMUTH. (From the Arabic.) A term used in astronomy, to denote the arc of the horizon intercepted between the meridian and the vertical circle passing through a star or other celestial body; or the angle made at the zenith by the meridian and the vertical circle in which the body is situated. The azimuth may be counted either from the north or the south point of the horizon: modern astronomers seem to prefer beginning at the north point, and counting eastward and westward to 180°; but it is not one of those elements usually observed in astronomy, being easily deduced from the declination, which can be measured much more conveniently and accurately. In trigonometrical surveys, however, on the earth's surface, the accurate determination of the azimuth of an object is an operation of very great importance. It is usually made with the theodolite.

AZIMUTH CIRCLES, or VERTICAL CIRCLES, are great circles of the sphere passing through the zenith, and intersecting the horizon at right angles.

AZIMUTH COMPASS. A compass used at sea for finding the horizontal distance of the sun or a star from the magnetic meridian.

AZIMUTH DIAL. A dial of which the stile or gnomon is perpendicular to the plane of the horizon. It is so called because the shadow marks the sun's azimuth.

A'ZOTANE. Sir H. Davy proposed to designate the compounds of chlorine by the termination *ane*, and consequently distinguished the compound of chlorine and azote, or chloride of azote, by the above name.

A'ZOTE. (Gr. ἀ, *not*, and ζωη, *life*.) A simple gaseous body, unfit for respiration; it forms four-fifths of our atmosphere. *See* NITROGEN.

A'ZURE. (Fr. azur.) In Painting, a sky-coloured blue. That made of lapis lazuli, called ultramarine, is of great value to the painter.

A'ZURE. (Fr. azur, *blue*.) In Heraldry, one of the colours, or tinctures, employed in blazonry. It is equivalent to sapphire among precious stones, and Jupiter among planets. In engraving it is represented by horizontal lines.

A'ZURITE. *See* LAZULITE.

A'ZYGOS. (Gr. ἀ, *without*, and ζυγον, *a yoke*, because it has no fellow.) In Anatomy, some single muscles, bones, veins, &c., are so called.

B.

B. The second letter in all European alphabets, and in that of most other languages. B is one of those letters which the Eastern grammarians call labial, because the principal organs employed in its pronunciation are the lips. It has a close affinity to the other labial letters P and V; and by the Saxons it is confounded with the former, and with the latter by the modern Greeks, Spaniards, and Gascons. Hence the sarcastic remark, that in Gascony "vivere" and "bibere" are the same thing. Among the Greeks and Hebrews, B signified 2; among the Romans 300 (et B tricentum per se retinere videtur); with a dash over it it denoted 3000, and with a kind of accent below it 200. The Romans also used it in inscriptions as an abbreviation for Baccho, Beleno, Benemerenti, &c.; B. B. for bene bene (i.e. Optime), B. L. for lector benevole, B. F. (affixed to decrees or senatus consulta) for bonum factum. In modern times also it is used as an abbreviation for *before*, as B.C. (before Christ); and for *bachelor*, as, B.A., B.LL., B.D. (bachelor of arts, of laws, of divinity). In music, B is the note on the second line in the bass, and the third in the treble; and in the chemical alphabet, according to Raymond Lully, it denotes mercury.

B MOLLE. (Lat. molle, *soft*.) In Music, one of the notes in the musical scale, usually called soft or flat ♭, to distinguish it from B quadro (square), ♮.

BAAL, or BEL. (Heb.) A god of the Phœnicians and Carthaginians, worshipped chiefly at Tyre. The term Baal, common to all the Eastern languages, signifies lord or master; and this circumstance has probably given rise to the various contradictory opinions that prevail respecting this divinity. Servius (in Am. I.), who is followed by Vossius (*Theol. Gent.* b. xi. c. 4.), observes that Baal in the Runic language had two significations: the one denoting Saturn, the other equivalent to the Greek Ζευς. Accordingly, if Baal and Ζευς be words of similar import in different languages, we may apply to the former what Varro relates of the latter, that the number of divinities worshipped under this title amounted to three hundred. This opinion, it would appear, was held also by Milton,

> With these came they who, from the bordering flood
> Of old Euphrates, to the brook that parts
> Egypt from Syrian ground, had general names
> Of *Baalim* and Astaroth, &c. &c.

It is probable that the Baal of the Phœnicians, and the Belus of the Babylonians, whose worship was so assiduously cultivated (*Herod.* i.), were one and the same divinity. The priests of Baal amounted to 450; and, among other sacrifices offered upon his shrine, the Bible mentions human victims. To the zealous devotion paid by the Eastern nations to this divinity, and the wide circulation of his worship, the adoption of his name in the appellation of distinguished individuals, such as Hannibal, Belshazar, Asdrubal, &c., bears ample testimony. (Selden, *de Diis Syris*; *Shuckford's Connection*, b. v.)

BA'BEL. (Heb.) A tower undertaken to be built shortly after the flood by the posterity of Noah, and remarkable for the frustration of the attempt by the confusion of languages. About 1700 years after the erection of the tower of Babel, Herodotus saw at Babylon a structure consisting of eight towers, raised one above another, and each 75 feet high (*Herod.* b. i.); but whether this structure was the famed tower of Babel or not, it is impossible to ascertain. It is generally supposed, however, both by ancient and modern writers, that the city of Babylon afterwards occupied the site of Babel, and that the famous temple of Belus was built from its ruins. A great difference of tradition prevails as to the height of the tower of Babel. While the orientalists maintain that it was 10,000 fathoms, or about 12 miles high, St. Jerome asserts, on the authority of eyewitnesses who had examined the ruins of a tower at Babylon, that it was 4 miles high, and there are other statements still more extravagant. With regard to modern travellers who pretend to identify the ruins found on or near the site of ancient Babylon with the tower of Babel, their accounts are so discrepant and indefinite, as to render it doubtful if any of them have seen the genuine ruins of this celebrated tower. (*Rich's Travels; Buckingham's Travels in Mesopotamia; Rennel's Remarks on Herodotus.*)

BABIA'NA. A genus of Cape plants belonging to the natural order *Iridaceæ*. The name is derived from *Babianer*, a term given by the Dutch colonists to these plants in consequence of the avidity with which their roots are devoured by the baboons.

BA'BILLARD. The name of a small frugivorous Passerine bird, the *Curruca gurrula:* also called the white-breasted or babbling fauvette, lesser white throat, and nettle-creeper.

BABOO'N. The monkeys, or quadrumana, which have projecting ridges above the eyes, long and truncate muzzles, cheek-pouches, ischiatic callosities, and generally short tails.

BABYROU'SSA. The name of an animal of the hog kind (*Sus babirussa* Cuv.) inhabiting the forests of the Indian Archipelago, with longer legs and longer tusks than the other species of hog; both the upper and the lower tusks curve upwards and backwards, and serve as a defence to the eyes while the animal forces its passage through the entangled jungles.

BA'CCA. A berry; usually a succulent fruit containing several seeds. In its most exact application it is a succulent fruit filled with pulp, in which the seeds lie loosely, as in the gooseberry.

BACCALAU'REAT. (Lat.) The first or lowest academical degree in the English and French universities. The mode by which this degree is attainable is different in different universities. Oxford and Cambridge have two ways of conferring it: 1. By examination, to which those students alone are admissible who have pursued the prescribed course of study for the space of three years. 2. By extraordinary diploma, granted to individuals wholly unconnected with the university. The former class are styled Baccalaurei Formati, the latter Baccalaurei Currentes. In France, the degree of

Baccalaureat (Baccalaureus Literarum) is conferred indiscriminately upon such natives or foreigners as, after a strict examination in the classics, mathematics, and philosophy, are declared to be qualified. In the German universities, the title "Doctor Philosophiæ," has long been substituted for Baccalaureus Artium or Literarum. In the middle ages, the term Baccalaureus was applied to an inferior order of knights, who came into the field unattended by vassals: from them it was transferred to the lowest class of ecclesiastics; and thence again, by Pope Gregory IX., to the universities. There are few words whose origin has been more controverted than that of Baccalaureat; and both the military and literary classes have asserted their claims to this honour with equal zeal and ingenuity. While the former maintain that it is either derived from the *baculus* or staff with which knights were usually invested, or from *bas chevalier* (an inferior kind of knight), the latter, perhaps with more plausibility, trace its origin to the custom which prevailed universally among the Greeks and Romans, and which was followed even in Italy till the thirteenth century, of crowning distinguished individuals with laurel: hence the recipient of this honour was styled Baccalaureus (quasi *baccis laureis* donatus).

BACCAULA'RIS. A fruit consisting of several distinct carpels, having a succulent coating, and seated upon a short receptacle.

BA'CCHA. In Entomology, a genus of the order *Diptera*, and family *Syrphidæ*. The two basal joints of the abdomen are long and slender, with the remaining joints depressed and broad; they are bronze colour marked with yellow, and are found upon flowers in the neighbourhood of London.

BACCHANA'LIA. (Lat.) Festivals in honour of Bacchus. In the mythology of the Greeks and Romans, allusion is constantly made to the conquest which Bacchus achieved over India, and it is generally supposed that these festivals were instituted to commemorate that event. They consisted originally of a grand procession, in which the priests and priestesses of Bacchus bore the principal part, and were accompanied with games, spectacles, and theatrical representations. But, at a later period of Grecian history, they assumed a totally different character: vice, debauchery, and licentiousness became their distinguishing characteristics; and Plato (*de Leg.* l. i.) asserts that during the celebration of these festivals he has seen the whole Athenian populace in a state of drunkenness. At Athens, there were two principal Bacchanalia held annually: viz. Bacchanalia Dionysia or Majora, celebrated in the city about spring time; and Bacchanalia Lenæa or Minora (so called from ληνος, a wine press), celebrated in the country during autumn. On these occasions, the Bacchæ or priestesses of the god ran up and down the mountains in a frantic manner (*Stat. Theb.* vi. 92.), clad in doe-skins, with spears in their hands, bound at the points with ivy-leaves (thyrsi), and using the wildest gestures and exclamations. (See the *Bacchæ of Euripides*.)

These festivals were introduced from Greece into Etruria, and thence by an easy transfer into Rome, where they were at first celebrated chiefly by young men on their laying aside the toga prætexta for the toga virilis. But they soon after extended among all classes of the community; and in the course of time such were the enormities practised at their celebration, that the senate (A. U. C. 566) came to the resolution of abolishing them entirely. Virgil, in the 7th book of the *Æneid*, gives a graphic description of these festivals, and says that the priestesses

> —— tremulis ululatibus æthera complent,
> Pampineasque gerunt, incinctæ pellibus, hastas.

And Juvenal uses the term Bacchanalia to express a dissolute and licentious life:

> Qui Curios simulant, et Bacchanalia vivunt.

BA'CCHUS, or DIONY'SUS (Διόνυσος). The god of wine, and son of Jupiter and Semele daughter of Cadmus. His mother perished in the burning embraces of the god, whom she persuaded to visit her with his attribute of royalty, the thunderbolt; the embryo child was sewn up in Jupiter's thigh, whence in due time he was produced to light. Mythology abounds with the adventures of Bacchus, the most noted of which are, the transformation of the Tyrrhenian pirates, who carried him off to sell for a slave, into dolphins; his revenge on the scoffing Pentheus; and his invasion and conquest of India. Bacchus was generally represented as a young man of effeminate appearance, with a garland of ivy binding his long hair; in his hand he bore a thyrsus or rod wreathed with ivy, and at his feet lay his attendant panther.

BACCI'FEROUS. Bearing berries.

BA'CHELOR. In the English Universities, the lowest degree in arts, law, divinity, medicine, and music. It is, like other university honours, of French origin. For the various derivations that have been suggested for this word, *see* BACCALAUREAT.

BACHELOR. In Heraldry, the lowest order of knighthood. *See* KNIGHT.

BACHELOR. In the Livery Companies of London, is one who is not yet admitted of the livery; also called *yeoman*.

BACILLA'REÆ. A small group of Algaceous plants, having an extremely simple structure, and in part the same as what are called Cymbelleæ. They stand on the limits of the animal and vegetable kingdoms, and are said to have a power of spontaneous motion.

BACI'LLUS. A name given to the cotyledon of the hyacinth by Link.

BACK (from the Saxon bæc) OF A HIP. In Architecture, the upper faces of the hip-rafter between the two sides of a hipped roof, so formed to an angle as to be in the same plane with the rafters on each side of it.

BA'CKER. In Architecture, a term used to denote a narrow slate laid on the back of a broad square-headed slate where the slates begin to diminish in width.

BACKGA'MMON. A game played with dice by two persons on a table divided into two parts, upon which there are 12 black and as many white spaces, called *points*. Each player has 15 men, black and white, to distinguish them. This game is of Welch origin, and is said to have been invented in the period preceding the Conquest. (*Gloss. ad Leges Wallic.*, cited by Henry, vol. iv. p. 404.) Backgammon can only be learned by observation and practice; and though much depends on chance, still great skill may be displayed in the course of the game. Hoyle, the received oracle in these matters, has evinced great accuracy in calculating the odds of backgammon, and has embodied a variety of rules and instructions respecting it, which must prove of great service to every player.

BACK THE OARS. To row the oars backwards.

BACK AND FILL. To keep a ship in the middle of the stream of a narrow river, by alternately advancing ahead from one shore and moving backwards from the opposite shore, while the stream carries her along, the wind being contrary to the direction of the stream.

BACK-STAFF. An instrument used before the invention of the quadrant and sextant, for taking the sun's altitude at sea. In using it the observer turned his back to the sun, whence the instrument had its name. It was invented by Captain John Davis, about the year 1590.

BACK-STAYS. In Sea language, ropes stretched from the top-mast heads to the starboard and larboard sides of the ship, their use being to support the top-masts, and second the efforts of the shrouds. They are distinguished into *breast back-stays* and *after back-stays*, according as the strain on the mast is caused by a side-wind, or a wind further aft. *See* RIGGING.

BACO'NIAN PHILOSOPHY. The system propounded by Francis Bacon, Lord Verulam. It is usual to speak of this philosophy as if it were a new invention of its illustrious founder—as if the method of induction were a mode of philosophising unknown before his time, and in direct opposition to preceding systems, especially that of Aristotle: this opinion, we conceive, is entirely erroneous. Aristotle has in many parts of his works clearly and satisfactorily explained the inductive method, and has himself, in his physical writings, given examples of its application. Lord Bacon's distinguishing merit consists, we believe, rather in the attention which, by his splendid eloquence, his wonderful power of illustration, his comprehensive views of the relations of the sciences to each other, and his unhesitating faith in the boundless progressiveness of human knowledge, he succeeded in awakening in the minds of his countrymen, than in any philosophical discoveries properly so called. No man, we admit, ever obtained a clearer insight into the nature and province of inductive research; no man, certainly, has laid down with such rigour and accuracy the rules for its successful prosecution. The various modes of experimenting and observing (in the language of Bacon *instances*) are classed under twenty-seven heads; and the circumstances under which each kind is applicable are stated with great fulness and accuracy. This is done in the second book of his *Novum Organon;* the former book of which consists of aphorisms on the errors of the human intellect generally, and in particular of preceding philosophical systems. These delusions, under the name of idols, he reduces to four classes: the *idols of the tribe*, or those common to human nature generally; the *idols of the cave*, or those generated by individual peculiarities; the *idols of the market-place*, produced by the incorrect use of words in ordinary discourse; and lastly, the superstitions introduced by false and visionary systems of philosophy, to which the name is assigned of the *idols of the theatre*. His own method he designates as holding an intermediate place between the merely empirical and the dogmatical schools. "While the one," says he, "like ants, content themselves with heaping up materials for immediate use, the latter, after the manner of spiders, spin webs out of their own

train: there is a middle and a better way — that of the bee, which derives, indeed, its material from the flowers of the garden and the field, but converts and digests it by its own proper virtue." These two books of the Organon form the second great division of his projected undertaking, the *Instauratio Magna*, or *Reform of Philosophy*, and relate to the interpretation of nature. The treatise *De Augmentis Scientiarum* (*of the Advancement of Learning*) constitutes the first division: the third was to consist of a history of the phenomena of the universe: the fourth (*Scala Intellectus*) was to comprise an account of the processes of the human understanding, with examples from various sciences: in the fifth was to be contained the introduction to the *Philosophia Secunda*, or *Active Philosophy*, which, as the combined result of history and experience, was itself to constitute the sixth and last division. (See his *Distributio Operis; Bacon's Works*, 4to ed. vol. iv.) Of this mighty work Bacon only completed the first two divisions. For a comprehensive and impartial estimate of the value of the Baconian philosophy, the German scholar may consult Tennemann's *Geschichte der Philosophie*, 10ter band. (Leipzig, 1817.) An account of the *Novum Organon* has been published by the Society for the Diffusion of Useful Knowledge.

BA'CTRIS. (Gr. βακτρον, *a cane*.) A genus of palms with spiny slender stems and pinnated leaves. Their fruit is succulent, and manufactured into a kind of wine; walking sticks are made from their stems.

BA'CULITES. (Lat. baculum, *a stick*.) A genus of fossil Tetrabranchiate Cephalopods, the chambered shells of which are quite straight, but differ from those of the Orthoceratites in having sinuous or undulated partitions with lobated margins: in this structure they are allied to the Ammonites.

BA'DGER. *See* MELES.

BA'DISTER. In Entomology, a genus of the order *Coleoptera*, and family *Harpalidæ*. This genus, with some others, forms a leading group among the carnivorous beetles.

BA'GGAGE. (Fr. bagage.) In the art Military, the clothes, tents, provisions, and other necessaries belonging to an army. In regard to the conveyance of baggage, a striking contrast is presented between the military systems of ancient and modern times. The Roman soldiers had four kinds of baggage (bucellatum or corn, utensils of various kinds, valli, and arms), termed by a felicity of language *impedimenta*; and were so heavily laden, that they were called by way of jest *muli Mariani*, and *ærumnæ*. In modern times, the plan is every where adopted of ridding the soldier of all unnecessary encumbrance; and with this view waggons attached to each battalion are employed for the conveyance of baggage, and guarded and regulated by a body of men set apart for the purpose, called the waggon-train.

BA'GGING. A mode of reaping corn or pulse with a hook, in which the operator effects his object by striking the straw or haulm, instead of drawing the hook through it. In other words, it is separating the straw or haulm from the root by chopping, instead of by a drawing cut.

BA'GPIPE. This instrument appears to be of ancient origin, and is very similar to the *tibia utricularis* described by Blanchinus. A representation of it is given by Luscinius in his *Musurgia* (1536), whence it appears that at that time the instrument was similar to that now in use. It consists of a leather bag, inflated through a valved tube by the mouth (or a bellows), and of three pipes; two of which give only one note each, and are called the great and little drone; and the third, somewhat like the oboe, has eight finger holes. The bagpipe is peculiar to the Scotch and Irish nations.

BA'IKALITE. A manganesian epidote from lake Baikal in Siberia.

BAIL (Old Fr. bailler, *to deliver or give up*), in Law, is the liberation of one in custody, whether for a civil or criminal cause, on surety taken for his appearance at a day and place certain. In civil cases bail is chiefly of two kinds, called bail to the sheriff, and bail to the action; or, in other terms, bail above and bail below. When a person is arrested upon an affidavit made that he is indebted to the plaintiff in the sum of 20*l*. or upwards (which, since the recent act for abolishing arrest on mesne process, 1 & 2 Vict. c. 10., must also state that there is probable cause for believing that the defendant is about to quit England), he has then, in order to regain his liberty (unless previously discharged under a judge's order), to execute a bail bond to the sheriff, the condition of which is, that he will at the proper period put in special bail, which amounts to an appearance in court: at this period he either puts in special bail, who are two or more persons, who undertake generally that if the defendant lose the verdict he shall pay the amount awarded against him, or render himself to custody, or that they will do it for him. In default of special bail he returns again into custody.

Bail, in cases of felony, is taken by two magistrates in cases where the evidence against the prisoner is not such as to raise a strong presumption of his guilt.

BAIL-BOND, in Law, is a deed executed by a party arrested on mesne process (*see* ARREST), and two persons as his sureties, to the sheriff, conditioned for his causing special bail to be put in. If the defendant neglect afterwards to put in and perfect such bail, the plaintiff usually takes from the sheriff an assignment of the bail-bond, and proceeds against the defendant in a separate action.

BAI'LIE. The name by which the municipal magistrates of Scotland are designated. The term is synonymous with *alderman*.

BAI'LIFF. (Fr. bailler, *to deliver*.) The term properly meant "lessee:" whence it came to signify more generally deputy, and was applied to those officers who, by virtue of deputation either from the sheriff or the lords of private jurisdictions, exercised within the hundred, or whatever might be the limits of their bailiwick, certain judicial and ministerial functions. With the disuse of private and local jurisdictions, the meaning of the term became commonly restricted to such persons as were deputed by the sheriff to assist him in the merely ministerial portion of his duty, such as the summoning of juries and the execution of writs. These persons are called bound bailiffs, so termed from the obligation which they enter into to indemnify the sheriff against the consequences of his responsibility for their right conduct in the discharge of their duty.

BAI'LIWICK. (Fr. bailli, *bailiff*, and Lat. vicus, *a village*.) The dwelling-place or district of the bailiff: it also signifies a county, which is the bailiwick of the sheriff, or the particular franchise of some lord who has exclusive authority within its limits.

BAI'LMENT. In Law, is a delivery of goods in trust, upon a contract, express or implied, that the trust shall be faithfully executed on the part of the bailee, or receiver. Transactions with carriers, agents, pawnbrokers, and many other mercantile proceedings, are affected by the law of bailment.

BA'IRAM. A Mohammedan feast, instituted in imitation of the Easter of the Christian church, and following the Rhamaan, or month of fasting, which answers to our Lent. In consequence of the Turkish mode of reckoning by lunar months, these periods fall successively in all the seasons during a cycle of thirty-three years. Sixty days after the greater follows a second feast, termed the lesser Bairam.

BA'JADERES. The name given by the Portuguese to the Indian dancing girls, who, under various appellations, are partly employed as priestesses, and instructed in music and dancing by the priests of Schiva and Vishnu, partly employed by the grandees of India to cheer their festivities and minister to their pleasure. Their dress consists of costly materials, tastefully arranged; and their movements are most dexterous, graceful, and fascinating, at least if we may judge of them from the Bajaderes that appeared at the *Adelphi* theatre in the autumn of 1838. In their whole character and proceedings, they bear a strong resemblance to the *Hierodouloi* of the Greeks.

BA'JULUS. (Lat. *porter*.) In the Lower Greek Empire, the title of the officer to whom the education of a prince was entrusted. The name was borrowed by various Western courts which imitated the etiquette of Constantinople, and from it some have erroneously derived that of bailiff.

BALÆ'NA. (Gr. φαλαινα.) The Greenland whale; also a generic term, comprehending the species which agree with it in the presence of whalebone in the mouth and the absence of a dorsal fin.

It is to this genus that the whale, properly so called, or large-walebone whale (*Balæna mysticetus*, Linn.), belongs, the value of which to man is such that large fleets are annually fitted out expressly for its capture. The food of the whale consists exclusively of small molluscous and crustaceous animals, but chiefly the *Clio borealis*; and as these animals abound only in the Arctic seas, the whale cannot be expected to frequent for any length of time those latitudes in which its food is scarce or altogether wanting. The long-continued annual destruction of the *Balæna mysticetus* has greatly diminished the numbers of this species, and driven those which remain to the extremest limits of the northern seas where their means of subsistence can be obtained.

The large-whalebone whale is often spoken of as the largest of existing animals, but it is inferior in magnitude to the small-whalebone whale (*Balænoptera*). The latter attains the length of from 90 to 100 feet; while the ordinary dimensions of the true whale are from 50 to 60 feet in length, and from 30 to 40 feet in circumference. The terms "large-whalebone" and "small-whalebone" relate to the size of the whalebone or baleen-plates, which is always much greater in the genus *Balæna* than in *Balænoptera*; and it is this structure, combined with the greater amount of blubber in the true whale, which renders it an object of so much more value to the whale catchers; while its less courageous habits, and less violent

efforts to escape when wounded, make it a more sure and safe prey than the small-whalebone whale.

The true whale is chiefly remarkable for the immense size of its head, white constitutes a full third of the entire length of the animal: it is narrow above, but very broad below, where it consists chiefly of a large under lip, which rises five or six feet, and completely overlaps the upper lip. The eyes are very small, and are placed just above the angles of the mouth. The external opening of the ears is scarcely perceptible. The pectoral fins are of moderate size, and placed about two feet behind the angles of the mouth. The neck is indicated by some furrowing of the skin, but there is no constriction. The greatest circumference of the cylindrical body is a little behind the pectoral fins. The tail-fin consists of two lobes of great breadth, measuring 20 feet across from tip to tip in a full-grown specimen; and wielded by muscles of enormous power. It is this part which constitutes the sole organ of offence and defence in the whale, for it has no teeth wherewith to bite or lacerate; a single blow of the tail well delivered suffices to cut a stout boat in two, or to send it whirling through the air.

The plates of whalebone are the substitutes for teeth in the mouth; they have a similar mode of development from a pulp and external membrane, and differ only in form, and in a less proportion of earthy matter in their composition. They are arranged vertically and transversely, in two series, consisting each of 300 plates, descending from the palatal surface of the upper jaw, and terminating in a fringe of coarse hairs on their oblique lower and inner margins, which hairs are in contact with the upper surface of the bulky tongue when the mouth is closed. It is thus that the mechanism of the sieve is realised on an enormous scale; and while the water gulped at each successive mouthful is drained off through the interstices of the baleen plates, the molluscous and crustaceous animals are retained, bruised into a pulp between the muscular tongue and coarse fibres of the whalebone, and swallowed. The area of the gullet corresponds with the minute character of the food, and is relatively smaller in the whale than in any other animal. The stomach is divided into four cavities; the intestinal canal is long and narrow, and provided with a short and simple cœcum.

The whale has usually but one young at a birth, and brings forth in the early spring. The period of gestation is unknown, that of suckling lasts a year. In this stage of their growth the young are called *short heads* by the whale-fishers; at two years old, and until they are able to find their appropriate food in due abundance, they are termed *stunts;* when they begin to get fat, and until they have arrived at their full size, they are called *skull-fish*.

The interesting details of the profitable but perilous occupation of whale-fishing, will be found most amply and correctly given in *Scoresby's Account of the Arctic Regions*, from which many popular narratives have been compiled. The baleen and the blubber are the only parts of the animal of any commercial value, and the quantity of both yielded by these enormous animals is of course considerable. The length of the largest whalebone plates in a whale of 60 feet is as much as 12 feet; and the blubber of such a one will yield more than 20 tuns of pure oil, the proportion of oil to the blubber from which it is extracted being as three to four. The blubber is principally accumulated at the circumference of the body, beneath, and in the extended tissue of the skin; an immense quantity of fine oil is also lodged in the cellular substance of the tongue; and the coarse and porous bones, particularly the lower jaw, are full of pure oil.

BA'LANCE. (Lat. balanx or bilanx, probably a corruption of valentia, denoting, in low Latin, *price* or *value.*) A machine for weighing substances. The process of weighing may be performed in various ways, and accordingly there are several kinds of balances; as the common balance or scales, the bent lever balance, the spring balance, the steel-yard, the hydrostatic balance, &c. (for which see the respective words). The term is also applied to any apparatus employed for comparing the intensities of very small forces, as the electric balance, the balance of torsion, &c. We shall here confine our remarks to the philosophical balance, the instrument used when great accuracy is necessary; for instance in assaying, and in the more delicate investigations of physics and chemistry.

Neglecting the mere circumstance of construction, and the particular methods of suspension, the balance may be represented thus:—

A and B are the points from which the scales are suspended at the extremities of the beam, C the point of support, G the centre of gravity of the beam, D the point in which the straight line C G intersects the straight line joining A and B.

The properties required in a good balance are *sensibility* and *stability*. The balance must be sensible; that is to say, when it is properly poised a very small addition of weight to either scale should disturb the equilibrium, and cause the beam to turn; and it must be stable, that is to say, when the equilibrium has been disturbed it should quickly return, and oscillate about the position of rest. These two properties are in some degree opposed to each other; in order to attain them both, as far as possible, it is necessary to attend to certain mechanical principles, as well as to the physical circumstances of construction. Let us suppose

W = the weight of the beam.

L = the load, *i. e.* the weight of the scales and whatever is in them when the beam is poised.

P = the preponderating weight, or that which causes the beam to turn.

Suppose now the beam to be poised, or that the scales being loaded the position of the line A B is perfectly horizontal. The sensibility will evidently be measured by the angular space through which the beam turns when a small weight P is added to either scale; but the force which acts in turning the beam is proportional to $P \times DB$, that is, proportional to the weight multiplied into the length of the lever at the extremity of which it acts; therefore for a given weight P, the sensibility of the balance, all other circumstances being equal, is proportional to the length of the beam. Let us next consider the force which tends to restore the beam when the equilibrium is disturbed. This is made up of two parts; the first of which is proportional to $W \times CG$, that is to say, proportional to the weight of the beam (which may be regarded as concentrated at the centre of gravity) multiplied into the length of the lever on which it acts; and the second proportional to $L \times CD$, that is, to the load also multiplied into its length of lever. The whole restoring force is therefore proportional to $W \times CG + L \times CD$. Now this force is precisely that which the preponderating weight P has to overcome in turning the scale; consequently any circumstance which tends to increase it, increases the stability and diminishes the sensibility of the balance; and anything which tends to diminish it, diminishes the stability and increases the sensibility. By bending the arms of the balance, or altering the points of suspension of the scales, the points G and D may acquire different positions relatively to C. Supposing G to be above C in the vertical line joining those points; the term $W \times CG$ would become negative, and the restoring force proportional to $L \times CD - W \times CG$. In this case, if the load L, or the distance C D, were diminished till $L \times CD$ became less than $W \times CG$, the balance would be useless; because if moved ever so little from the position of rest, it would have no tendency whatever to return. The best construction is to make $CD = 0$, that is, to place the three points of action A, C, B, in the same straight line, and to construct the beam so that G, the centre of gravity, shall fall a little below the line A B. The sensibility is then independent of the load, and is simply in the inverse proportion of $W \times CG$; so that by diminishing the weight of the beam, or the distance C G, it may be increased to any required degree. It is supposed that the two arms are precisely of the same length, or that C is placed exactly in the middle between A and B, and also that they are perfectly inflexible.

The conditions now determined from theory must be the guide of the artist in the construction of a good balance. It is of importance that the beam be as light as possible consistent with inflexibility; for not only the inertia, but also the friction, is increased in proportion to the weight, and the sensibility consequently diminished. In order to give lightness and strength at the same time, the beam should be formed of two hollow cones of brass, joined together at the broad ends. A cylinder of steel, passing through the middle of the beam at right angles, forms the axis; and its extremities, ground into sharp edges on the lower side, serve as the points of support. The two edges must be accurately in the same straight line, and turn on smooth planes of agate or polished steel carefully levelled. The scales should likewise be suspended from the extremities of the beam on knife edges, crossing each other at right angles; those in the beam being sharp upwards, and those to which the scales are attached sharp downwards. A needle, or tongue, is usually attached to the beam, pointing directly upwards or downwards when the beam is horizontal, for the purpose of indicating the deviations of the beam from the horizontal position on a graduated scale. It is better, however, to bring the arms to terminate in sharp points, and to place a scale behind each; in this way the slightest flexure of the beam will be rendered evident, if the zeros of the scales are placed exactly in the same level. The scale is indispensably necessary, because the balance, if very sensible, would require a long time to come to rest; but it is known to be poised, when the excursions of the needle

on both sides of the zero of the scale are equal. In order to preserve the knife edges, the beam, when not in use, is supported on rests. Props should also be placed under the scales while loading or unloading the balance. The whole apparatus must be placed under a glass case, to protect it from the disturbing influence of currents of air.

The sensibility of a balance constructed with due care, according to the principles now explained, may be carried to an almost inconceivable extent. There is one in the possession of the Royal Society, made by Ramsden, which weighs ten pounds, and is said to turn with the ten-millionth part of that load, or the thousandth part of a grain. Nevertheless, whatever skill may be employed in the construction, it is plain that the conditions necessary to mathematical accuracy can never be entirely fulfilled. It is impossible to make the two arms of the beam exactly similar, or exactly equal in length. Absolute precision is unattainable in practice. This difficulty, however, may be overcome by the following simple method, imagined by Borda, by which accurate results are obtained independently of extreme precision in the construction of the balance: it is only necessary that it be very sensible. Let P, the substance to be weighed, be placed in the scale A; instead of placing known weights in the scale B, put into it some other substance, for instance bits of iron, chips of wire, or sand, added in minute quantities till the substance P is exactly counterpoised, or the beam becomes exactly horizontal. This being done, let the substance P be gently removed out of the scale A, and let known weights, as grains, be put into it till the substance in the scale B is again exactly counterpoised. It is now of no consequence whether the balance was accurate or not, or whether the body P was exactly equal in weight to the substance against which it was weighed in B. The weight of P must be precisely equal to that of the grain weights; because, under exactly the same circumstances, they both formed a counterpoise to the substance placed in B.

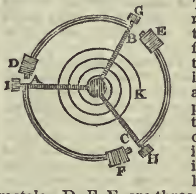
Chinese Balance. This is formed of a slender tapering rod of wood or ivory, about a foot in length. A silk thread passed through a hole perforated nearer one of its extremities than the other serves as the point of suspension. The balance has thus two unequal arms. From the extremity of the shorter a small scale is suspended to hold the substance to be weighed. A sliding weight passes along the other arm, on which divisions are marked; and when the counterpoise is made, the distance of the standard weight from the fulcrum indicates the weight of the substance. In order to procure a greater range, the rod has generally four holes or points of support, at different distances from the extremity, and a corresponding set of divisions is marked on each of its four sides. The principle of this machine is exactly the same as that of the common steel-yard.

The *Danish Balance*, much used in the north of Europe for weighing coarse commodities, is usually formed of an iron bar or a batten of hard wood, having a lump of lead at one of its extremities. The goods are fixed in a hook in the other end; and the whole is suspended through a loop of cord, which is passed backwards and forwards under the rod till equilibrium is obtained. The weight of the goods is then to the weight of the lead reciprocally as their respective distances from the loop.

Roman Balance or *Steel-yard.* *See* STEEL-YARD.

BALANCE OF TORSION. A machine invented by Coulomb for measuring the intensities of electric or magnetic forces, by establishing an equilibrium between them and the force of torsion. Conceive a metallic wire suspended from a fixed point, and kept stretched by a small weight attached to its lower extremity; where also a horizontal needle or lever is fixed, which may be rendered magnetic, or is so formed that one of its ends is a conductor and the other a non-conductor of electricity. The force is brought to act on the extremity of this lever, and its intensity measured by the length of the arc which the needle passes over, reckoning from the point of repose; or an index may be attached to the upper extremity of the wire, and the force measured by the number of degrees through which it can be turned before the lower lever begins to move. The force of torsion is inversely proportional to the length of the wire, and directly to the fourth power of its diameter. The wire must therefore be of considerable length (two or three feet for example), and very fine; and also formed of a substance possessing considerable elasticity. Brass wire is greatly preferable to iron wire; and in some instruments recently constructed a fine thread of spun glass has been used instead of metallic wires, at the suggestion of the late Professor Ritchie. One of the most interesting applications of the torsion-balance was that made by Cavendish to measure the force of attraction of two leaden spheres, in his celebrated experiment to determine the mean density of the earth.

BALANCE OF A WATCH. That part of the machine which, by its inertia, regulates the beat and produces equable motion. It is formed of a wheel or ring, having its weight principally accumulated in its rim, and connected with a spiral spring in such a manner that when drawn aside from the position of rest it acquires an oscillatory motion from the alternate contraction and expansion of the spring. The balance answers the same purpose in watch-work as the pendulum in clock-work, and is affected in a similar manner by variations of temperature. Supposing the length of the spring to remain constant, the time of vibration is directly proportional to the distance of the centre of gyration from the axis of the balance; consequently the duration of the vibration is increased by heat and diminished by cold. To remedy this inconvenience, various contrivances have been applied; but that which is most generally adopted is the *expansion* or *compensation balance*, the principle of which depends on the unequal expansion of two different metals. It may be constructed in the following manner:



The rim consists of two laminæ, the inner of steel and the outer of brass, united by fusion. After being turned to the proper size, the rim is cut in three places, A, B, and C; and one end of each of the parts thus formed being fixed to an arm of the balance, the other is left at liberty to move inwards or outwards according to the variation of the relative lengths of the two metals. D, E, F, are three equal weights placed near the free ends, and which, when adjusted at the proper distances, are fixed in their places by means of screws. Three heavy-headed screws, G, H, I, enter the arms of the balance, and serve to adjust its centre of gravity to the axis of vibration, and also to increase or diminish the mean rate of motion. Now, suppose the balance to receive an increase of temperature, this will tend to lengthen the arms, and consequently to throw the centre of gyration further from the axis, and thereby diminish the velocity of vibration; but as the brass expands more than the steel, the compound bars will at the same time be bent inwards, and the weights D, E, F, thereby thrown nearer the axis, by which the velocity will be increased. When the temperature is diminished, the arms are shortened; but the weights are now thrown to a greater distance from the axis by reason of the contraction of the brass being greater than that of the steel, and the consequent tendency of the compound bars to assume a less curved form. It is easy to see that in so small a machine the adjustment of the parts to procure exact compensation is a matter of great nicety, and requiring much practical skill; in fact, it is only possible to obtain a tolerable compensation by repeated trials.

BALANCE OF POWER. In Politics, a system by which the relative power of different states and alliances is so maintained as to render any extensive derangement improbable. The idea of preserving a balance of power naturally suggested itself to statesmen in ancient Greece, where so large a number of independent states with opposing interests existed on a narrow territory. In Europe, this portion of political science scarcely began to be understood until the 16th century; since which time the maintenance of the balance of power has formed a favourite object, often pursued with unreasonable avidity, by those who have controlled the international relations of Christendom. The great aim of neutral politicians during that century was to establish a balance between the power of France and that of Austria: the latter united with that of Spain became so enormously powerful in the course of it, as to render this an object of great anxiety. But after the commencement of the 17th century the power of France steadily increased, and that of Austria abated. Cromwell's alliance with Mazarin was the last result of the ancient system: for the alliances of Charles II. with the French were for personal objects, and strongly reprobated by all European statesmen. At the end of the 17th century France stood predominant, and it became the great problem of European politics to find a counterpoise to her influence. This was the aim of William III., Eugene, and the Whigs under Queen Anne; and the treaty of Utrecht in 1713, which acknowledged the French supremacy in Spain, was condemned as one of the severest blows ever struck at the balance of power. Nevertheless, this fear, like so many others sedulously cherished by speculative statesmen, proved to have little foundation. The power of France remained stationary during the 18th century, while the forces of Austria, Russia, and Britain increased; and Prussia suddenly arose from a third-rate power to the lowest, but still a respectable position, among the first-rates. During that century the alliances were formed with no very steady regard to the balance of power: France and Austria were usually, but not uniformly, rivals. In 1756, the three great Continental powers were united in a fruitless endeavour to crush the new state of Prussia. The wars of the French revolution entirely altered the ancient

equilibrium; it was restored by the congress of Vienna and the long maintenance of that peaceful arrangement certainly speaks in favour of the sagacity of its constructors. At present Europe is divided, singularly enough, by two different sets of causes, producing different alliances, or rather tendencies towards alliances, for mutual defence. In the first place, the opposition between constitutional and monarchical principles has ranged on the one side Austria, Russia, and Prussia, with their dependent states: on the other, Britain and France, with the Western kingdoms which have liberal governments. In the next place, the interests engendered by purely external politics cause a different line of division. The enormous increase of Russian dominion, particularly towards the East, renders Austria necessarily distrustful, and hostile to the former power. England may be expected to take part with Austria in this quarrel; Prussia, which has no direct interest in the result, will be ranged by position against Austria; while the ultimate decision of France is doubtful, and will in effect determine the struggle.

BALANCE OF TRADE. The term commonly used to express the difference between the value of the exports from and the imports into a country. The balance is said to be favourable when the value of the exports exceeds that of the imports, and unfavourable when the value of the imports exceeds that of the exports. The notion was once entertained that the prosperity of a country depended on exporting merchandise exceeding the value of the imports, and receiving the balance in the precious metals. This mode of estimating the balance of trade, which is evidently founded on the assumption that the precious metals constitute the wealth of a country, has been proved to be completely fallacious, and it is now conceded on all hands that gold and silver are nothing but commodities, whose exportation or importation it is necessary neither to prevent nor encourage by any legislative enactments. But the theory of the balance of trade is not erroneous merely from the false notions which its advocates entertain with respect to money: it proceeds on radically mistaken views as to the nature of commerce. For it will be found that so far from an excess of exports over imports being any criterion of an advantageous commerce, it is directly the reverse; since, were the value of the exports greater than the value of the imports, merchants would lose on every transaction with foreigners, and the trade with them would be speedily abandoned. For a succinct statement and exposition of the errors which were till lately generally prevalent upon this subject, see *M'Culloch's Commercial Dictionary*.

BALANI'NUS. In Entomology, the name applied by Germar to the subgenus of Weevils (*Curculionidæ*), of which the nut grub, or nut weevil (*Balaninus nucum*), is a species. In the perfect insect the rostrum or borer is nearly as long as the body. It is by means of this instrument that the parent weevil drills a hole through the soft shell of the immature filbert, into which she introduces a single brown egg: this is hatched in about a fortnight; and by the time the nut is full ripe, the grub has attained its full growth; it then proceeds to bore a hole with its jaws through the shell, and emerges from the cavity of the nut: falling to the ground it burrows into the earth, and there remains all winter, changing to the proper state, and appearing as a perfect insect in August.

BA'LANITES. (Lat. balanus, *an acorn.*) In Botany, acorn-barnacles, an order of Cirripeds, comprehending those which have a shelly tube, adherent by its base to foreign substances, and closed at its apex by four opercular valves.

BA'LANOPHORA'CEÆ. (Balanophora, one of the genera.) A natural order of Rhiganths, consisting of fungus-like parasitical plants, with small monœcious flowers collected in dense heads arranged upon fleshy receptacles.

BA'LAS RUBY. A term applied by lapidaries to the bright red varieties of the spinel. It is much less rare and valuable than the oriental ruby or red sapphire.

BALAU'STA. In Botany, a kind of fruit having a leathery rind, a superior calyx, and several cells irregularly disposed, with many drupaceous seeds in each.

BALCO'NY. (It. balcone.) In Architecture, a projection from the external wall of a house, borne by columns or consoles, usually placed before windows or openings.

BALDACHI'NO. (It. *a canopy.*) In Architecture, a species of canopy over the principal altar of a church, similar to that at St. Peter's, where it is supported by columns; or that of St. Sulpice at Paris, where it is suspended from above. It succeeded to the ancient *ciborium* (see that word), which was a cupola supported on four columns, still to be seen at many of the altars in Rome. Bernini may claim the merit of its invention. The height of that which he erected in St. Peter's is 128 feet, and being entirely of bronze weighs near 90 tons. It was built by order of the Pope Barberini, from the robbery of the Pantheon, and occasioned the bitter sarcasm — "Quod non fecerunt Barbari, fecerunt Barberini."

BA'LDRIC. (Lat. baldrellus.) A girdle used by the warriors of feudal times: it was often splendidly ornamented, and marked the rank of the wearer.

BA'LDWIN'S PHOSPHORUS. Fused nitrate of lime.

BALEA'RIC CRANE. *See* CRANE.

BALL. (Ger. bal.) Literally, any thing made in a globular form. The word signifies also at once a well-known *divertissement*, and a game familiar in Europe and America. Ball-playing was a favourite amusement among the ancients, who practised it in various ways. They had their hand-ball (*pila trigonalis*), their football (*follis* or *pila paganica*, because played by the rustics), and some other kinds not used by the moderns. In country villas a tennis-court or place for playing ball, called *Sphæristerium*, was usually to be found. (*Sue. Vesp.* 20.) In the middle ages, there were houses appropriated to ball-playing; and in Italy there are still public places where this amusement is practised, and great dexterity displayed.

BALL. In the art Military, any round substance of lead or iron which is discharged from fire-arms, as musket-balls, cannon-balls, &c. The word Ball, with a prefix more or less expressive of its purposes, such as fire-balls, chain-balls, denotes a composition of various ingredients generally combustible. (For an account of these terms see separate articles.) Cannon-balls are made of iron, balls for pistols and fusees of lead. The experiment has been tried of employing iron balls for pistols or fusees, but without effect; as their lightness prevents their flying straight, and they are apt to furrow the barrel of the pistol. As was remarked, cannon-balls are made of cast-iron, and are distinguished as follows by their respective diameters: — Thus the diameter of a

42 lbs. ball is	6·684 inches.			9 lbs. ball is	4·000 inches.		
32	—	6·105	—	6	—	3·493	—
24	—	5·547	—	3	—	2·775	—

BA'LLAD. (It. ballata.) A species of narrative poetry, founded either in history or fiction, displaying the condition and the habits, the tastes and the sentiments of the various nations among whom it is found. The term Ballad is very indefinite in its general acceptation, including classes of composition wholly different in themselves, of which the only common characteristics are brevity of metre and simplicity and perspicuity of style. The opinion entertained by Schlegel of the ballad is, that it is not an original species of composition; but that in general poems of this kind are to be found in the greatest abundance among nations possessed of truly poetical feelings, whose legends, traditions, and national recollections have been interrupted or mutilated by long-protracted civil wars, or by some universal revolution or concussion of opinions. While some authors have assigned the ballad an Arabian, some an Armorican origin, and others have claimed this distinction for the Normans and Provencials, Percy, Bouterweck, and Schlegel concur in awarding to it a Teutonic descent. Be this as it may, it is agreed that the Scandinavian nations delighted, at a very early period, to celebrate in song the deeds of heroes, lovers, knights, &c.; and the three great divisions of the Teutonic poetry of the middle ages — the stories of the Niebelungen, those of Charlemagne (particularly such as relate to his wars against the Arabians, and the battle of Roncesvalles), and the tales of King Arthur's Round Table, consist of what at a later period were called Ballads. Though the name Ballad is Italian, the spirit of chivalry had at no period during the middle ages much dominion or influence on the other side of the Alps; a circumstance that sufficiently accounts for the meagreness of the Italians in this department of poetry. The French too never attained any perfection in the ballad, as their fabliaux, legends, &c. soon degenerated into long prose romances, which were quite destitute of the spirit of the ancient minstrelsy. The Spaniards, on the other hand, are rich in ballads of a highly chivalrous character. These, however, along with some Portuguese ballads which bear infallible marks of a Spanish origin, may with more propriety be classified under the denomination of Romantic Poetry. Among the Welsh, even so early as the 12th century, music and this species of poetry seem to have attained a high degree of excellence; but the ruthless hand of Edward I., by his massacre of the bards, doomed both the one and the other to an almost total annihilation. Of all the species of ballad, the Irish, among other characteristics, appears to be pre-eminently fitted for adaptation to music, as is witnessed in the universally admired "National Melodies" of Thomas Moore. While a variety of opinion exists among the learned as to the nature and requisites of the ballad, it is admitted on all sides that England and Scotland have the honour of possessing a collection of ballads superior to that of every other nation. There

can be little doubt, too, that the home of the English and Scottish ballads is either in the north of England, or in the southern counties of Scotland, as there the influence of the Normans was less than in the south of England. To the proximity, also, of those parts of the two countries where the ballad was cultivated, and the small circle which they embraced, may be attributed the difficulty that exists in assigning to each country its proper share in the collection of ballads. In modern times, if we except the romantic legends of Sir Walter Scott (which can scarcely be denominated ballads), the Germans have cultivated this species of poetry with more success than any other nation; and they can boast of Schiller, Göethe, and Bürger, not only as distinguished poets, but as the revivers of that chivalrous spirit which formed the grand characteristic of our British ancestors. For remarks on the Ballad, vide *Aikin's History of Song; Warton's History of English Poetry; Burney's History of Music; Motherwell's Ancient and Modern Minstrelsy; Jones's Musical and Poetical Relics; Schlegel's Kritische Schriften* (article on Bürger); *Sir W. Scott's Minstrelsy of the Scottish Border; Bishop of Dromore's Collection of Ballads.* (See also the *Conversations Lexicon.*)

BA'LLAST. Is a mass of weighty material placed in the bottom of a ship or vessel to give her *stiffness;* that is, to increase her tendency to return to the upright position when inclined or *heeled over* by the force of the wind or other cause. Ballast consists of shingle (the coarse gravel of the sea-beach), stones, &c. In the royal navy iron ballast alone is used, in pigs of nearly 3 cwt. This has the advantage of lying in small compass; but in consequence of its great weight it tends to give excess of stability, which renders the vessel *uneasy* from the suddenness of the motion: this defect is remedied by *winging* up the ballast, whereby its centre of gravity is raised. For the like reason in stowing the ballast it is tapered to a point at the fore and after extremities. Iron ballast, from its greater cleanliness, is more healthy for the crew than that of other materials. When a ship has no other loading she is said to be *in ballast.*

The quantity of ballast and the mode of its stowage differ greatly in different vessels; and the connection between the motions of a ship and her stowage has not yet been analysed sufficiently to lead to the discovery of direct rules on these important points.

BALL-COCK. A hollow sphere or ball of metal attached to the end of a lever, which turns the stop-cock of a cistern pipe, and regulates the supply of water. As the surface of the water rises in the cistern, the ball is raised by its buoyancy; and as the water descends, it falls by its own weight. The cock is thus closed when the water rises to a certain height, and the supply stopped; but when a part of the water is drawn off from the cistern, the cock is again opened, and the water admitted through the pipe.

BA'LLET. (Fr.) A theatrical representation of actions, characters, sentiments, and passions, by means of mimic movements and dances, accompanied by music. The ballet is divided into three kinds — historical, mythological, and allegorical; and consists of three parts — the entry, the figure, and the retreat. (*Noverre, Lettres sur les Arts imitateurs, et sur la Danse en particulier.*) The chief merit of the ballet lies in an ingenious adaptation of music to the sentiments of the mind as developed in the dance, and in its power of representing every variety of human conduct and emotion, whether of a tragic or comic nature. It has been frequently asserted that the ballet was unknown to the ancients; and yet if the meaning of the Greek term "ὀρχησις" and the Latin term "saltatio" be duly considered, it will be found that both these nations indulged in pantomimic dances of a peculiar kind; the province of gesticulation or of dancing being assigned to one individual, that of declamation to another. (*Xen. Symposion* and *Anab.* vi. 1. 3. 8.) Hence it would appear that the only merit which the moderns can claim in reference to the ballet consists in the substitution of music and scenery in the room of declamation. Be this as it may, it is generally admitted that the ingenious artist Baltazarini, director of music to the princess Catherine de Medicis, first gave its present form to the regular ballet, and that after a considerable interval it was introduced into France. There it continues to flourish like an indigenous plant: while Germany and England, whither it was afterwards transplanted, have not been remiss in fostering its growth. There are many persons who object to the incorporation of the ballet with the opera; and in a few instances, such as the opera "Der Gott und die Bajadere," their objections may be well founded. But assuredly every one who has witnessed the dances introduced into the opera of Guillaume Tell, Robert le Diable, La Tentation de St. Antoine, and Masaniello, must be of opinion that in these cases at least the adoption of the ballet produces a peculiar charm, by enhancing the power and beauty of the representation. (*Conversations Lexicon*).

BALLI'STA. (Gr. βαλλω, *I throw.*) A military engine, used by the ancients for throwing stones, darts, arrows, &c. The Ballista is sometimes confounded with the Catapulta; but a distinction is made by Polybius, who confines the latter term to those machines which throw stones only. The particular mechanism of these engines is not very certainly understood. According to Vitruvius they were made in divers manners; but the principle of all seems to have been the same. A beam of wood or plate of metal is firmly fixed at one extremity; the other extremity is drawn back by means of cords and pulleys; and being suddenly set free, the elastic force with which it seeks to recover itself propels the missiles.

BALLISTIC PENDULUM. An instrument, invented by Benjamin Robins, for measuring the force or velocity of cannon and musket balls. To one extremity of an iron bar is fixed a heavy cubical block of wood, lined at the back with iron. A transverse bar of iron at the other extremity of the first bar serves as an axis of suspension, in which the pendulum swings freely backwards and forwards. The instrument being thus fitted, if the weight of the pendulum be known, and likewise the respective distances of its centres of gravity and oscillation from the axis of suspension, it is easy to determine the quantity of motion that will be communicated to the pendulum by the percussion of a body of a given weight moving with a given velocity and striking it at a given point. Conversely, if the pendulum, when at rest, is struck by a body of a known weight, and the vibration which the pendulum makes after the blow is known, the velocity of the striking body may thence be determined. In order to measure the extent of the vibration, a riband is attached to the lower end of the pendulum, passing loosely through an orifice in a horizontal bar in the frame-work; when the pendulum is raised it draws the riband along with it, and the quantity which thus passes through the orifice measures the chord of the arc of vibration. (See *Robins's New Principles of Gunnery*, vol. i. Prop. 8.; also *Hutton's Mathematical Tracts*, vol. ii.)

BA'LLIUM. In the Architecture of the Middle Ages, the open space or court of a fortified castle. This has acquired in English the appellation Bailey; thus St. Peter's in the Bailey at Oxford, and the Old Bailey in London, are so named from their connection with the sites of castles.

BALLOO'N. (Fr. ballon, *a little ball.*) The name of a machine, which, consisting of an envelope containing a gas specifically lighter than common air, rises into the atmosphere with a greater or less degree of ascensional force. A car, supported by a net-work which extends over the balloon, supports the aëronaut; and a valve, usually placed at the top, to which a string is attached reaching to the car, gives him the power of allowing the gas to escape, and of descending at pleasure.

During the dark ages, and for some time after the revival of science, numerous projects were entertained for navigating the air; but it is only in very recent times, since 1783, that any of them have been realized. The first idea was to employ some mechanical contrivance resembling the wings of birds; but Borelli demonstrated that all attempts on the part of man to fly must necessarily fail, from the utter disproportion of his muscular power to the force that would be necessary to give impulsion to wings of such enormous magnitude as would be required to sustain his weight in the air.

The principle by which a balloon rises in the atmosphere is exactly the same as that which causes the ascent of a cork from the bottom of a vessel filled with water. The weight of the volume of air which it displaces must exceed the weight of the balloon and all that it carries with it. That bodies must rise and remain suspended in a fluid denser than themselves was proved by Archimedes; but the weight of the air is a modern discovery; and it was only in the latter half of the last century that chemistry detected the nature and differences of specific gravities of aëriform fluids. Mr. Cavendish, in 1766, by some ingenious experiments, recorded in the *Philosophical Transactions*, vol. lvi., found hydrogen gas to be from about seven to eleven times lighter than common air, according to the mode of its preparation. In its pure state state it is found to be nearly sixteen times lighter than common air. This substance, therefore, if prevented from diffusing itself, and allowed to obey the force by which it is impelled upwards, will continue to mount till it arrives at a stratum of the atmosphere sixteen times more attenuated than at the surface of the earth. Accordingly, no sooner had Cavendish announced his discovery, than it occurred to Dr. Black that a very thin bag filled with hydrogen gas would mount to the ceiling of a room. Through some imperfection, the experiment when he attempted to execute it failed; and it was several years later before an envelope was thought of sufficiently light, and at the same time impermeable to the gas. Cavallo made a series of experiments on this subject in 1782, but did not succeed in raising any thing heavier than a soap bubble. The expense attending the preparation of the gas probably prevented the experiment from being made on a great scale.

Knowing the specific gravities of atmospheric air, of

the gas with which the balloon is to be filled, and the weight of the envelope in which it is confined, it is not difficult to compute the size the balloon must have in order to rise from the ground, or carry a given weight to a given height in the atmosphere. A globe of air, one foot in diameter, at the level of the sea and under the ordinary pressure, weighs about 1-25th of a pound avoirdupois. An equal globe of hydrogen gas, obtained in the usual way by dissolving iron filings in dilute sulphuric acid, may be assumed (making every allowance for imperfect preparation) to be about six times lighter than atmospheric air; consequently 5-6ths of its whole buoyant force will act in impelling it upwards; that is to say, the force with which a sphere of such gas, one foot in diameter, will tend to rise in the atmosphere will be $\frac{5}{6} \times \frac{1}{25} = \frac{1}{30}$ of a pound avoirdupois. The ascensional forces of different spheres will be proportional to their magnitudes, that is, to the cubes of their diameters; therefore a sphere 12 feet in diameter would rise with a force of 57 pounds, and one of 24 feet in diameter with a force of $8 \times 57 = 456$ pounds. But these determinations must be diminished by the weight of the envelope. The best material for the purpose at present known is thin silk varnished with elastic gum, or Indian rubber. The quantity of this material required to cover a globe one foot in diameter weighs about 1-20th of a pound. Now, for a globe of a greater size, the quantity required will increase with the square of the diameter; hence the covering of a balloon 12 feet in diameter must weigh about 7 pounds, and of one 24 feet in diameter 28 pounds. It follows, therefore, that a balloon of 12 feet diameter will only raise from the ground a weight of 50 pounds, and one of 24 feet 428 pounds. Computing in the same manner, it is found that a balloon 60 feet in diameter would raise a weight equal to about 6950 pounds; and that one of a foot and a half would barely float, the weight of the bag being just equal to that of the imprisoned gas.

The height to which a balloon will rise is determined from the law according to which the density of the atmospheric strata diminishes as the distance from the earth is increased. The buoyant force diminishes with the density; and when it is reduced to a quantity only equal to the weight of the balloon and its appendages, no further ascension can take place. Another circumstance also confines the possible elevation within moderate limits. As the pressure of the external air is diminished, the expansive force of the confined gas becomes greater, and would ultimately overcome the resistance of any material of which a balloon can be made. A balloon quite filled at the surface of the earth would inevitably be torn to shreds at the height of a few miles in the atmosphere, unless a portion of the gas were allowed to escape. For this purpose the balloon is furnished with a safety valve, which can be opened and shut at pleasure; but to prevent unnecessary waste of gas, it ought to be made of such a size that it requires only to be partly filled. A balloon half filled at the surface of the earth would become fully distended at the height of 3½ miles.

We have hitherto spoken only of balloons filled with hydrogen gas; but it is evident that any other substance specifically lighter than air would answer the purpose; in fact, the first balloons by which any one was raised into the atmosphere were not filled with hydrogen, but simply with rarefied air, the rarefaction being produced by kindling a fire under them; and as they thus became filled with smoke, they were called smoke-balloons. The ascensional force, however, which can be gained in this way is not great; besides, the aëronaut must carry a portion of fuel with him for the purpose of maintaining the fire, which adds sensibly to the weight to be raised. The keeping up of the fire is also attended with inconvenience, and even danger.

Two brothers, Stephen and Joseph Montgolfier, proprietors of a paper manufactory at Annonay in France, have the honour of first preparing and sending up a balloon into the air. After one or two previous trials, they announced a public ascent on the 5th of June, 1783. The balloon was prepared of linen cloth; a fire was kindled under it, and fed with bundles of chopped straw. This substance was used with a view to produce a large quantity of smoke. It would seem that they attributed the elevation of the balloon to the ascending power of the smoke, instead of its true cause, the rarefaction of the heated air. In the space of five minutes it was completely distended; and on being let slip, ascended rapidly. It reached an elevation of about a mile, remained suspended ten minutes, and fell at the distance of a mile and half from the place of its ascension. When the news of this experiment was carried to Paris, the surprise was general, and the virtuosi began immediately to consider how it could be repeated. It was determined to apply hydrogen gas on this occasion; and Charles, a celebrated lecturer on natural philosophy, undertook the superintendence of the process. On the 26th of August, 1783, the preparations were complete, and the balloon was transported with much ceremony to the Champ-de-Mars. On the following day, at five o'clock in the afternoon, the report of a cannon announced to the assembled multitude that every thing was ready. "The globe, liberated from its stays, shot upwards, to the great surprise of the spectators, with such rapidity that in two minutes it reached the height of 3000 feet. It traversed successively several clouds, by which it was repeatedly obscured. The violent rain which began to fall at the moment of its ascent did not retard its rapid progress, and the experiment was attended with complete success. The satisfaction was so great that even elegantly dressed ladies remained with their eyes intently fixed on the balloon, regardless of the rain, which fell on them in torrents." (*Libes, Dictionnaire de Physique.*) This balloon remained in the atmosphere only three quarters of an hour; it fell at a distance of about fifteen miles, when it was discovered that a rent was made in its upper part, through which the gas had escaped.

The first adventurers who had courage to undertake an aërial ascent in a balloon, were Pilatre de Rosier, a young naturalist, and the Marquis d'Arlandes. On the 21st of November, 1783, they took their seats in the basket of a smoke balloon; and after rising to an elevation of upwards of 3000 feet, descended safely to the earth. The next ascent was made by MM. Charles and Robert in a balloon filled with hydrogen gas, on the 1st of January, 1784. After a flight of a hour and a half they alighted on the meadow of Nesle, about twenty-five miles from Paris, without the slightest accident. As the balloon still retained a considerable buoyant force, M. Charles resolved on another ascent alone. It rose to the height of near two miles in about ten minutes; and the aëronaut had the satisfaction of seeing the sun, which had set when he left the earth, again rise above the horizon. After remaining about thirty-five minutes in the air he descended safely, at a distance of about nine miles from the spot from which he had risen.

So many aërial voyages executed with safety encouraged other attempts; and no accident occurred till the accomplished Pilatre de Rosier, with his companion Romain, was killed in an attempt to cross the channel from France to England. On the 13th of June, 1785, they ascended from Boulogne. Under the principal balloon, which was of hydrogen gas, they had suspended, for the purpose of increasing or diminishing the ascensional power at pleasure, a smoke balloon, which occasioned the disastrous issue. Scarcely a quarter of an hour had elapsed when the whole apparatus, at the height of 3000 feet, was perceived to be on fire; and the unfortunate voyagers were precipitated to the ground. This calamitous occurrence, however, did not damp the courage of aëronauts. It was obvious that it had been occasioned by the want of proper precautions; accordingly ascents continued to be multiplied, and have since become so common as to be an ordinary spectacle in the principal cities of Europe.

When balloons first began to be constructed, it was expected that they would be found applicable to many important purposes. These expectations have been disappointed, chiefly because it has been found impossible to guide or controul their course. The only power the aëronaut possesses over his balloon is to regulate its elevation within certain limits. In one or two instances they have been successfully used for military reconnoissance. The victory which Jourdan obtained over the Austrians at Fleurus, in 1794, was ascribed to the knowledge obtained of the enemy's movements by means of a balloon. A very interesting ascent was made by Biot and Gay Lussac, in August 1804, and by Gay Lussac alone in September of the same year, with a view to make meteorological observations in the upper strata of the atmosphere. In the first voyage, the two philosophers, at an elevation of between 9,500 and 13,000 English feet, found the oscillations of the magnetic needle to be performed in the same time as at the surface of the earth. At 12,800 feet the thermometer, which stood at 63½° at the observatory, had sunk to 51° of Fahrenheit, being only a decrease of 1° for every thousand feet. The hygroscope indicated increased dryness in proportion to the elevation. In the second ascent, performed by Gay Lussac alone, the variation of the compass, at the height of 12,680, was found to remain unaltered. At 14,480 feet a key held in the magnetic direction attracted with one end and repelled with the other the north pole of the magnetic needle. The same was the case at 20,150 feet. At 18,000 feet the thermometer fell to the freezing point, and at 22,912 feet to 14·9° of Fahr. Two flasks, which had been previously emptied of air, were opened and filled at an elevation exceeding 21,400 feet; and the air brought down from this region was found, on being analysed, to contain exactly the same proportions of the constituent elements as at the surface. The utmost elevation which he reached was 23,040 feet, or four miles and a quarter above the level of the sea, considerably higher than the loftiest peak of the Andes.

Excepting in these two memorable ascents of Gay Lussac, nothing has been gained to science by the use of balloons. The numerous other ascents undertaken, both

before and since, have as yet served no other purpose than to gratify idle curiosity; and from the total failure of every scheme that has been proposed for directing their course through the air, there is little reason to anticipate any great advantages from them to society. Nevertheless, the comparative cheapness and facility with which they can be filled by coal gas, now so generally used for the purposes of illumination, have been the cause of directing public attention again to the subject; and the recent feat of Mr. Green and two companions, who, with a stupendous balloon, and carrying with them a ton of ballast, ascended from Vauxhall in November, 1836, crossed the channel, and, after a journey through the air of eighteen hours, safely descended in the territory of Nassau in Germany, has contributed to revive the hope of rendering balloons available to useful purposes.

BA'LLOT. (Fr. balloter.) A method of voting at elections, &c., by means of little balls, of different colours, which are put secretly into a box, and, when counted, disclose the result of the poll without any discovery by whom each vote is given. The origin of the ballot may be traced to the commonwealth of the Israelites, from whom it was adopted by many eastern nations. The voting by tablets began with the earliest operations of Athenian polity. But it appears questionable whether the ballot at Athens, at least in its more flourishing times, was anything more than a contrivance for securing rapidity of voting, and whether any secrecy was necessarily attached to it. It was employed in judicial proceedings. Secret voting was, however, the custom of the Areopagus. (*Scott on the Athenian Ballot*, 1838.) The same system of voting prevailed also at Carthage, and to this is attributed by Ray (*Travels through Germany and Italy*) the cause of the grandeur and independence of its inhabitants. In the early periods of Roman history, the people voted by word of mouth; and, in creating magistrates, used the form — Consules, &c. nomino, or dico; and it was not until the 614th year of the city, that the Gabinian law, Lex Tabellaria, was introduced, for the purpose, as Cicero alleges (*De Off.* 2. 7.), of giving to the people more liberty in voting. But from this period, as is universally admitted, the practice of bribery made rapid strides; and notwithstanding every effort was made for its suppression by the enactment of penal statutes, such was its success that Julius Cæsar saw himself necessitated to deprive the people not only of the ballot, but even of the right of suffrage. Since the Christian era, the ballot was adopted at a very early period by the Maltese and the Venetians. At Venice, in particular, a most curious and intricate system of voting, consisting of ten previous ballotations, prevailed for the space of 1300 years; and Postellus (in a work *De Magistratibus Atheniensium*) pointedly asserts that the abolition of this practice, combined with other causes, led to the decline of this once flourishing state. Another author, after an elaborate dissertation on the advantages of the Venetian ballot, sums up his account of an election of which he had been an eyewitness in the following words: — "All was easily performed in a short time, without tumult, without noise, without animosities, and the most deserving always elected." In our own times, as is well known, the system of voting by ballot in the election of representatives, magistrates, &c. is adopted in France and America; and, among ourselves, in cases of application for admission into private clubs and societies. Of all controvertible subjects, perhaps there is none which has excited the attention of all political parties so vividly, and formed so large an arena for the display of argumentative skill, as the ballot. While its opponents foresee in its introduction into the public business of this country a tissue of hypocrisy and falsehood, and ultimately danger and ruin to the state, it seems to its supporters to contain the germ of all that is admirable in government and advantageous to the community. Our limits necessarily preclude us from doing more than merely noticing the principal arguments on both sides. The advocates of the ballot, on whom the onus probandi naturally rests, assume as an axiom that the great body of the electors are dependent, and consequently in an unfit condition to give a free and unbiassed vote. On this assumption is hinged not merely the validity, but even the necessity of all their demonstrations in favour of the ballot. The ballot, it is maintained, will not only place the elector on a footing of independence, but will remove all inducement to bribery, as no candidate will choose to offer a bribe when the elector is at liberty to deceive him by giving a secret vote: in a word, that it will annihilate the two species of corrupt influence by which electors are liable to be swayed, — the influence of threats, and the influence of bribes. Nor, as they allege, are their opinions upon this head merely speculative; for they point with triumph to the example of France and America, where the ballot is practised, and where it has long been regarded as the safeguard of the people's liberty. The opponents of the ballot, on the other hand, maintain that, even under the ballot, the canvassing of constituents by candidates would still be practised; in which case, the ballot would prove serviceable only to the dishonest elector, who promises his suffrage to one candidate and votes for another. Moreover, that even here secrecy would be impracticable, as the elector would not only be subjected to a process of the most searching curiosity, but that the landlord would be inclined to visit with more signal marks of his displeasure that tenant on whom his suspicions of deceit should rest, than him who came boldly forward, and voted in the face of day for the candidate of his choice. Again, that even were secrecy practicable (vide *Burke's Reflections*, p. 370.), it would not be desirable. For, as every elector holds his vote for the benefit of the community at large, he is bound to show by an open vote his opinion of the fitness of the candidate for his suffrage: that a secret vote is eminently calculated to counteract the legitimate influence of public opinion, and to lower the standard of political and moral principle, inasmuch as it removes from a public act that responsibility from which no public act ought to be exempted. And lastly, that the argument derived from the practice of France and America can have but little weight, unless it can at the same time be demonstrated that the condition of these countries in other respects is precisely analogous to that of our own: that, as far as America is concerned, vote by ballot was not ingrafted upon its peculiar form of government, but, as in the case of Athens, was coeval with its existence: and that, as regards France, only 200,000 in a population of 33 millions enjoy the elective franchise; and these, from their rank and condition in society, are least likely either to be influenced by intimidation or seduced by bribery. Whether the opponents or the advocates of the ballot have the best of the argument, it is not for us to determine; but one thing is certain, that whether we regard the Athenian or the Roman, the French or the American form of government, it will be found that the people either stipulated for the adoption of the ballot in the original framing of their several constitutions, or, as soon as they ascertained the nature of their rights, insisted on its introduction, from some fancied security it afforded them in the exercise of their privileges. For some apposite remarks on the ballot, see *West. Review* for July 1830; and a Treatise entitled *Reflections on the Ballot*, 1831, Hatchard and Son: see also Montesquieu, *Esprit des Lois*, ii. cap. 20.; and *Ferguson's Roman History*, p. 81.

BA'LSAM OF SULPHUR. Solution of sulphur in olive oil. A brown fetid liquid.

BALSAMA'CEÆ. A natural order of imperfect exogenous balsamiferous trees, related to the Platanaceæ; a species of the only genus, Liquidambar, yields the fragrant resin called storax.

BALSAMINA'CEÆ. (Balsamina, one of the genera.) A natural order of polypetalous Exogens allied to Geraniaceæ. They have irregular flowers, with a spur to one of the sepals, and are chiefly annual-stemmed plants, with a succulent foliage and showy flowers. The common Impatiens nolitangere is a species of this order.

BALSAMODE'NDRON. *See* MYRRH.

BA'LSAMS. Exudations from certain plants, which are liquid or soft solid, and consist of a substance resembling a resin, either combined with benzoic acid or with an essential oil, or both.

BA'LTEUS. (Lat. *a girdle.*) In Architecture, the wide step in theatres and amphitheatres which afforded a passage round them without disturbing the sitters. Nobody sat on it, but it served as a landing or resting place. In the Greek and Roman theatres every eighth step was a balteus. Vitruvius gives the rules for constructing it in the third chapter of his fifth book. The same term is also used by that author to denote the strap which seems to bind the coussinet or cushion of the Ionic capital.

BA'LUSTER. (Said to be from balaustrum, or *βαλαυστιον*, the flower of the wild pomegranate, to the form of which a resemblance is pretended.) In Architecture, a species of small short column, used between piers on the upper parts of buildings, under windows, in balconies, &c. It is quite of modern introduction, that is to say, soon after the revival of architecture. The form of the most ancient that are met with in Florence and other cities of Italy is that of a column, a puerility which has even in these days found admission into some of what are called Greek buildings in this metropolis. Blondel gives rules for proportioning the baluster in its use where the orders are employed.

BALUSTRA'DE. A parapet or protecting fence formed with balusters.

BAMBO'O. An Asiatic genus of arborescent grasses, with hollow jointed stems, and a hardy woody texture. They are externally coated with silex, and sometimes secrete the same substance in the hollows of their stems, when it is called tabasheer. Bamboos grow with great rapidity, and their shoots are cut when young, and boiled like asparagus. They vary in size, according to the

species, from 6 feet to 150 feet in length. When small, they form handles to umbrellas and parasols or walking sticks; when sufficiently large, they are used for the frame-work of Indian cottages, bedsteads, floors, and a variety of domestic purposes. If split into slips, they form bow-strings, and sometimes the arrows discharged from the blow-tubes of the Malays. A few species inhabit the tropical parts of America.

BAMBUSA'CEÆ. A section of the natural order of grasses, comprehending the bamboo as its type.

BAN. A word bearing a variety of significations in the Teutonic jurisprudence and usages, but all apparently connected with the original meaning of "to proclaim, or give public notice." Hence, 1. Ban, the proclamation against an outlaw: *e.g.* the ban of the German Empire, equivalent to ecclesiastical excommunication or declaration of outlawry; whence the words banish, bandits, banditti, and to "ban" or curse; in German bannen, verbannen. 2. The *ban*, in the sense of the national army of a Teutonic people levied by proclamation: hence the French "lever le ban et l'arrière ban" (the latter word being a corruption of *heribannum*, from *heer*, an army). The French ban and arrière ban was levied for the last time in 1672, and commanded by Turenne, but behaved so ill that this feudal armament was thenceforth discontinued. 3. The *banns* of marriage, being notice given by public proclamation to the parish of the intended solemnization. In the Sclavonic tongues ban means master: the lords of some of the frontier provinces of Turkey were so styled; hence the *bannat* or lordship of Temeswar, now belonging to Austria.

BANA'NA. A tall herbaceous endogenous plant, the *Musa sapientum* of botanists, having broad convex leaves with fine oblique veins, and growing in a tuft from the top of a stem formed by the union of the broad bases of the leaves. The fruit ripens in succession in large clusters weighing many pounds; it is of the same nature as the plantain (*quod vide*). It is a native of the West Indies, where it contributes essentially to the food of the better classes.

BA'NCHUS. A Fabrician genus of Hymenopterous insects, of the tribe *Pupivora*, and family *Ichneumonidæ*; characterised by long threadlike antennæ, abdomen compressed at the extremity, ovipositor not extended. Of this genus there are five British species, which, like the rest of the family, are parasitic in the larva state, feeding on the bodies of other insects.

BA'NCO. In commerce, a word of Italian origin, signifying a bank, and commonly employed to describe the bank of Venice. Banco is also used to distinguish banco money from current money at Hamburg, &c. *See* EXCHANGE.

BA'NCO. In Law, superior courts of common law are said to sit in banco during term, the judges occupying the bench of their respective courts. *See* COURTS OF LAW.

BAND. (Fr. bande.) In Architecture, a term used to denote what is generally called a face or fascia. To speak correctly, it signifies a flat, low, square, profiled member, without respect to its place. That member in a cornice on which modillions or dentils are cut is called the modillion band in the former, and the dentil band in the latter case.

BA'NDED. (Lat. fasciatus.) When any body is striated across with coloured bands.

BANDI'TTI. (It.) Persons *declared* to be banished, exiled, or outlawed. (Horne Tooke.) At the present time, bandit and robber are nearly synonymous terms. The Italian bandits formed a peculiar class, and were frequently employed by the petty princes and grandees in executing their projects either of love or ambition. As late as the year 1820, they were frequently employed as escorts; and in their case the proverb "honour among thieves" was amply verified, for, on the payment of a stipulated sum, travellers might repose in them unlimited confidence.

BANDOLE'ER. In ancient Military History, a large leathern belt worn over the right shoulder, and hanging under the left arm, to carry military weapons. The term is also applied to small leather cases, of which each musketeer wore twelve, hanging upon a shoulder-belt: each of these contained the charge of powder for a musket. They are disused, but may be seen in the armoury in the Tower.

BA'NIANS. A peculiar class among the Hindus, whose office or profession is trade and merchandise. In this sense Banians stand contradistinguished from Brahmins, Cuttery (Eschatryá), and Wyse (Vaisyá), the three other castes into which the Indians are divided. (See Gemelli Carreri, and Sir W. Jones.) They are scattered over the whole of Asia, and have appropriated to themselves the sole management of traffic in the East. They retain every where their native language and religion (the doctrine of the Metempsychosis); and are distinguished by their honesty, fidelity, and goodnature.

BA'NISHMENT. "Expulsion from any country, province, or town, by the judgment of some court or competent authority." Banishment as a species of punishment has been practised by all governments, both ancient and modern. Among the Greeks two kinds of banishment were in use: φυγη, which involved confiscation of property, and was inflicted only upon those convicted of certain crimes; and, at Athens, *ostracism*, by which persons were banished on mere suspicion that their power or riches might prove subversive of liberty. The Romans made use of three kinds — *relegatio*, *exilium*, and *deportatio*, — which involved various grades of punishment; the last, however, being the most severe, as it subjected the delinquent to the confiscation of his property, and the loss of his rights as a Roman citizen. The *second* was introduced by the Emperor Augustus, and formed the kind of banishment to which, among others, Ovid was condemned. During the first French revolution, banishment (*deportation*) was substituted for the guillotine, and towards the end of Robespierre's administration became very general. It still forms part of the French code, where it is classed in the third degree of infamous punishments, and gives rise to civil death. As a criminal punishment banishment was unknown to the ancient unwritten law of England, although voluntary exile was often adopted in order to evade legal prosecution. It was first towards the end of Queen Elizabeth's reign that a statute was enacted which condemned persons convicted of certain delinquencies to leave the town or village where they lived; but it was at a much later period that the punishment of *transportation* (*quod vide*) was legalised by parliamentary statute. In Germany, numerous instances have recently occurred of persons convicted of treasonable practices having had their sentence commuted into perpetual banishment; and in the universities of the same country this punishment (*relegatio*) is inflicted upon those who are convicted of a gross infringement of the academical laws, and involves the forfeiture of all right to enter upon a professional career.

BANISTERIEÆ. (Banisteria, one of the genera.) That division of Malpighiaceous plants in which the fruit is samaroid, not baccate, and analogous to what is found in Aceraceæ.

BANK. In Natural History, an elevation of the ground. Banks at sea are indicated by a decrease of the soundings, and sometimes by the elevation of the land above low-water mark. Of these, one of the largest and best known is the great bank of Newfoundland, famous for the resort of cod-fish.

BANK. In Commerce, an establishment for the custody and issue of money. The individual who manages a bank, or who carries on the business of banking, is called a banker.

Banks are of various kinds; some confining themselves entirely to the custody and issue of the money deposited in their hands by their customers, while others issue notes or paper money of their own. They are sometimes conducted by private individuals, and sometimes by companies consisting of an indefinite number of persons.

Utility of Banks. — Notwithstanding the precious metals are, in many respects, admirably fitted to serve as a medium of exchange (*see* MONEY), they have two very serious drawbacks, — their cost, and the difficulty and expense of carrying them from place to place. If the currency of Great Britain consisted only of gold, it would amount to at least sixty millions of sovereigns; and the expense attending such a currency, allowing only ¼ per cent. for wear and tear and loss of coins, could not be reckoned at less than 3,250,000*l.* a year. The weight of 1000 sovereigns exceeds 21 lbs. troy; so that were there nothing but coins in circulation, the conveyance of large sums from place to place to discharge accounts would be a very laborious process, and even small sums could not be conveyed without considerable difficulty; hence it is that most commercial and highly civilised nations have endeavoured to fabricate a portion of their money of less costly and heavy materials, and have resorted to various devices for economising the use of coin. Of the substitutes for coin hitherto suggested, paper is, in all respects, the most eligible. Instead of discharging their debts by a payment of the precious metals, individuals, on whose solvency the public may rely, pay them by giving a bill or draft for the sum, payable in coin at sight, or at so many days after date; and as this bill or draft passes currently from hand to hand as cash, it performs all the functions of coin, while it saves its expense to the public. A sense of the advantages that might be derived from the circulation of such bills or drafts led to the institution of banks for their regular issue.

By a bank of this description, or a bank of circulation, is meant an establishment founded by one or more individuals, known or believed to be possessed of large property, for the accommodation of the public with loans. A banker, on being applied to for a loan, does not make the advance in gold or silver, or other valuable material, but in his own promissory notes or engagements, binding him to pay the sums specified in them at

sight, when presented at the bank, or at some specified period. When a bank is in good credit, its notes are deemed by the public equivalent to a corresponding amount of gold or silver; and, being freely accepted in payment of debts of all sorts, and easily carried about or conveyed by post, they are even more useful to those who originally borrowed them from the bank, and to their subsequent holder, than an equal sum in coin. The borrowers, therefore, do not scruple to pay the same interest for the loan of a promissory note of 100*l.* or 1,000*l.* that they would do for the loan of a hundred or a thousand sovereigns. But the note costs the issuer comparatively little. He, in fact, deals in credit, or in obligations to pay, and not in real values; his profits consisting in the excess of interest derived from the notes or obligations he has issued over and above the interest of the cash or unproductive stock he is obliged to keep in his coffers to meet the demands of the public for payment of his notes, and the expenses of his establishment.

Besides this sort of bank, there are also banks of deposit, or banks for keeping the money of individuals. A merchant, or other person, using a bank of this sort, makes all his considerable payments by drafts upon his bankers, and sends all the bills due to him to them to be presented, and noted, if not duly paid. By this means he saves the trouble and expense of keeping a quantity of unemployed money at home, of receiving coins or notes that are not genuine, and of making any mistakes with respect to the presentation of due bills; and in consequence of the saving of money that is thus effected, a much less quantity serves for the demand of the public.

If a bank of circulation, or an establishment for the issue of notes, fall into discredit, its notes must obviously cease to circulate. Unless when guaranteed by government, or made legal tender, no one ever takes promissory notes, except on the supposition that they will be paid when presented or when due, and that they are substantially equivalent to cash. The moment any suspicion (whether well or ill founded is so far of little consequence) arises that the issuers of notes are unable to meet their obligations, there is a run upon them for payment, and their notes are rejected by every one.

All banks of circulation are necessarily almost at the same time banks of deposit; but there are in all civilised and commercial countries a good many of the latter class of banks only. Banks of deposit derive their profit either from their paying no interest on the sums deposited in their hands, as is the case with most of the London banks; or from their paying a less rate of interest on deposits than that for which they lend them to the public, as is the case with the Scotch banks.

English Banks. — Banking establishments for the issue of notes, and for taking care of other people's money, have existed in this country since the latter part of the seventeenth century. The Bank of England was founded in 1694, and has long been the greatest bank of circulation and deposit in the world. It grew out of a loan of 1,200,000*l.* for the public service, for which (such was the low state of public credit at the time) the subscribers were to receive 8 per cent. interest, with 4,000*l.* a year as the expense of management, and be incorporated into a banking company, denominated the Governor and Company of the Bank of England. The charter was granted for ten years; and it has since been prolonged by various renewals till the 1st of August 1845. The loans made by the bank to government were gradually increased, till in 1800 they amounted to 14,686,000*l.* But at the last renewal of the charter in 1833, a fourth part of the standing debt due to the bank was paid off, making the sum now (1838) due by the public to that establishment, exclusive of advances on account of dead weight and other public securities, 11,047,750*l.*

From its foundation the bank has enjoyed several peculiar privileges. The principal of these was conferred upon it in 1708, by an act which prohibited any company from being established for the issue of notes payable on demand in England and Wales with more than *six* partners. This restriction continued till 1826, when it was abolished, in so far as respects all places more than 65 miles distant from London; but within that distance it still prevails.

The Bank of England is, and always has been, the goverment bank, transacting for it all the banking business of the nation, receiving the produce of the taxes, loans, &c.; and paying the interest of the public debt, the drafts of the treasury and other public departments, transferring stock, &c. For this the bank has received since 1834, exclusive of the use of the balances of the public money in her hands, about 130,000*l.* a year.

In consequence of its employment by the government, of the restriction confining the number of partners in other banks to *six*, and of its great capital and credit, Bank of England notes have always been held in the highest estimation; and no bank for the issue of promissory notes payable on demand has been established in or near London. In the provinces, however, numerous *private* banks (that is, banks with not more than *six* partners) of issue and deposit have always existed. In 1792, their number is supposed to have exceeded 350. Many were destroyed by the revulsion of that year; but subsequently to 1800 they began rapidly to increase. In 1809, they amounted to 782; and in 1814, when most numerous, to 940. Since the abolition of the restriction on the number of partners, in 1826, many banks have been established; some with very large bodies of proprietors. Except in the case of the Bank of England, all the holders of stock in the other English banks are liable not merely for the amount of of their share in the capital stock of the company, but for its whole debts, whatever may be their amount. All notes are made payable on demand; and since 1826 no notes for less than 5*l.* have been allowed to circulate.

From the first establishment of the Bank of England, down to 1797, it had always paid its notes regularly when presented. But in the course of 1796, and the early part of 1797, there was, owing to the prevalence of reports of invasion, a pretty severe run upon the Bank of England, and it was at length apprehended that she might be obliged to make a temporary stoppage. To avert a contingency of this sort, an order in council was issued in February, 1797, authorising the bank not to pay her notes in gold; and this order was subsequently confirmed by parliament, and prolonged till after the conclusion of a definite treaty of peace.

Contrary to what might have been and was anticipated by many, the order referred to did not stop the circulation of Bank of England notes, or diminish the confidence of the public in that establishment. The report of a committee of the House of Commons, published soon after the suspension, showed that the bank was not merely possessed of the most ample funds to meet all her engagements, but that she had a surplus stock, after all demands upon her were deducted, of no less than 15,513,000*l.* This report, and the fact that Bank of England notes became practically legal tender, secured their circulation.

The obligation on the issuers of paper to pay their notes on demand is necessary, not only to give them circulation, but to prevent their being issued in excess; for as soon as any considerable over-issue takes place, the currency becomes depreciated as compared with that of other countries, and notes are, in consequence, returned upon the banks for payment, in order to get gold and silver to send abroad, where their value is higher; and the banks, to obviate the drain, are obliged to narrow their issues. London being the centre where the exchanges with other countries are adjusted, the value of its currency determines the state of the exchange; and it ultimately also determines the value of the currency of the provinces, there being a constant demand upon the country banks for gold or bills on London. While the Bank of England was obliged to pay in specie the value of her notes could not, and in point of fact did not, differ materially from that of gold. But in 1799, or 1800, after the check of cash payments was removed, they began to be depreciated, partly in consequence of their own over-issue, but far more through the over-issue of the paper of the country banks. The latter were multiplied to an unprecedented extent. It is of importance, too, to observe that previously to 1797 neither the Bank of England nor any of the country banks issued notes for less than 5*l.*; but both parties having commenced their issue in the course of that year, a new outlet was opened for the emission of paper that was particularly accessible to the country bankers. And such was the eagerness of the greater number of the latter to get their paper afloat, that individuals who could barely afford to buy stamps for bills frequently succeeded in getting the command of immense sums; and, as they had nothing of their own to lose, boldly ventured on the most hazardous speculations. During the last half dozen years of the war the depreciation of paper resulting from the circumstances now glanced at was such, that the ounce of standard gold, which should be worth only 3*l.* 17*s.* 10½*d.*, was, in 1814, actually worth 5*l.* 4*s.*, being a depreciation of 25¼ per cent.

The difficulties which had been thrown during the latter years of the war in the way of importation from abroad, combined with deficient crops at home, caused an extraordinary rise in the price of corn. But no sooner had the northern ports been opened, in the autumn of 1814, than a large importation, accompanied by a heavy fall of prices, began to take place; which was still further increased after the general pacification in 1815. This fall proved ruinous to many farmers, who had been large borrowers from the country banks. In consequence of the losses arising from this and other causes that grew out of the altered situation of the country, a want of confidence was experienced; and the country banks being generally without the means of meeting any emergency, no fewer than 240 of these

establishments stopped payment. There is, in fact, believed to have been, in 1814, 1815, and 1816, a greater destruction of bank paper in this country, and a wider range of bankruptcy, than had ever previously taken place any where else, except perhaps in France at the breaking up of the Mississippi scheme. The contraction of the currency that had been thus violently brought about raised its value nearly to par, and paved the way for the act of 1819, the 59 G. 3. c. 78., commonly called "Peel's Act," from its being introduced by Sir Robert Peel, which provided for the return to cash payments by the Bank of England at the old standard. These were resumed in 1821.

The policy of the act of 1819 was much questioned at the time, and since; but it has been successfully vindicated over and over again. But admitting that when enacted it might, in some respects, be objectionable, that would add nothing to the plea of those who still continue to urge its repeal. The restored standard has now (1838) been maintained for nearly twenty years; and 99 out of every 100 of the existing contracts have been entered into with reference to it. To set it aside would not be to repair former injustice, if such were committed, but to commit it afresh — to perpetrate an abuse in 1838 for no better reason than that it is alleged that a similar abuse had been perpetrated in 1819! So long as there is either common sense or common honesty in parliament, we are pretty secure against an attempt of this sort succeeding.

Notwithstanding that the bankruptcy which overspread the country in 1814, 1815, and 1816, was mainly ascribable to the defective constitution of the country banks, and to the reckless and improvident manner in which they were managed, no steps were taken when the resumption of cash payments was decided upon in 1819 to obviate any one of these sources of mischief. The consequences were such as might have been anticipated. A peculiar combination of circumstances having conspired to produce an extraordinary rage for speculative undertakings in 1824 and 1825, the country bankers gave in to the infatuation, and made the most sudden and excessive additions to their issues. In consequence the currency became redundant; and this having occasioned a heavy drain for gold on the Bank of England, the latter was, in the end, obliged to contract her issues. The country banks, whose engagements had in many instances been carried to an extent quite incommensurate with their capital, began to give way the moment they experienced an increased difficulty of obtaining pecuniary accommodation in London; and so rapid and sweeping was the destruction, that in less than six weeks above seventy banking establishments were swept off, and a vacuum created in the currency that absorbed from *eight* to *ten* millions of additional issues by the Bank of England!

This catastrophe seems at length to have satisfied the parliament and people of England that the private banking system was weak and vicious, and that it was imperatively necessary it should be amended and strengthened. In this view the clause in the act of 1708 already referred to, prohibiting any private bank from having more than *six* partners, was repealed; and the issue of notes for less than 5*l*. was also forbidden.

The last measure has, no doubt, shut up one of the easiest channels through which the inferior order of country bankers used to get their paper into circulation, and has been in so far advantageous. But abundance of other channels are still open to them; and the fact that a third part of all the private banks existing in England and Wales in 1792 were destroyed during the revulsion of that year, though no notes for less than 5*l*. were then in circulation, shows how little the suppression of small notes can do to obviate the mischiefs complained of. Very important advantages were, however, expected to result from the other measure, or that repealing the act of 1708, and consequently allowing the formation of joint stock banks, or banks with any number of partners. But these anticipations have proved to be nearly, if not quite, fallacious. There cannot, in fact, be a greater error than to suppose that because a bank has a considerable number of partners it will necessarily be either rich or well managed. It may be neither the one nor the other. A single individual may possess more wealth than a number of individuals associated together; and the chances are, that if he engage in banking, or any other business, it will be better managed than by a company. Under our present system, and in fact it is impossible to prevent it under any system, the partners in joint stocks, or in other banks, may be men of straw, or persons without property, and unable to fulfil their engagements. It is of the essence of a secure and well established paper currency that the notes of which it consists should be of the exact value of the gold or silver they profess to represent, and that, consequently, they should be paid the moment they are presented. But it is not enough to order that this condition shall be uniformly complied with. Such order is obeyed only by the opulent, prudent, and conscientious banker, and forms little or no check on the proceedings of those of a contrary character. It is the latter class, however, that it is especially necessary to look after; and it is needless to say that any system that permits notes to be issued without let or hindrance by speculative, ignorant, or unprincipled adventurers, must be essentially vicious.

The progress of the system of joint stock banking, or of banks with more than *six* partners, since 1826, when it commenced, has been as follows: —

		Banks.			Banks.
In 1826 were registered		3	In 1833 were registered		9
1827	—	4	1834	—	10
1828	—	0	1835	—	9
1829	—	7	1836	—	45
1830	—	1			
1831	—	9			104
1832	—	7			

In point of fact, however, the joint stock banks have each at an average from five to six branches; and as these branches transact all sorts of banking business, and enjoy the same credit as the parent establishment, from which they are frequently at a great distance, they are to all intents and purposes so many distinct banks. Hence, instead of 104, there were really above 500 joint stock banks in England and Wales in 1836, of which no fewer than 200 were opened in the course of that year! Some private banks have latterly been converted into joint stock banks, and others have wound up their affairs and ceased to exist; still, however, their number amounts to about 550; so that, in all, there are at this moment nearly 1,100 joint stock and private banking establishments in England and Wales. From a half to two thirds of these establishments issue notes.

Previously to 1833, the notes of the country banks were made payable in gold; but it was then enacted that they might be paid either in gold or Bank of England notes, at the option of the issuers. Bank of England notes are now, in fact, legal tender everywhere except at the bank and her branches.

The dividends on Bank of England stock from 1767 to the present time have been—from 1767 to 1781, 5½ per cent. per annum; from 1781 to 1788, 6 per cent.; from 1788 to 1807, 7 per cent.; from 1807 to 1823, 10 per cent.; and from 1823 to 1838, 8 per cent. The dividends are exclusive of the sums occasionally advanced as *bonuses:* the latter amount since 1799 to 3,783,780*l*. over and above an increase in the capital of the bank in 1816, which amounted to 2,910,600*l*.

Defects in our present Banking System — Suggestions for its Improvement. — The issue of notes is of all businesses that which seems to hold out the greatest prospect of success to the schemes of those who attempt to get rich by preying on the public. The cost of engraving and issuing notes is but an inconsiderable item compared with the sums for which they are issued; and provided they get into any thing like extensive circulation, they become, at once, considerably productive. They are not issued, except on the deposit of bills or other securities yielding a considerable rate of interest; so that if an individual, or set of individuals, with little or no capital, contrive, by fair appearances, promises, and similar devices, to insinuate himself or themselves into the public confidence, and can maintain 20,000*l*., 50,000*l*., or 100,000*l*. in circulation, he or they secure a good income in the meantime; and when the bubble bursts, and the imposture is detected, they are no worse off than when they set up their bank. On the contrary, the presumption is that they are a great deal better off; and that they have taken care to provide, at the cost of the credulous and deceived public, a reserve stock for their future maintenance: hence, seeing the facilities for committing fraud are so very great, the propriety, or rather necessity, of providing against them.

It has sometimes been contended, in vindication of our present system, which allows any individual or set of individuals, how bankrupt soever in fortune and character, to issue notes without check or limitation of any kind other than the promise to pay them on demand, that they are essentially *private paper;* that the accepting of them in payment is optional; and that as they may be rejected by every one who either suspects or dislikes them, there is no room or ground for interfering with their issue! But every body knows that whatever notes may be in law, they are in most parts of the country *practically and in fact legal tender*. The bulk of the people are totally without power to refuse them. The currency of many extensive districts consists in great part of country notes; and such small farmers or tradesmen as should decline taking them would be exposed to the greatest inconveniences. Every one makes use of or is a dealer in money. It is not employed by men of business only, but by persons living on fixed incomes, —women, labourers, minors; and in short by every class of individuals, very many of whom are necessarily, from their situation in life, quite unable to form any estimate of the

solidity of the different banks whose paper is in circulation. Such parties are uniformly severe sufferers by the failure of banks. The paper that comes into their hands is a part of the currency or money of the country; and it is quite as much a part of the duty of government to take measures that this paper shall be truly and substantially what it professes to be, as that it should take measures to prevent the issue of spurious coins or the use of false or deficient weights and measures.

Now it will be found, should the circulation of provincial notes be allowed to continue, that there is but one means of making sure of the solvency of the issuers, and of providing for their being paid when presented; and that is, by compelling all issuers of such notes to give security for their payment. This, and this only, will hinder the circulation of spurious paper, and afford a sufficient guarantee that the notes the public are obliged to take are really and in fact what they profess to be. The measure, too, is one that might be easily enforced. To carry it into effect, it would merely be necessary to order that all individuals or companies, on applying for stamps, should be obliged, previously to their obtaining them, to lodge in the hands of the commissioners an assignment to government stock, mortgages, landed or other fixed property, equivalent to the amount of the stamps issued to them, to be held in security for their payment.

It has been objected to this plan, that it would be injurious, by locking up a portion of the capital of the banks; but this is plainly an error. Its only effect in this respect would be to force such banks as issued notes to provide a supplemental capital, as a security over and above the capital required for conducting their business. But this supplemental capital would not be unproductive. If it consisted of lands, the owners would receive the rents; and if it consisted of government securities, they would receive the dividends or interest due upon them, precisely in the same way that they are received by other persons; while the fact being known that they possessed this supplemental capital, or that they had lodged security for the payment of their notes, would, by giving the public perfect confidence in their stability, enable them to conduct their business with a less supply of floating or immediately available capital than would otherwise be necessary.

It is absurd to object to this plan on the ground of its interfering with the private pursuits of individuals. It is the duty of government to interfere to regulate every business or pursuit that might otherwise become publicly injurious. On this principle it interferes to prevent the circulation of spurious coins, and of notes under a certain sum and not payable on demand; and on the same principle it is called on to interfere to prevent the act ordering the payment of notes becoming again, as it has very frequently done already, a dead letter, by making sure that it shall be complied with. The interference that would take place under the proposed measure is not only highly expedient, but would be of the least vexatious kind imaginable. All that is required of the persons applying for stamps for notes is, that they should deposit in the hands of the commissioners a certain amount of exchequer bills, or other available securities, according to their demand for stamps. They are not asked to state how they mean to dispose of these stamps, — to whom or in what way they are to be issued. They are merely required to give a pledge that they shall be paid, or that they shall not be employed, as so many others have been, to deceive or defraud the public. It is little else than an abuse of language to call this an interference with private affairs.

The taking of security in the way now suggested, from the issuers of notes, would effectually provide for their payment when presented. Adventurers without capital, and sharpers anxious to get themselves indebted to the public, would find that banking was no longer a field on which they could advantageously enter. Notes would be made, in fact as well as in law, equivalent to the specie they profess to represent; and the paper currency would acquire a solidity of which it is at present wholly destitute.

But though the plan of taking security would completely obviate the risk of loss from the circulation of worthless paper, or of paper issued by parties without the means, and probably also the inclination to pay it on presentation, it would not touch another abuse inherent in the present system; that is, it would leave the currency exposed, as at present, to all those constantly recurring fluctuations in its amount, those alternations of glut and deficiency, by which it has been affected since provincial banks became considerably multiplied, and which are in the last degree injurious. A paper currency is not in a sound or wholesome state, unless, 1st, means be taken to insure that each particular note or parcel of such currency be paid immediately on demand; and unless, 2nd, *the whole currency vary in amount and value exactly as a metallic currency would do were the paper currency withdrawn and coins substituted in its stead.* The last condition is quite as indispensable to the existence of a well-established currency as the former; and it is one that cannot be realised otherwise than by confining the issue of paper to a single source.

It is supposed by many that there can be no greater fluctuations in a paper than in a metallic currency, provided the paper rest on an undoubted basis, and be regularly paid the moment it is presented. But this is an error. Wherever there are numerous issuers, there may be, and the chances are fifty to one there will be, perpetually recurring fluctuations in the amount and value of the currency. An over-issue of convertible paper is not, of course, indicated by any difference between the value of such paper and gold at home; but it is indicated by a fall of the exchange, and by an efflux of bullion to other countries. If paper were only issued by the Bank of England, or some one source in London, and then only in exchange for bullion, the currency would be in its most perfect state, and would fluctuate exactly as it would do were it wholly metallic. But at present it is quite otherwise. The currency is supplied by hundreds of individuals and associations, all actuated by different and frequently conflicting views and interests. The issues of the Bank of England, though not always are generally governed by the state of the exchange, or rather by the influx and efflux of bullion, increasing when it flows into and decreasing when it flows out of the country. But it is quite otherwise with the provincial bankers. Their issues are not regulated by any such standard, but by the state of credit and prices in the districts in which they happen to be situated. If their managers suppose that these are good or improving, they rarely hesitate about making additional issues. Hence, when the state of the exchange and the demand on the Bank of England for bullion show that the currency is redundant, and ought to be contracted, the efforts of the bank to effect its diminution are often impeded, and met by a contrary action on the part of the country banks. This is not owing to the ignorance of the latter. Under the supposed circumstances, the country bankers see, speaking generally, that they ought also to contract; but being a very numerous body, comprising several hundred establishments scattered over all parts of the country, each is impressed with the well-founded conviction that all that he could do in the way of contraction would be next to imperceptible; and no one ever thinks of attempting it, so long as he feels satisfied of the stability of those with whom he deals. On the contrary, every banker knows, were he to withdraw a portion of his notes, that some of his competitors would most likely embrace the opportunity of filling up the vacuum so created; and that consequently he should lose a portion of his business, without in any degree lessening the amount of paper afloat. Hence, in nineteen out of twenty instances, the country banks go on increasing their aggregate issues long after the exchange has been notoriously against the country, and the Bank of England has been striving to pull up.

The circumstances now stated were strikingly exemplified in the course of 1836 and the early part of 1837. The excessive multiplication of joint stock banks in 1836, the great additions they made to the number of notes afloat, and the still greater additions they made to the number of bills, checks, and other substitutes for money, occasioned a redundancy of the currency, a fall of the exchange, and a drain upon the Bank of England for gold. But while the latter was narrowing her issues, by supplying the exporters of bullion with gold in exchange for notes, the country banks went on increasing their issues! What the former did by contracting on the one hand, the latter more than undid by letting out on the other. The vacuum created by the withdrawal of Bank of England paper was immediately filled up, and made to overflow by the issue of a more than equal amount of provincial paper; so that had it not been for the rise in the rate of interest, and the other repressive measures adopted by the bank, the probability is that she might have gone on paying away bullion for notes till she was drained of her last sixpence, without in any degree affecting the exchange. But this is not all. Not only do the country banks almost universally increase their issues when they ought to be diminished, but the moment they are compelled to set about their reduction they run headlong into the opposite extreme, and unreasonable suspicion takes the place of blind unthinking confidence. The cry of *sauve qui peut* then becomes all but universal. It is seldom that a recoil takes place without destroying more or fewer of the provincial banks; and, provided the others succeed in securing themselves, little attention is usually paid to the interests of those they have taught to look to them for help.

We have previously noticed the bankruptcy and distress entailed on the country by the over-issue and consequent failure of the country banks in 1814, 1815, and 1816, and again in 1825—26. The influence of the revulsion in 1792 was similar, and equally disastrous; and though, owing to the assistance afforded by the Bank of England, the crisis of 1836 was very much mitigated, it

seriously affected the industry and commerce of the empire, and inflicted a blow upon them both from the effects of which they have not as yet (1838) recovered.

Although, therefore, the exacting of security for their payment from the issuers of notes would protect the holders from loss, and be in so far advantageous, it would not hinder that competition among the issuers that is so very injurious, nor prevent the supply of paper being at one time in excess and at another deficient. If we would provide for that unity of action on the part of the issuers, and that equality in the value of money, that are so indispensable, it must all emanate from one source. Were one body only entrusted with the issue of notes, it would be able immediately to narrow the currency when bullion began to be exported, and to expand it when it began to be imported; and it would be easy for the legislature to lay down and enforce such regulations as would effectually prevent the fluctuations in the amount and value of the currency ever exceeding those that would take place were it wholly metallic. But nothing of the sort need be expected so long as it is supplied by more than one source. Everything must then be left to the discretion of the parties. And it will certainly happen in time to come, as it has invariably happened in time past, that some of them will be increasing their issues when they should be diminished, and diminishing them when they should be increased; and that the country will continue to be exposed to the incessant recurrence of the most destructive revulsions.

Statement of the Affairs of the Bank of England, February 29. 1832.

Dr.		
To bank notes outstanding - -		L 18,051,710
To public deposits, viz.—		
Drawing accounts - -	2,034,790	
Balance of audit roll - -	550,550

Scotch Banks. — The act of 1708, preventing more than six individuals from entering into partnership for carrying on the business of banking, did not extend to Scotland. In consequence of this exemption, several banking companies, with numerous bodies of partners, have always existed in that part of the empire. The Bank of Scotland was established by act of parliament in 1695. By the terms of its charter it enjoyed, for twenty-one years, the exclusive privilege of issuing notes in Scotland. Its original capital was only 100,000*l.*; but it was increased to 200,000*l.* in 1744, and now amounts to 1,500,000*l.*, of which 1,000,000*l.* has been paid up.

The Royal Bank of Scotland was established in 1727. Its original capital was 151,000*l.*; at present it amounts to 2,000,000*l.*, which has been all paid up.

The British Linen Company was incorporated in 1746, for the purpose, as its name implies, of undertaking the manufacture of linen. But the views in which it originated were speedily abandoned, and it became a banking company only. Its paid up capital amounts to 500,000*l.*

Exclusively of the above, there are two other chartered banks in Scotland: the Commercial Bank, established in 1810; and the National Bank of Scotland, established in 1825. The former has paid up capital of 600,000*l.*, and the latter of 500,000*l.*

None of the other banking companies established in Scotland are chartered associations; and the partners are jointly and individually liable to the whole extent of their fortunes for the debts of the firms. Some of them, as the Aberdeen Town and Country Bank, the Dundee Commercial Bank, the Perth Banking Company, &c., have very numerous bodies of partners. Generally speaking, they have been eminently successful. An original share, 150*l.*, of the stock of the Aberdeen Banking Company, established in 1767, is now (1838) worth no less that 2,500*l.* Their affairs are uniformly conducted by a board of directors chosen by the shareholders.

There are very few banks with less than six partners in Scotland. Almost all the great joint stock banks have numerous branches; so that there is hardly a town or village of any consequence without two or more banks.

The Bank of Scotland began to issue one-pound notes as early as 1704, and their issue has since been continued without interruption. With only one exception, all the Scotch banks issue notes; and taking their aggregate circulation at from 3,500,000*l.* to 4,000,000*l.*, it is supposed that from 2,000,000*l.* to 2,500,000*l.* consists of notes for 1*l.* In 1826 it was proposed to suppress one-pound notes in Scotland as well as in England; but the measure having been strongly objected to by the people of Scotland, as being at once oppressive and unnecessary, was abandoned.

There have been very few bankruptcies amongst the Scotch banks. This superior stability is to be ascribed to a variety of causes; partly to the great wealth of the early established banks, which had a considerable influence in preventing an inferior class of banks acquiring any hold on the public confidence; partly to the comparatively little risk attending the business of banking in Scotland; partly to the facilities afforded by the Scotch law for attaching a debtor's property, whether it consist of land or moveables; and partly and principally, perhaps, to the fact of the Scotch banks being but indirectly and slightly affected by a depression of the exchange and an efflux of bullion.

The circumstances now mentioned render it unnecessary to enforce that suppression of local issues in Scotland which is so indispensable in England, where the system of provincial banking is of a very inferior description, the risk attending the business much greater, and where any excess in the amount of the currency necessarily occasions a fall of the exchange and a demand for bullion. The commerce and population of Scotland are too limited, and that country is too remote from the metropolis, or from the centre of the moneyed world, the pivot on which the exchanges turn, to make it of importance that her currency should be identical with that of England. We believe that the Scotch attach much more importance than it deserves to the issue of paper, and especially to the issue of one-pound notes; still, however, we do not think that the circumstances are at present such as to call for or to warrant any attempt to introduce any material changes in their banking system.

All the Scotch banks receive deposits, even of the low amount of 10*l*., and allow interest on them at from one to two per cent. below the market rate. But should a deposit be unusually large, as from 5,000*l*. to 10,000*l*., a special agreement is usually made with regard to it. This part of the system has been particularly advantageous. It, in fact, renders the Scotch banks a sort of savings' banks for all classes; and their readily receiving all sorts of deposits at a reasonable rate of interest, has tended to diffuse a spirit of economy and parsimony among the people that would not otherwise have existed. The total deposits in the hands of the Scotch banks are believed at present (1838) to exceed 25,000,000*l*., of which fully a half is understood to be in sums of from 10*l*. to 200*l*.

The Scotch banks make advances in the way of discounts and loans, and on what are called cash-credits or cash-accounts. By the latter are meant credits given by the banks for specified sums to individuals, each of whom gives a bond for the sum in his account, with two or more individuals as sureties for its payment. Persons having such accounts draw upon them for whatever sums within their amount they have occasion for, repaying these advances as they find opportunity, but generally within short periods. Interest is charged only on the average balance which may be found due to the bank. The total number of these accounts in Scotland in 1826 was estimated at about 12,000; and it may now, perhaps, be taken at about 14,000. They are believed to average about 500*l*.; few are for less than 100*l*., and fewer still above 5,000*l*.

It has been contended by no less an authority than Adam Smith, that this species of accommodation gives the Scotch merchants and traders a double command of capital. "They may discount their bills of exchange," says he, "as easily as the English merchants, and have, besides, the additional conveniency of their cash accounts." But this is an obvious error. The circulation will take off only a certain quantity of paper; and to whatever extent it may be issued by means of cash-accounts, so much the less can be issued in the way of discounts. The advantage of a cash account does not really consist in its enabling a banker to enlarge his advances to his customers, but in the extreme facility it affords of making them. An individual who has obtained such an account may operate upon it at any time he pleases, and by drafts for any amount; an advantage he could not enjoy to any thing like the same extent, without an infinite deal of trouble and expense, were the loans and advances made to him through the discounting of bills. The Scotch banks draw upon London at twenty days' date. This is denominated the par of exchange between London and Edinburgh.

Irish Banks.—The Bank of Ireland was established in 1783, and the same restriction as to the number of partners in other banks that formerly prevailed in England was enacted in its favour. Owing to that and other causes the bankruptcies of private banks have been more frequent in Ireland than in England. In 1821 this restriction was repealed, as respects all parts of the country more than 50 Irish miles from Dublin. Since that period several banking companies, with large bodies of partners, have been set on foot in different parts of the country: of these the Provincial Bank, founded on the Scotch model, is among the most flourishing. The charter of the Bank of Ireland expired in 1838; but it will continue to go on till it receive notice to that effect. The Irish as well as the Scotch banks issue notes for 1*l*.

For accounts as to Foreign Banks, see the art. "Paper Money and Banks," in the new ed. of the *Encyclopedia Brittanica*, and the authorities there referred to.

BANK FOR SAVINGS. A bank established for the receipt of small sums deposited by the poorer class of persons, and for their accumulation at compound interest.

Though not so well calculated as friendly societies to enable the labouring classes to provide against sickness and old age, savings' banks are very valuable institutions, and are eminently entitled to the public patronage and support. The want of a safe place of deposit for their savings, where they would yield them a reasonable interest, and whence they could withdraw them at pleasure, has formed one of the most serious obstacles to the formation of a habit of accumulation among labourers. Public banks do not generally receive a less deposit than 10*l*.; and there are but very few amongst the labouring classes who find themselves suddenly masters of so large a sum; while, to accumulate so much by the weekly or monthly saving of a few shillings, appears at first view almost a hopeless task; and should an individual have the resolution to attempt it, the temptation to break in upon his little stock at every call of necessity might be too strong to resist. At all events, the progressive addition of interest is lost during the period of accumulation; and it even frequently happens that the chest of the servant or labourer is not safe from the depredations of the dishonest; while the very feeling of insecurity which such a circumstance inspires must operate as a fatal check to habits of saving. A similar effect results from the instances that have often occurred, where those poor persons who had, in despite of every discouragement, accumulated a little capital, have been tempted, by the offer of a high rate of interest, to lend it to persons of doubtful characters and desperate fortunes, whose bankruptcy has involved them in irremediable ruin. It is plain, therefore, that nothing could be more advantageous with a view to the formation of those improved habits that must necessarily result from the diffusion of a spirit of frugality and forethought among the poor, than the institution of savings' banks, or places of safe, convenient, and advantageous deposit for their smallest savings. They are no longer tempted, from the want of facility of investment, to waste what little they can save from their expenditure in frivolous or idle gratifications. They now feel assured that their savings, and the interest accumulated upon them, will be faithfully preserved to meet their future wants; and as there are very few who are insensible of the blessings of independence, there is no reason to suppose that they will be slow to avail themselves of the means of accumulation now in their power.

All moneys paid into any savings' bank established according to the provisions of the act 9 Geo. 4. c. 92., are ordered to be paid into the banks of England and Ireland, and vested in bank annuities or exchequer bills. The interest payable to depositors is not to exceed 2¼*d*. per cent. per diem., or 3*l*. 8*s*. 5¼*d*. per cent. per annum. No depositor can contribute more than 30*l*., exclusive of compound interest, to a savings' bank in any one year; and the total deposits to be received from any one individual are not to exceed 150*l*.; and whenever the deposits, and compound interest accruing upon them, standing in the name of any one individual, shall amount to 200*l*., no farther interest shall be paid upon such deposit. The number of depositors in savings' banks, in England, Wales, and Ireland, on the 20th of November, 1834, amounted to 499,207, and the deposits to 15,369,844*l*. giving an average deposit of 30*l*. 16*s*. to each. As far as we are aware, no return of the Scotch savings' banks has been published.

BA'NKRUPTCY, in Law, is a peculiar condition, with reference to legal liabilities and disabilities, into which certain classes of persons only are liable to fall. The word is said to be of Italian origin, and derived from the ceremony usual in some towns in the middle ages of breaking the bench or counter (bancus) occupied in the public exchange by the merchant.

The statutes respecting bankruptcy begin at the 34 H. 8., and end with those of the 6 G. 4. and 1 W. 4., in which the principles of the law on this head are now contained.

All persons engaged in trade, if in other respects capable of making valid contracts, are liable to be made bankrupts. The proof of trading is, buying and selling with a view to profit by dealing generally with the public; and it is a question of fact for the decision of a jury, whether a party be a trader or no. Acts of bankruptcy are of two sorts. 1. Such as tend to defraud or delay creditors. Such as departing from the realm under suspicious circumstances; keeping house; making a fraudulent conveyance, gift, or delivery of goods and chattels (in which all conveyances without a consideration, or voluntary conveyances, are included, and also conveyances or gifts to creditors with a fraudulent preference). 2. Such as are evidence of insolvency: as, for instance, a declaration of insolvency in the Gazette, a petition of insolvency in the Insolvent Debtors' Court, lying in prison twenty-one days after being arrested for a *bonâ fide* debt, or compounding under certain circumstances with a petitioning creditor. An assignment of the whole of a trader's effects for the benefit of his creditors is also an act of bankruptcy, on which a commission may be supported either immediately, or, under certain circumstances, within six months after such assignment has been made. An act of bankruptcy, concerted between a trader and his creditor with fraudulent views, is a contempt of court, and also an indictable offence.

When an act of bankruptcy has been committed by a trader, a commission, or, as it is now termed, a *fiat* in the nature of a commission, may be sued out (with certain exceptions) immediately, by a creditor or creditors to a stated amount: such creditor is then termed a petitioning creditor. The bankruptcy will then be held to have commenced at the time when the act of bankruptcy on which the petition is supported was committed. The striking what is termed a docket in the bankrupt office gives priority of petitioning to a creditor. The fiat when issued is opened, and the circumstances necessary to constitute a bankruptcy proved before a commissioner of bankrupts. There are six commissioners, nominated according to the act of the 1st year of W. 4.; and of these three together form a subdivision court for the purpose of acting in concert on questions of difficulty. The assignees of the estate and effects of the bankrupt are then chosen by the creditors among themselves; and to these, in conjunction with an official assignee appointed

by the court, the whole property of the bankrupt is assigned by adjudication. From the decision of a commissioner or subdivision court there is an appeal to the court of review in bankruptcy, instituted by the same act; and from thence to the lord chancellor, and finally to the House of Lords. The jurisdiction in bankruptcy is both legal and equitable.

By the assignment, the whole property, real and personal, of the bankrupt, is vested in the assignees from the period of the act of bankruptcy, to the avoidance of all the bankrupt's subsequent transactions, except such as have been performed *bonâ fide* with parties having no notice of such act; the notice being understood according to ordinary rules in equity. Besides the bankrupt's own property, such property of third parties as shall have been in his use and disposition, or reputed ownership, by permission of the true owner, passes to his assignees. The bankrupt's right of action of contract, and of tort to property, but not personal torts, pass likewise to his assignees. But actions against him, except for the recovery of specific real property, do not lie against the assignees, the amount claimed being proveable as a debt under the commission; unless in some cases, where the right of action has accrued subsequently to the appointment of the assignees. The debts which may be proved by creditors against the bankrupt's estate are either certain or uncertain in their amount: the first class including such as are either specific sums of money lent or due, or such as are originally uncertain, but capable of being liquidated or reduced to a certain amount; the second, such as can only be estimated on general principles of equity. It is the business of the assignees to collect the estate of the bankrupt, as ascertained by his examination upon oath and by inspection of his books; but monies on account of the bankrupt's estate are received by the official assignee alone, and paid by him into the Bank of England in the name of the accountant-general of the Court of Chancery.

Not sooner than four months, nor later than twelve after the issuing of the fiat (unless ordered by the court of review), a public meeting of creditors is appointed for the purpose of making the first dividend of the net estate after certain necessary liabilities have been provided for out of it. A second dividend, if necessary, is made within eighteen months of the issuing of the fiat; after which a third or more may follow, according to circumstances. A bankrupt refusing to surrender his estate, or to make full discovery respecting it, is liable to transportation for life. While the proceedings are going on, he is entitled to maintenance out of his estate. The certificate of conformity is a testimony given to the bankrupt of his having, since his bankruptcy, complied with the requisitions of the law: it cannot, however, be obtained without the consent of a certain proportion of the creditors; and it is open for any creditor certain of misconduct on the part of the bankrupt, subsequent or even previous to the bankruptcy, to oppose the granting of this certificate. The effect of the certificate, besides entitling the bankrupt to an allowance, where a dividend of 10*s.* in the pound or upwards has been paid to the creditors (being a percentage on his estate, limited, according to circumstances, so as not to exceed in any case 600*l.* per annum), is to discharge his person and future estate from all claims and debts which might have been proved under the bankruptcy. But in case of a second bankruptcy, or a bankruptcy after discharge under the Insolvent Act or composition with creditors, unless 15*s.* in the pound has been paid, the effect of the certificate is only to discharge the person.

BA'NKSIA. (In honour of Sir Joseph Banks, Bart., the great patron of natural history, and one of the companions of Captain Cook in his second voyage.) A genus of Proteaceous plants forming a conspicuous feature in the landscape of Australia, where the species are called by the colonists wild honeysuckle, and reckoned a sign of bad land. They have flowers and fruit growing in close hard downy or woolly cones, and hard broad leaves on branches so close and rigid that the traveller, it is said, may literally walk without inconvenience upon the top of a wood formed of these trees.

BA'NLIEUE. (Fr.) The territory without the walls, but comprised within the legal limits of a city or town. The word is evidently derived from Ban (bannus, &c.), but the immediate origin is unknown.

BANN. A proclamation commanding or forbidding any thing. Hence the public notices of marriage given in church, derived from the civil law, are called Banns of Marriage. According to the law of England, the banns must be published three successive Sundays; and if the marriage be not performed within three months from the last publication, the same process must be repeated. Bishops have the power of appointing surrogates, who may grant a faculty or licence to parties applying to be married without banns. But this licence may only be given under certain conditions, and upon good caution and security taken, such as to supersede the necessity of public proclamation.

BA'NNER. (Swed. baner; Fr. banniere.) A flag or standard under which men are united or bound for some common purpose. This word, found in all the modern languages of Western Europe, is of very doubtful origin; it is a word of which our ancient English authors were exceedingly fond, and to which they invariably attach the same meaning. (Chaucer, *the Knight's Tale*, v. 978.; *Sir Thomas More's Works*, 207.; Drayton, *Battle of Agincourt; Yalden to Sir H. Mackworth*, &c.) Among the ancient Germans, the honour of bearing a banner was conferred by the emperor on that individual who could bring ten vassals into the field. In later times, petty princes assumed this privilege; and in the year 1424 Pope Eugene IV. created Count Sforza banneret (bannerherrn) of the Roman empire. In the free towns on the Continent, the banner was always carried by the chief magistrate ex officio, in cases of solemnities or of grand processions. In England, a knight banneret was created by the ceremony of cutting off the four corners of his standard and making it square. Some antiquarians trace the origin of this custom to Conan, the lieutenant of Maximus, who governed Britain in the year 383 (Gwillim, *Analogia Honorum*); while others maintain it took its rise from the Black Prince on the field of Cressy. A wonderful similarity seems to exist between the duties and privileges of the old knights bannerets of England and those of the primipili (the standard bearers) among the Romans. (*Tac. Histor.* iii. 22.) Several banners are famous in history; such as the Danish banner, taken from the Danes by Alfred the Great; and the oriflamme of the French, which, after passing through various hands, became eventually the great standard of France. (Lanzelot, *Memoires de l'Academie des Inscriptions.*)

BANNER. The ordnance flag, fixed on the forepart of the drum-major's kettle-drum carriage, formerly used by the royal artillery. At present, when such a flag is carried it is affixed to the carriage of the right-hand gun of the park — generally a twelve-pounder.

In the horse equipage the *banner* of the drums and trumpets must be of the colour of the facings of the regiment: it bears the royal cypher and crown, and the rank of the regiment.

BA'NNERET. A knight who in the feudal times possessed a certain amount of fiefs, and had the right of carrying a "banner." This honour was also very generally adopted among European nations, and was awarded on the field of battle to such as had there distinguished themselves. Knights bannerets were considered, in England, next to barons in precedence. The dignity has not been conferred for a long period. The banner of a banneret was oblong, that of a baron square. When a knight bachelor was made banneret on the field of battle, the ceremony was performed by cutting off the ends or tails of his pennon, and thus converting it into a banner. *See* KNIGHT.

BA'NYAN. A kind of Indian fig, the *Ficus indica* of Linnæus, forming a very large tree, which sends down roots from its branches, and those roots striking into the ground themselves become trunks, which serve as props to the extending branches; and as the tree is very long-lived, the quantity of ground an individual will thus cover is incredible. Dr. Roxburgh says, he has seen the tree 100 feet high, and full 500 yards in circumference round the extremities of the branches. It is found wild in the skirts of the Circar mountains; its leaves are used by the Brahmins as plates to eat off; a species of birdlime is obtained from its juice, and the fruit is eaten by birds.

BA'OBAB. The African name of *Adansonia digitata*, a tree inhabiting the western side of Africa, and cultivated in Egypt and Abyssinia. It increases more in proportion in diameter than in height; so that it may be seen with a trunk 10 yards in thickness and only 73 feet high, its appearance being lumpish and inelegant. It is supposed that the most remarkable cases of longevity in the vegetable kingdom are afforded by this tree. Adanson is quoted by De Candolle as asserting that he saw individuals which must have been 6000 years old; and other travellers declare that however ancient the individuals may be, the bark is always green and shining, and so full of life that an abundant discharge takes place at the least wound. It is probable that the data upon which these calculations are made will not bear strict investigation; nevertheless, there can be no reasonable doubt of the Baobab trees arriving at a most unusual age. The leaves are employed in powder as an ingredient in African cookery; and the fruit has a sub-acid juice, which makes it valuable in fevers.

BA'PHOMET. The imaginary idol, or rather symbol, which the Templars were accused of employing in their mysterious rites. (*See* TEMPLARS.) The distinguished orientalist Hammer has published a dissertation on this subject, in which he endeavours to revive the ancient accusations against that military order. These images, which he calls Baphomet, are to be found in some of the museums of continental cities; they are small human figures with two heads, and covered with emblems, to which Hammer attaches a very horrible signifi-

cation. He derives the name (very improbably) from the Greek words βαφη, dipping or baptism, and μητις, counsel or wisdom: as if they represented the admission of the initiated to the secret mysteries of the sect. It is proper to observe, that other writers have treated all this discovery as a mere fancy of the learned orientalist, and maintain that the figures which he terms Baphomets are in reality relics of the art magic: while the word itself is supposed to be a corruption (arising from the negligence of some transcriber) of the name Mahomet, occurring in the depositions of witnesses against those unfortunate knights.

BA'PTISM. (Gr. βάπτω, *I dip.*) The rite of initiation into the community of Christians, ordained by Christ himself, when he commissioned his apostles to go and baptize all nations in the name of the Father, the Son, and the Holy Ghost.

It is recorded by the Evangelists, that our Saviour himself received baptism from John; and the ceremony which the Baptist performed is allowed generally to have been an imitation of a rite in common practice among the Jews, who appear to have admitted proselytes by circumcision and baptism. Lustration, however, by water, as an initiatory rite, is of great antiquity and general practice, especially in the East; and Christian baptism may be considered as an adaptation of a form which was generally understood to have a symbolical meaning. Accordingly, it has been recognised by all Christian communities as a sacrament, although they have differed in their explanation of its nature and meaning. It is upon this point that the question of the validity of infant baptism principally depends; the words of Scripture in that particular not being allowed on all hands to be decisive, nor even the practice of the early church universally admitted. Those, therefore, who consider baptism to be a symbol of a covenant thereupon entered into between God and the person baptized, require the understanding of the person to accompany the act, and reject the notion of sponsors undertaking to promise on the part of infants: the more common notion, however, conceives this sacrament to have in itself a regenerative virtue, by which an infant may be received into participation in the promises made to the church, and be really and truly from that time forth put into the way of salvation.

Baptism was originally administered by immersion, which act is thought by some to be necessary to the sacrament. It is not clear, however, even in the Scripture history, that this ceremony was always adhered to. At present sprinkling is generally substituted for dipping, at least in northern climates.

BA'PTISTERY. (Gr. βαπτιζω, *I baptize.*) In Architecture, a building destined for the purpose of administering the rite of baptism. Some authors have contended that the baptistery was anciently placed in the interior vestibules of the early churches, as are in our days baptismal fonts. But this is not so: the baptistery was entirely separated from the basilica, and even placed at some distance from it. Up to the end of the sixth century, after which period the interior vestibule of the church received it, the baptistery was distinct from the church; and excepting in a few churches, such as that at Florence, and those of all the episcopal cities of Tuscany, Ravenna, and San Giovanni Laterano, and perhaps of a few other places. the practice was general. The last mentioned is perhaps the most ancient remaining. One at Constantinople was so large that on one occasion it held a very numerous council. The baptistery of Florence is nearly 90 feet in diameter, octagonal, and covered with a dome. The celebrated bronze gates by Lorenzo Ghiberi, which Buonarroti said were fit to be the gates of Paradise, enclose it. The baptistery at Pisa, designed by Diotisalvi, was finished about 1160. It is octagonal, about 129 feet in diameter, and 179 feet high. We are not aware of any building of this sort having been erected in England.

BA'PTISTS. A denomination of Christians, who deny the validity of infant baptism, and maintain the necessity of immersion. These were also the principal tenets of the Anabaptists, or Rebaptizers, with whom, however, the modern Baptists ought not to be confounded. They are subdivided into two classes, the Particular (Calvinist) and the General (Arminian) Baptists. The mode of church government is similar with both, acknowledging three orders of ministers; of whom the messengers correspond to bishops, the elders to priests, and ministering brethren to deacons. Their churches are congregational, and in respect to the election of their own ministers independent. Each denomination has, however, its general assembly, possessing some kind of authority over the whole community. The Baptists are numerous in Holland, where they are known by the title of Mennonites; and in England they form one of the principal Dissenting bodies.

BAR. A shoal often found lying across the mouth of rivers, and also of harbours; thence called bar harbours. As the sea breaks on these places, in bad weather the passage of a bar is generally dangerous.

BAR, CONFEDERATION OF. In Politics, was an association of a few influential Polish nobles, formed at Bar, a small town of Podolia, in the year 1767, for the purpose of freeing their country from foreign influence. Their efforts, however, were eminently unsucccessful: the small bands of the patriots were annihilated one by one; and their defeat gave rise to an event almost unprecedented in history, — the partitien of Poland by the three neighbouring powers.

BAR. The bar or place in the courts of law where barristers or advocates plead: also where prisoners accused of felony are stationed for arraignment and trial.

BAR. In Heraldry, a kind of ordinary, resembling the *fess*, but containing only the fifth part of the field. Where two bars are borne in an escutcheon, they are so arranged that the whole field appears divided into five parts. A field divided by horizontal lines into four, six, eight, ten, or twelve equal parts, with alternate tinctures, is termed *barry* of four, six, eight, &c.

BAR. (Sax. Beorgan, *to bar.*) In Music, a line drawn vertically across the lines of the staff, including a certain quantity or measure of time, varying as the music is either triple or common.

BAR, ELOQUENCE OF. *See* ELOQUENCE.

BA'RBA. (Lat. barba, *a beard.*) In Mammalogy, signifies the long tuft of hair dependent from the under jaw. In Ornithology, the same term is applied to the setiform or simple feathers, which in some species of birds depend from the skin covering the gullet or crop. In Ichthyology, a kind of spine, with the teeth pointing backwards.

BARBA. A beard; a term used in Botany to denote any collection of long loose hairs into a tuft or crest, as on the petals of the iris.

BARBA'DOES LEG. A disease indigenous to Barbadoes, in which the limb becomes tumid, hard, and misshapen.

BA'RBARISM. (Gr.) In Rhetoric, an offence against purity of style or language, which consists in employing uncouth or antiquated expressions, or in assigning to terms a different signification from that which usage has conferred on them.

BA'RBASTELLE. A small indigenous bat; *Plecotus barbastellus*, Lisson.

BA'RBEL. An indigenous fresh-water fish (*Cyprinus barbus*, Linn.) which takes its name from the processes termed Barbels.

BA'RBELLATE. (Lat. barba.) When the pappus of composite plants is bearded by short, stiff, straight bristles, as in Centaurea. Barbellulate is used when the roughness of the pappus is caused by extremely short points, as in Aster.

BA'RBELS. Small cylindrical vermiform processes appended to the mouth of certain fishes, and subservient to the sense of touch.

BA'RBER. (Lat. barba.) A person who makes a trade of shaving and dressing the hair of other people for money. It would seem that it is only where a state has made considerable progress in civilisation that this art begins to flourish. If we believe Varro, for instance (*Plin.* 7. 56.), it was not until the 454th year of the city that Ticinius Mena first imported barbers into Rome from Sicily. Their shops (Tonstrinæ) soon became the resort of fashionable loungers and idlers; and Horace, to indicate the extreme notoriety of a story, says that it was "omnibus et lippis notum et tonsoribus." Even the poorest citizens, according to the same author, sought refuge from their ennui in making a round of the barbers' shops:—

> Mutat cœnacula, lectos,
> Balnea, tonsores.

That the Romans paid great attention to this department of the toilet, is obvious from the ridicule that was excited against any citizen whose hair bore marks of being cut "inæquali tonsore" (by a bungling barber).

But besides shaving the beard, to the barbers of the Romans was assigned the delicate task of trimming the nails. Hence Plautus, *Aulul.* ii. 4. 33.—"Quin ipsi pridem tonsor ungues dempserat;" and Tibullus, I. 9. 11. —

> Quid ungues
> Artificis doctâ subsecuisse manu.

As early as the time of Hippocrates, some surgical operations were considered as degrading to physicians, and consequently fell to be performed by barbers. In France the council of Tours, in the year 1163, prohibited the clergy, who then shared with the Jews the practice of medicine in Christian Europe, from performing any bloody operation; and from that time the barbers remained for some centuries in uninterrupted possession of the practice of surgery. In England also, early in the 16th century, the barbers were incorporated with the surgeons of London (32 Hen. 8. c. 42.); but at the commencement of last century, when a new impulse was given to the science of surgery by the attainments and ability of many practitioners throughout Europe, the

barbers were degraded from their honourable association with surgeons. (18 Geo. 2. c. 15.) In Holland and Germany to this day the barbers are wont to wield the lancet and the razor alternately. Nowhere, however, in these countries is the business of haircutting carried on by the barbers, but by a distinct and superior class, the friseurs. The barber's pole has given rise to many speculations and ingenious absurdities. The fact is, that the pole was the distinguishing characteristic of a few only, being a mark of superior skill, and indicated on the part of him who possessed it surgical as well as tonsorial ability. (For some curious remarks on the barbers of Edinburgh, vide *Creech's Statistical Account of Edinburgh.*)

BA'RBERRY. *See* BERBERRY.

BA'RBICAN. A watch tower for the purpose of descrying the enemy: also the outer work or defence of a castle, or the fort at the entrance of a bridge. Apertures in the walls of a fortress for firing through upon the enemy are also called barbicans. Authors have ascribed to this word a French, Italian, Spanish, Saxon, and Arabic origin.

BA'RBITON. An ancient musical instrument, somewhat resembling the lyre.

BAR'BULA. (Lat. barba, *a beard.*) A finely divided beard-like apex to the peristome of some mosses, as in the genus Tortula.

BA'RCAROLLE. A song sung by the Venetian gondoliers. A boat song (from the Italian *barcarola*).

BARDS. The ancient poets of the Celtic tribes are so termed by the Roman writers. The etymology of the word is uncertain. According to the ancients, they appear to have been the priests as well as the instructors of these tribes, and regarded with peculiar veneration. Lucan expressly mentions the doctrine of the immortality of the soul as one of their most characteristic tenets. After the introduction of Christianity the importance of the bards in society diminished; but in Wales, Ireland, and other Celtic districts, they continued to be held in much honour. The most ancient compositions of Welsh bards which we possess (those of Taliessin, Aneurin, and Lywarch) are supposed to be of the sixth century.

BARE POLES. The masts without any sails upon them, the ship being at sea. Under bare poles, in general, implies that the wind is so high that no sail can be exposed to it.

BA'RGAIN. *See* CONTRACT.

BARGE. (Gr. *βάρις, a kind of ship.*) A general name given to flat-bottomed craft of a certain size employed on rivers and canals. Also one of the larger boats of a man of war, between 30 and 40 feet long. Barge is also a general term for boats of state or pleasure.

BARGE BOARDS. (Sax. pÿpgan, *to bar.*) In Architecture, the inclined projecting boards placed at the gable of a building, which hide the ends of the horizontal timbers of a roof, and are frequently carved with trefoils, quatrefoils, flowers, and other ornaments.

BARGE COURSE. In Architecture, that part of the tiling of a roof which projects beyond the external face of the gable of a building.

BARI'LLA. The name given in commerce to the impure carbonate of soda, imported from Spain and the Levant. It is made by burning certain plants that grow upon the sea shore, especially the salsola soda, to ashes, which are fused into grey porous masses. (For an account of the places where it is produced, the quantities shipped from them, and the uses to which it is applied, see *M'Culloch's Commercial Dictionary.*)

BA'RITONE. (Gr. *βαρυς, heavy,* and *τονος, a tone.*) In Music, a high bass, which, in the ancient church music, is written with the F clef on the third line of the staff. By the French it is called basse-taille.

BA'RIUM. The metallic base of baryta; it is of a grey colour, more than twice as heavy as water, and is instantly oxidized by air and by water.

BARK. (Ger. bergen, *to cover.*) The exterior covering of the trunk of a tree. It is composed of cellular tissue, traversed by woody tissue passing down it longitudinally, and connected with the medullary processes of the wood. It is increased in trees by annual layers formed on its inner face, and gradually perishes on the outside as it is distended by the growth of the interior. It seldom, however, shows any very distinct trace of concentric circles, because the latter are continually displaced and disturbed by its distention. Its inner face is named liber. At the commencement of the annual growth of a tree, it separates spontaneously from the wood, in order to make room for the new matter forming beneath it. It is the depositary of many of the secretions of plants, and seems to act as a living filter of a curious kind, separating certain secretions from others, and allowing a part only to pass off horizontally in the medullary processes on their way to the centre of the tree. Its use is to act as a protector to the wood, and as the channel of the sap in its descent from the leaves. Its fibre is often tenacious, and manufactured into linen or cordage. True bark only exists in Exogens and Gymnosperms; in Endogens its place is supplied by a cortical integument, which cannot be separated from the subjacent wood without violence.

BARK, PERUVIAN. *See* CINCHONA.

BARK. Originally a general term for a vessel, is now restricted to a particular form of rig; namely, that of a ship, but having a gaff topsail instead of the square mizen topsail.

BARK, USE OF IN TANNING. *See* TANNING.

BA'RKING IRONS. Instruments for removing the bark of oak and other trees which is used for tanning. They consist of a blade or knife for cutting the bark, while yet on the trunk, across at regular distances, and of chisels or spatulæ, of different lengths and breadths, for separating the bark from the wood.

BARK STOVE. A glazed structure for tropical plants, in which there is a bed of tanner's bark, or of some other fermentable material, which will produce a moist heat.

BA'RLEY. (Hordeum, *L.*; Triandria monogynia, *L.*; Gramineæ, *Juss.*; characterised by an imbricated-spiked inflorescence, consisting of one-flowered spikelets in twos or threes.) A bread corn of considerable importance. Its native country is unknown, some ascribing it to Tartary, others to Siberia, and a few to Scotland. In Spain and Sicily it produces two crops in the year; but in countries as far north as Britain it produces only one, and is rather a delicate species of grain. In England it is second in importance to wheat. It is a most valuable crop in the rotation best adapted to light or turnip soils, which, from that circumstance, are sometimes called barley lands. Where its culture is best understood, as in Norfolk, it is generally preceded by turnips or other green crop. There are two leading species of this grain in cultivation, — the *Hordeum distichon*, two-rowed or common barley; and the *Hordeum hexastichon*, or six-rowed barley. One of the best known varieties of the latter, and the only one in common cultivation in Scotland, is called bear or bigg. It is not now very extensively used as a bread corn; but it is used very extensively in malting, and in the fatting of black cattle, hogs, and poultry. The crops differ very widely, according to the land and the season, varying from 28 to 64 bushels an acre; but the most usual crop is from 28 to 40 bushels. The common weight of barley is 50 or 51 lbs. per Winchester bushel; but the best Norfolk barley weighs 53 or 54 lbs. The price of barley in 1837 was **30*s.* 4*d.*** a quarter.

BA'RNACLES. *See* CIRRIPEDS.

BARO'METER. (Gr. *βαρος, weight,* and *μετρον, measure.*) A well-known instrument for measuring the weight or pressure of the atmosphere. The invention of the barometer was in some degree owing to an accident. Some workmen employed by the Duke of Florence to prepare a sucking-pump for a deep well, found to their surprise that notwithstanding their utmost care in forming and fitting the valves and piston, the water would not rise higher than 18 palms, or about 32 English feet. For an explanation of this unexpected difficulty they applied to the illustrious Galileo, then passing the evening of his life at his villa near Arcetri; but the philosopher was not yet prepared with the true answer. In that age the doctrine of a *plenum* was an axiom in philosophy; and the ascent of water in the barrel of the pump was universally ascribed to nature's horror of *a vacuum*. Galileo, either fearing to encounter further persecutions by propounding opinions at variance with the prejudices of the times, or preoccupied by the prevailing metaphorical modes of expression, evaded the difficulty by saying that the power of nature to overcome a vacuum was limited, and did not exceed the pressure of a column of water 32 feet in height. That he was himself little satisfied with this explanation. is evident from the circumstance that previously to his death, which happened soon after, in 1642, he earnestly recommended to his pupil Torricelli to undertake the investigation of the subject, which the infirmities of advanced age no longer permitted him to prosecute. Torricelli, suspecting the true cause of the suspension of the water, namely, the weight of the atmosphere, happily conceived the idea of trying the experiment with mercury. He perceived that if the weight of the atmosphere forms a counterpoise to a column of water of 32 feet, it must also counterpoise a column of mercury of about 28 inches in height, the weight of mercury being about 14 times greater than that of water. Having accordingly procured a glass tube of about 3 feet in length and a quarter of an inch in diameter, hermetically sealed at one end, he filled it with mercury; and covering the open end with the finger, he immerged it in an open vessel containing mercury. On bringing the tube to the vertical position, and removing the finger, the mercury instantly sunk, leaving a vacuum at the top of the tube, and, after making several oscillations, stood in the tube at the height of about 28 inches above the surface of that in the vessel. On covering the mercury in the vessel with a portion of water, and raising the tube till the lower end came into contact with the water, the mercury all ran out, and the water rushed up to the top of the tube. This experiment,

called after its author the *Torricellian experiment*, demonstrated that the mercury was sustained in the tube, and the water in the barrel of the pump, by exactly the same counterpoise, whatever the nature of it might be. Torricelli died shortly after, in the flower of his age, without completing his great discovery; but the fame of his experiment was soon carried into other countries, and the subject engaged the attention of the most eminent philosophers; among others the celebrated Pascal. After a variety of ingenious experiments on the subject, all of which tended to establish the pressure of the atmosphere, it at length occurred to Pascal that if the mercurial column was really supported by atmospheric pressure, it must be affected by the weight of the superincumbent mass of air, and consequently be diminished at considerable elevations. In order to verify this conjecture, he requested his brother-in-law, Perier, to try the experiment on the *Puy de Dome*, a lofty conical mountain in the province of Auvergne, which rises to the height of 500 toises. At the foot of the mountain Perier filled two tubes, and observed the mercury in each to stand at precisely the same height, nearly 28 English inches. Leaving one of them under the care of a person to watch its rise or fall, he carried the other to the top of the mountain; and on repeating the experiment there, the mercury stood at the height of only 24·7 English inches. At two intermediate stations in his descent, the mercury was observed successively to rise, and at the foot of the mountain it stood at exactly the same height in the tube as at first. This experiment was decisive; the result of it was communicated to Pascal at Paris, who, after confirming it by similar observations made successively on the ground, and at the top of a glass-house and the belfry of a church, proposed the barometer as an instrument for measuring the height of mountains, or the relative altitudes of places above the surface of the earth.

The barometer had been but a short time invented, before it was observed that the height of the mercurial column is subject to variations connected in some way with the changes of weather. But the variations are confined within a limited range, scarcely exceeding 3 inches in all, and often, for many days together, do not exceed a few hundredths of an inch. It therefore was considered desirable to render these minute oscillations more apparent by increasing their range; and accordingly, of the numerous forms which the barometer has received, or which have been suggested, the greater part have been proposed with a view to this purpose. The most remarkable or useful constructions are the following, the descriptions of which will be readily understood with the assistance of the diagrams:—

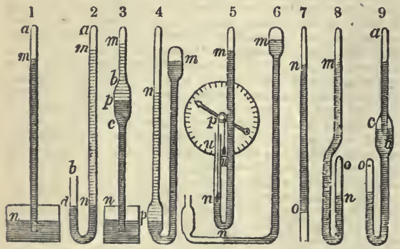

Fig. 1. is the *Cistern Barometer*, and is merely the inverted tube of Torricelli already described. The tube must be about 34 inches long. When placed in the cistern, the mercury sinks till the column between the two surfaces *m* and *n* just counterbalances the pressure of the air. The space above the mercury, *a m*, is or ought to be a perfect vacuum, or only filled with the vapour of mercury. In this barometer, as the diameter of the cistern is generally very much greater than that of the tube, almost the whole effect of the rise or fall is perceived in the variation of the upper surface at *m*. For supposing the section of the cistern 20 times greater than that of the tube, and that the height of the column *m n* suffers a diminution of one inch; it is evident that, as all the mercury which goes out of the tube passes into the cistern, when it falls at *m* it must rise at *n*, but less in proportion as the section of the cistern exceeds that of the tube. In the case supposed, therefore, the alteration of the level at *m* will be 20 times greater than at *n*; that is to say, there will be a fall of $\frac{20}{21}$ of an inch at *m*, and a rise of $\frac{1}{21}$ of an inch at *n*.

Fig. 2. is the *Siphon Barometer*, which was also proposed by Torricelli, as being more convenient than the former. It is merely a tube hermetically sealed at the upper end, having the lower or open end bent upwards in the form of a siphon. The variations in this are only half as great as in the cistern barometer; for the tube being of the same width throughout, a diminution of the column *m n* amounting to one inch will be marked by a fall of half an inch at *m* and a rise of half an inch at *n*. This inconvenience may, however, be remedied by having the lower branch blown into a wide bulb; but as it is very difficult to procure the bulb to be blown into a perfectly regular shape, this enlargement of the bulb is found to give rise to inaccuracies.

Fig. 3. is a barometer suggested by Descartes, and executed by Huygens, in which the sensibility is greatly increased. Two tubes are cemented to the opposite ends of a pretty wide cylinder, *b c*. The lower tube and a portion of the cylinder, *c p*, are filled with mercury; above which water or spirit of wine is introduced, reaching to the top of the upper tube, which is hermetically sealed. The vacuum is made, as in the Torricellian barometer, by inverting the compound tube in a basin of mercury. The enlargement of the scale obtained by this construction is found thus: Suppose the horizontal section of the cylinder, *b c*, to be 10 times that of the tube, and the specific gravity of mercury 14 times that of water. Let *x* be the fall of the mercury in the cylinder at *p*, corresponding to a fall of one inch of the common Torricellian barometer. The descent of the water *x* inches at *p* will be marked by a descent of 10 *x* inches in the tube at *m*. But the diminution of the height of the column of water must correspond to a diminution of $(1-x)$ inches in the height of the column of mercury of equal weight with the water; therefore, the diminution of the column of water is 14 $(1-x)$ inches. Hence $10\,x=14\ (1-x)$, or $x=\frac{7}{12}$, and the descent of the water at $m=\frac{70}{12}=5\frac{5}{6}$; that is to say, when the Torricellian barometer falls one inch, the barometer of Descartes falls $5\frac{5}{6}$ inches. The defect of this construction is, that the air contained in the water escapes into the vacuum above, and destroys the accuracy of the instrument.

Fig. 4. is a form proposed by Huygens, to obviate the defect of the former. The siphon barometer terminates in two equal cisterns, or enlarged tubes; that at the open end communicating with a narrow tube containing water. In this case we may neglect the weight of the water between *n* and *p*, or consider it as a small addition to the weight of the atmosphere; the variations at *n* will be then as much greater than in the common siphon barometer as the horizontal section of the cisterns exceeds that of the tube at *n*. Thus, suppose the section of the cistern 10 times that of the tube; a variation of atmospheric pressure causing a fall of one inch in the Torricellian barometer will cause the mercury at *p* in this barometer to rise half an inch, and the water at *n* to rise 10 times as much, or 5 inches. The defects of this barometer are these: first, as the water descends at *n*, a portion of it adheres to the sides of the tube, and consequently diminishes the length of the column; secondly, the volume of the fluid in the reservoir is considerably affected by the influence of heat and cold; and, thirdly, the instrument is subject to constant derangement from the evaporation of the water.

Fig. 5. is the *Wheel Barometer*, proposed by Hooke. A small weight floats on the surface of the mercury in a siphon barometer, which is very nearly counterpoised by another weight, *w*, connected with the former by a string passing over a pulley, *p*. When the mercury rises at *n*, the weight *w* descends, and turns the pulley. An index attached to the axle of the pulley shows on a dial the quantity of revolution. This barometer, though very commonly met with, is a mere toy; and indicates neither the absolute height of the mercurial column, nor its variations, with sufficient accuracy to be of the slightest use for any philosophical purpose whatever. Even as a weather glass, it is the worst of all the common forms of the barometer.

Sir Samuel Moreland proposed to enlarge the scale, by inclining the upper part of the tube so as to form a considerable angle with the perpendicular. By this contrivance the scale is increased in the proportion of radius to the cosine of the angle of inclination; but the friction on the sides of the tube is greatly increased, and it is very difficult to determine the exact plane of the top of the column which requires to be read off on a vertical scale. This construction is easily conceived without a diagram.

Fig. 6. is a form proposed by John Bernoulli. The tube terminates in a horizontal branch of considerable length and small diameter: the pressure of air on the column of mercury is exerted horizontally, and by making the vacuum in a cistern at the top, the range becomes very great; but the mercury moves along the horizontal branch with difficulty, and by starts. No reliance can be placed on its indications.

Fig. 7. represents an extremely elegant and ingenious form of the barometer proposed by Amintons. A conical tube about 4 feet long, closed at the top, is partly filled with mercury, and inverted. The diameter of the tube must be small, scarcely exceeding 3-20ths of an inch at

the wide end, and tapering away to about 1-10th near the top. The pressure of the atmosphere from beneath prevents the mercury from falling out, but it descends in the tube till it comes into such a position that the height of the vertical column forms an exact counterpoise to the atmospheric pressure. If the pressure is diminished, the mercury sinks a little at *n*; but as it there fills a tube of larger diameter, its vertical height undergoes a corresponding diminution. The height of the upper surface at *m* therefore marks the absolute height of the vertical column, supposing the tube to taper equally; but the difficulty, or rather the impossibility, of fulfilling this condition practically, prevents this kind of barometer from being used.

We shall notice only one or two other forms of the barometer, proposed with a different view from that of enlarging the scale. Fig. 8. is a modification of the siphon barometer proposed by Gay Lussac. It differs from the common form in this respect, that, after the tube has been filled, the short branch is hermetically closed at the top, and the communication with the atmosphere takes place through a small capillary hole drilled laterally through the tube at *o*, so fine that though it admits the air to pass freely, it prevents the passage of the mercury. The barometer is thus rendered very convenient for carriage; but notwithstanding the promising appearance of this barometer, it has been found, particularly in travelling, that a portion of air will frequently insinuate itself through the mercury. In order to prevent the possibility of this accident, an ingenious modification has been made by M. Bunten, a Parisian artist. It consists in causing the part of the tube *a b* to terminate in a very fine point, and to penetrate to some depth into the other part *c o*, to which it is joined at *c*, in the manner represented in fig. 9. Now if an air bubble from the end *o*, which communicates with the atmosphere, should find its way through the bent capillary tube, it will pass along the sides of the bulging part, and instead of penetrating to the vacuum at *a*, will be arrested at *c*, whence it is easily expelled by reversing the barometer.

None of the contrivances which have been described for increasing the range of the oscillations have been found to succeed well in practice. It is found to be decidedly better to apply minute divisions, than to attempt to enlarge the scale; accordingly, experimenters now adhere to one or other of the two ancient forms, the cistern barometer and the siphon barometer. The height of the column in the siphon barometer is conveniently measured by means of a moveable scale attached to the frame which supports the tube; by means of a tangent screw, the scale is raised or lowered till its zero coincides exactly with the surface of the mercury in the lower branch; and with the assistance of a vernier, the height can be read off to the hundredth or two-hundredth of an inch with sufficient precision. The scale of the cistern barometer is usually fixed, and the bottom of the cistern is raised or lowered by a screw till the surface of the mercury in it coincides with the zero of the scale; but the scale may be moveable, and its zero brought to coincide with the surface of the mercury in the basin, as in the former case. In order to determine when this coincidence takes place, various expedients may be had recourse to. The most usual is to place on the surface of the mercury a float carrying a vertical needle, some point on which answers to a fixed point on the scale, and the coincidence obtains when the two points are brought into the same level. Another contrivance to effect the same purpose was employed by Fortin, a celebrated French artist. An ivory needle is attached to the scale, pointing downwards, and having its point exactly in the same level with the zero of the scale. The image of the needle is clearly reflected from the surface of the mercury in the cistern, and the cistern is raised or lowered till the point of the needle and its image precisely coincide.

In order to construct a good barometer, it is indispensably necessary that the mercury be perfectly free from impurities, and carefully purged of air; this is obtained by boiling it. The particles of air and moisture which cling obstinately to the sides of the tube must also be expelled by heat; the mercury must then be introduced slowly and continuously in a hot state, and while the tube continues hot. Since the time of Deluc it has been usual to boil the mercury in the tube before inverting it and forming the vacuum; but doubts now begin to be entertained among the most skilful makers of the expediency of this very troublesome process. The mercury is partially oxydated by boiling, and a thin crust formed, which keeps the column suspended at a greater height, and obstructs the freedom of the motion. It is important that the diameter of the tube be not very small; for it is found that the mercury moves with more freedom in a tube of considerable width, the oscillations following the atmospheric changes with more promptitude than in one of smaller dimensions; besides which, there is less disturbance from capillary attraction. The interior diameter should in every case exceed one fourth of an inch.

The value of the barometer as a scientific instrument depends on the purity of the mercury, and the total exclusion of atmospheric air. By proper care in the construction, it is, perhaps, possible to expel every particle of air from the mercury and the interior of the tube when the barometer is made; but it seems doubtful if, by any means whatever, it can be preserved for a considerable length of time in this state. The most carefully constructed barometers are liable to a slow and gradual deterioration by the intrusion of air, which has been supposed to insinuate itself between the metal and the tube, and not through the mercury. To obviate this inconvenience Professor Daniell conceived the ingenious idea of fixing to the open end of the tube of the cistern barometer a substance having a greater affinity than glass for mercury. "I caused," says he, "a small thin piece of platinum tube to be made, about the third of an inch in length, and of the diameter of the glass tube; this was carefully welded to its open end, so that the barometer tube terminated in a ring of platinum. The tube was filled and boiled as usual, and the infiltration of air was completely prevented by the adhesion of the mercury both to the interior and exterior surface of the platinum guard. I have no doubt that a mere ring of wire welded, or even cemented, upon the exterior surface of the glass, which would be a much easier and less expensive operation, would be a sufficient protection, as the slightest line of perfect contact must effectually arrest the passage of the air." — *Meteorological Essays*, p. 577. He farther states, that though time alone can fully confirm the efficacy of the platinum guard, the experiments, as far as they have gone, have been completely satisfactory.

Corrections necessary. — In all barometic observations there are, in general, two essential corrections to be made; one for the capillarity or depression of the mercury in the tube, and the other for temperature. Pure mercury in a glass tube always assumes a convex surface. The following are the corrections for tubes of different diameters, according to the theory of Mr. Ivory. (*Encyc. Brit.*, art. "Capillary Action.")

Diam. of Tube.		Depression.	Diam. of Tube.		Depression.
Inches.		*Inches.*	*Inches.*		*Inches.*
·10	-	·1403.	·40	-	·0153.
·15	-	·0863.	·45	-	·0112.
·20	-	·0581.	·50	-	·0083.
·25	-	·0407.	·60	-	·0044.
·30	-	·0292.	·70	-	·0023.
·35	-	·0211.	·80	-	·0012.

These corrections, which must always be applied to cistern barometers, show that wide tubes ought to be preferred; in fact, when the diameter of the tube exceeds half an inch, they may be safely omitted. In siphon barometers having both branches of the same diameter, the depression is equal at both ends; consequently the effect is destroyed, and no correction is required. This is a considerable advantage; for notwithstanding the most elaborate calculations, some uncertainty must always remain with regard to the exact amount of the capillary repulsion.

The correction for the temperature, which is the most important, depends on the expansion of the mercury, and the expansion of the scale on which the divisions are marked. If we make $a =$ the height of the thermometer in degrees above the freezing-point, $x =$ the fractional part of its bulk which mercury expands for one degree of heat on Fahrenheit's scale, $y =$ the fractional part of its length by which the scale increases, $h =$ the observed height of the barometer; then the height which would have been observed had the thermometer stood at the freezing point is

$$h - h\,a\,(x - y).$$

The expansion of mercury in part of its bulk is ·0001001. The scale is generally of some mixed metal of which the expansion is not very well ascertained: supposing it to be equal to that of copper, the expansion would be ·0000096; therefore it will be sufficiently accurate to neglect the temperature of the scale, and assume that of the mercury to be ·0001. Hence the following practical rule for reducing an observed height to the corresponding height at the temperature of the freezing point: "Subtract the ten-thousandth part of the observed altitude for every degree of Fahrenheit above 32." Suppose the thermometer 54° and the barometer 30 inches, the correction will be $(54-32) \times 30 \times {\cdot}0001 = {\cdot}066$, to be subtracted from 30 inches. In order to find the value of this correction a thermometer must be attached to the barometer, and observed at the same time. A table, showing the correction for temperature for every degree of Fahrenheit from 30° to 90°, and for every difference of half an inch in the height of the mercury from 28 to 30·5 inches, was constructed by Professor Schumacher, and is given by Mr. Baily in the *Phil. Trans.* for 1837, p. 434.

Cause of the variations of the barometer. — Various theories have been proposed to account for those frequent

atmospherical changes which cause the rise and fall of the barometer, but none of them can be regarded as very satisfactory. Whatever tends to increase or diminish the vertical pressure will obviously cause the barometer to rise or fall; but the vertical pressure may be increased either by an influx of winds and the accumulation of air at any place, or by a diminution of the elasticity of the atmosphere. The presence of heat or of moisture augments the elasticity, and consequently reduces the weight of the vertical column. During the prevalence of northerly and easterly winds the barometer stands high, the elasticity being diminished by the cold. But the real difficulty, Professor Leslie remarks, "consists in explaining why the variations of the barometer should be greater in the high latitudes than between the tropics, and why they should exceed in all cases the quantities which calculation might assign. The only mode, perhaps, of removing the difficulty is to take into consideration the comparative slowness with which any force is propagated through the vast body of the atmosphere. An inequality may continue to accumulate in one spot before the counterbalancing influence of the distant portions of the aerial fluid can arrive to modify the result. In the higher latitudes, the narrow circle of air may be considered as in some measure insulated from the expanded ocean of atmosphere; and hence, perhaps, the variations of the barometer are concentrated there, and swelled beyond the due proportion." — *Encyc. Brit.*

Uses of the barometer.—The barometer is an instrument of great importance in astronomy, its indications forming an essential element in determining the amount of atmospherical refraction. (*See* REFRACTION.) It is also, on account of its application to the measurement of altitudes, indispensable in all researches connected with climate. (*See* HEIGHTS, MEASUREMENT OF.) The purpose for which it is most commonly sought after is to prognosticate the state of the weather. On land this is perhaps the least important of its applications, but the case is widely different at sea. A remarkable instance of its utility to the mariner is given by Dr. Arnott. "The marine barometer has not yet been in general use for many years, and the author was one of a numerous crew who probably owed their preservation to its almost miraculous warning. It was in a southern latitude; the sun had just set with placid appearance, closing a beautiful afternoon; and the usual mirth of the evening watch was proceeding, when the captain's order came to prepare with all haste for a storm; the barometer had begun to fall with appalling rapidity. As yet the oldest sailors had not perceived even a threatening in the sky, and were surprised at the extent and hurry of the preparation; but the required preparations were not completed, when a more awful hurricane burst upon them than the most experienced had ever braved. Nothing could withstand it; the sails, already furled and closely bound to the yards, were riven away in tatters; even the bare yards and masts were in great part disabled, and at one time the whole rigging had nearly fallen by the board. In that awful night, but for the little tube of mercury which had given the warning, neither the strength of the noble ship nor the skill and energies of the commander could have saved one man to tell the tale." (*Elements of Nat. Phil.* vol. i. p. 353.)

No certain rules can be laid down for prognosticating the state of the weather from the barometer. The following, taken from the *Saturday Magazine*, are probably of as general application as any that can be given. It is always to be remembered that what the barometer actually shows is the present pressure of the atmosphere; and that its variations correspond to atmospherical changes which have already taken place, the effects of which may follow their cause at a greater or less interval.

1. After a continuance of dry weather, if the barometer begins to fall slowly and steadily, rain will certainly ensue; but if the fine weather has been of long duration, the mercury may fall for two or three days before any perceptible change takes place, and the longer time elapses before the rain comes the longer the wet weather is likely to last.

2. Conversely, if after a great deal of wet weather, with the barometer below its mean height, the mercury begins to rise steadily and slowly, fine weather will come, though two or three wet days may first elapse; and the fine weather will be the more permanent in proportion to the length of time that passes before the perceptible change takes place.

3. On either of the two foregoing suppositions, if the change immediately ensues on the motion of the mercury the change will not be permanent.

4. If the barometer rise slowly and steadily for two days together or more, fine weather will come, though for those two days it may rain incessantly, and the reverse; but if the barometer rise for two days or more during rain, and then on the appearance of fine weather begins to fall again, that fine weather will be very transient, and *vice versa*.

5. A sudden fall of the barometer in the spring or autumn indicates wind; in the summer, during very hot weather, a thunderstorm may be expected; in winter, a sudden fall after frost of some continuance indicates a change of wind, with thaw and rain; but in a continued frost a rise of the mercury indicates approaching snow.

6. No rapid fluctuations of the barometer are to be interpreted as indicating either dry or wet weather of any continuance; it is only the slow, steady, and continued rise or fall that is to be attended to in this respect.

7. A rise of the mercury late in the autumn, after a long continuance of wet and windy weather, generally indicates a change of wind to the northern quarters, and the approach of frost.

See also the *Phil. Trans.*, No. 187., for Dr. Halley's Rules. Patrick's Rules, which have long been popularly known, were first published in *Harris's Lexicon Technicum*, art. "Barometer."

BA'ROMETZ. The hairy stem of a species of fern or Aspidium, which, from its procumbent position and shaggy surface, looks like a crouching animal; hence called *Scythian lamb*.

BA'RON. The lowest but most ancient title of British nobility. The dignity appears to have been originally territorial. The higher feudatories of England, after the Norman conquest, possessed baronies on which a certain number of knights' fees were dependent, and were bound to attend the king with a certain retinue of knights. But in process of time, many of the barons having lost by alienation great part of their lands, the distinction between *greater* and *lesser barons* began to arise; and the former alone constituted part of the great council of the sovereign, in their own right, until at some early period (supposed to have been about the reign of Henry III.) the practice of summoning individuals to parliament by the king's writ prevailed over the former usage. But this subject is involved in great uncertainty. It has, however, been very generally supposed that the dignity of baron, together with the right to sit in parliament, was at an early period annexed in many instances to the possession of certain lands or castles, which have thus been believed to confer *baronies by tenure*. But Sir Harris Nicolas, in his *Introduction to the Peerage*, gives strong reasons to show, in the first place, that it is by no means clear that persons seised of lands *per baroniam* were entitled to a summons to parliament in the reign of Edward the First; and, in the next place, that there is no positive proof of such a tenure having been legitimately established at any subsequent period. *Baronies by writ* were created by the king's writ of summons to parliament, when addressed to individuals by name. The first thus created were in 49 H. 3., of which two (Despenser and Roos) exist at the present day. Whether, however, the dignity thus created was originally hereditary, admits of a doubt; no words to that effect are found in the ancient writs. But, in point of fact, the next heir was summoned by writ, after the decease of his ancestor, in a great majority of instances; and it has been long settled, that a summons to parliament by the king's writ, addressed to an individual, creates a barony descendible to heirs general. The earliest creation of a *barony by letters patent* took place in the 11th year of Richard II. (that of Beauchamp of Kidderminster); and therefore when a dignity of earlier creation than that year is claimed, it is presumed to have originated in a summons by writ, and consequently to be descendible to heirs general. On the death of a baron by writ without issue male, but with more daughters than one, the barony falls into *abeyance* until only one daughter or the sole heir of one daughter survives. The word Baron (baro, or varo, to which some give a Latin and others a German derivation) appears to have simply signified "man," and in some cases freeman or citizen, in the laws of the Franks and other early nations. In France, the title of baron originally belonged only to those who were immediate vassals of the crown: it afterwards became applied in common usage to those who had the right of executing justice on their fiefs. The title of baron ranked, as in England, after those of duke, marquis, count, and viscount; except in Dauphiné and Britanny, where the baron had precedence of the three latter. In Germany the title of Baron (Freyherr) is extremely common; but a great distinction existed, under the Empire, between the barons who were created by sovereign lords, and the barons of the Empire, the former being those immediate lords who had no voice in the Diet.

BA'RONET, KNIGHT BARONET. The lowest degree of hereditary dignity in England. This order was instituted by King James I. in 1611, as a reward for the services of those who came forward to quell the insurrection in Ireland, and especially in the province of Ulster; each person who received it furnishing a supply sufficient to maintain thirty soldiers for three years. The creation is by patent under the great seal, and generally limited to the heirs male of the body of the grantee, although sometimes otherwise entailed. Baronets rank among themselves according to creation, and come next after the younger sons of barons. By a clause in

the patent of creation, the heir male apparent to the title can claim the honour of knighthood, on attaining the age of twenty-one, in the life of his father or grandfather. Baronets bear for distinction on their paternal coats the arms of Ulster, in a sinister hand, erect, open, and couped at the wrist, gules in a field argent. This augmentation is placed sometimes in the middle chief point, sometimes on the fess point, &c. as may be most convenient, but subject to certain rules of heraldry. Baronets of Ireland were instituted by James I. nine years after the creation of baronets in England, with similar privileges and badge. Baronets of Scotland, or Nova Scotia baronets, were created by Charles I. in 1625, in furtherance of a project of colonization in that part of America. Their badge is the ensign of Nova Scotia. It had long fallen into disuse; but was borne again in 1775, by way of revival of the order.

BA'RONS OF EXCHEQUER. Certain Judges in England and Scotland, to whom the administration of justice is committed in causes between the sovereign and his subjects relating to the revenue. In the former country the Court of Exchequer takes cognizance of private causes also. *See* Exchequer.

BA'RONY. A territorial subdivision in Ireland, which nearly corresponds with the hundred in England. Each barony is supposed to have been originally the district of a native chief. There are in all 252 baronies in Ireland.

BA'ROSCOPE. (Gr. βαρος, *weight*, and σκοπεω, *I observe.*) A term which has been sometimes given to the barometer. According to its derivation it signifies *observer of weight*, and is properly applied to instruments which indicate variations in the weight of the atmosphere, without giving the means of absolutely measuring it. The wheel barometer of Hooke is properly a baroscope.

BA'RRAS. The resin which exudes from wounds made in the bark of fir trees.

BA'RRATRY. A name applied by our law and that of other countries to various offences. In England, a "common barreter" is defined by Lord Coke to be a common mover and maintainer of suits in disturbance of the peace, and in taking and detaining the possession of houses and lands or goods by false inventions. Barratry, in this sense, is an indictable offence at common law. The obtaining benefices at Rome was also an offence of *barratry*. In maritime insurance, barratry is any act of the master or mariners of a criminal nature, or which is grossly negligent, tending to their own benefit, to the prejudice of the owner of the ship, and without his permission. In Scotland, the crime of a judge who receives a bribe for a judgment is called *barratry*.

BA'RREL. An English measure of capacity, varying with the nature of the liquid measured. In the old measures, a barrel denoted 31½ gallons of wine, 32 gallons of ale, or 36 gallons of beer. By a statute of 1 W. & M., the ale and beer barrels were equalized for every part of England except London, and ordered to contain 34 gallons. The term Barrel was formerly in use to denote, in a rough way, other sorts of goods. Thus, a barrel of salmon, 42 gallons; a barrel of soap, 256 pounds. In common language any hollow cylinder is called a barrel.

BARREN FLOWERS. Are those which either have stamens and no pistil, or which have neither stamens nor pistil.

BARRICA'DO. (Fr. barricade.) A defence either by intrenchment or raised work, made in a hasty manner, by barrels filled with earth, heaps of stones piled up, carts, trunks of trees, or any other materials which would obstruct the passage or advance of an opposing force. The famous day of the Barricades at Paris took place on the 12th of May, 1588, when the populace invested the troops of the king, Henry III., in the Louvre, and forced that sovereign to escape from Paris. The Barricades again formed an important feature in the revolution of July, 1830.

BA'RRIER. (Fr. barrière.) A piece of wood work erected to defend the entrance of a passage or intrenchment, with a moveable bar in the centre, which may be removed at pleasure. It is usually erected between the citadel and town.

BARRIER TREATY. In 1713, a negotiation concluded between the Dutch and the King of France shortly before the peace of Utrecht, by which the former reserved the right to hold garrisons in certain fortresses of the Spanish Netherlands.

BA'RRIS. A large baboon of the Guinea coast.

BA'RRISTER. An advocate admitted to plead at the bar in the English courts of common law and equity. Barristers were anciently styled apprentices at law, until their admission to the degree of sergeant. A student intending to be called to the bar must be admitted a member of one of the four Inns of Court (Inner and Middle Temple, Lincoln's Inn, and Gray's Inn), and reside for a certain time, during three years in some cases and five in others. The disputations or arguments (termed exercises) which were formerly required of a student have been reduced to mere matters of form. A barrister has no legal mode of recovering fees for his services.

BA'RROWS, or TUMULI, says Mr. Gough, in his *Sepulchral Monuments*, are the most ancient monuments in the world. The sepulchres of the heroes of the war of Troy are still distinguished, if tradition is to be relied upon, by the mounds raised over them. In these ancient barrows the base is said to have been generally formed of stones, the upper part consisting of a mound of earth. Barrows are found scattered over the plains of the Ukraine and of Tartary, and in great numbers in the Mississippi valley of North America. The barrows of England are supposed to be almost all of British construction; although the mounds properly so called are sometimes confounded with those tumuli found in Roman camps, where they serve as land marks, or for some military purpose. Of the antiquaries who have treated of these relics of ancient eras, Dr. Stukely and Sir R. Colt Hoare are the most eminent. They have been distinguished, according to peculiarities of form and construction, into long barrows, bowl, bell, pond, twin, cone, broad, &c. In the most ancient barrows, the bodies found are deposited within a cist or stone receptacle, with the head towards the north: in those of later date, this direction is not observed. The bones which have been discovered within the numerous barrows that have been opened were generally accompanied by utensils, weapons, &c.; and from the form and finish of these, some conjecture has been made as to the period of the interment. But these barrows, although generally sepulchral, are not uniformly so: in some, bones of animals only have been found. Barrow burial is said by Sir R. Hoare to have lasted from a period of unknown antiquity down to about the eighth century. Barrows are chiefly found in the chalk districts of Wilts and Dorsetshire.

BA'RTER. A rule of Arithmetic by which the values of commodities of different kinds are compared.

BARY'TA. (Greek. βαρυς, *heavy.*) The oxide of barium, composed of 70 barium and 8 oxygen. Baryta is commonly called an alkaline earth. It is of a grey colour, difficultly fusible, and poisonous. It is soluble in about 20 parts of cold water. It forms white salts with the acids, all of which are poisonous except the sulphate. The soluble salts of baryta are excellent tests of the presence of sulphuric acid, which they indicate in solution by a white precipitate, insoluble in water and in acids, and composed of 77 baryta and 40 sulphuric acid; 117 parts, therefore, of pure and dry sulphate of baryta are equivalent to 40 of sulphuric acid. There are only two abundant natural compounds of baryta: the *sulphate*, which occurs crystalline, and the *carbonate*. *Native sulphate of baryta*, *heavy spar*, or *baro-selenite*, is found in this country in Cumberland and Westmoreland; a variety from Derbyshire is provincially called *cawk*. Native *carbonate of baryta*, or *barolite*, was first discovered at Anglesark in Lancashire by Dr. Withering, and hence called Witherite. It occurs crystallised and massive. It consists of 77 baryta and 22 carbonic acid; its equivalent, therefore, is 99.

BARYTO-CALCITE. A mineral found at Alston in Cumberland: it occurs both massive and crystallised in oblique rhombic prisms. It contains about 66 per cent. of carbonate of baryta, and 34 of carbonate of lime.

BA'RYTONE. (Βαρυς, *grave*, and τονος, *tone.*) The male voice, the compass of which is between tenor and base. Also a musical instrument similar to the *viol di gamba*.

BASA'LT. A common species of trap-rock; it is essentially composed of felspar and augite, of a compact texture, and dark green, grey, or black colour. It is often found in regular columns, of which the Giant's Causeway and the Island of Staffa furnish magnificent examples.

BASANI'TE. A variety of silicious slate, sometimes used as a touchstone to determine the purity of gold by the colour of its streak. (From βασανος, *the trier.*)

BA'SCINET, or BA'SINET. A light basin-shaped helmet, worn by the infantry in the reigns of Edward II. and III., and of Richard II. (See *Grose on Ancient Armour.*)

BASE. In Geometry, the lowest side of any figure; as the base of a triangle, of a cone, &c. Any side of a figure may be taken as its base.

Base. A chemical term, chiefly applied to metallic oxides, or to the leading constituent of compounds. Thus, soda is called the base of sulphate of soda; and sodium is the metallic base of soda. Hence the distinction into salifiable and metallic bases.

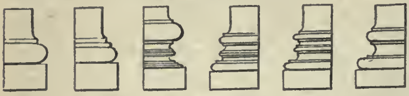
Base. In Music (frequently written Bass), the lowest part in a concert, whether vocal or instrumental. By some it is considered the fundamental or most important part; others regard the melody, or highest part, in that light.

Base, Clef. *See* Clef.

Base, Thorough. *See* Thorough Bass.

Base. (Gr. βασις, *a foundation.*) In Architecture,

generally a body which bears another. In the orders, it is the lower part of a column, moulded or plain, on which the shaft is placed. In the Grecian Doric, the columns are without bases, and stand immediately on the floor or pavement of the portico. The different bases are represented below, including the Attic base.



TUSCAN. ROMAN DORIC. IONIC. CORINTHIAN. COMPOSITE. ATTIC.

BASE'LLA. (A Malabar word.) A turning succulent-leaved Chenopodiaceous plant, native of the tropical parts of Asia, and commonly cultivated instead of spinach in the East Indies.

BA'SEMENT. (From Base.) In Architecture, the lowest story of a building.

BASIGY'NIUM. (Gr. βασις, *the base*, γυνη, *female*.) A stalk rising above the origin of the calyx, and bearing an ovary at its apex, as in Capparis.

BA'SIL. A fragrant aromatic herbaceous plant, the *Ocymum basilicum*, a native of India, whose leaves are much used in cookery for the purpose of giving a savoury flavour to dishes.

BA'SILIC. (Gr. βασιλικος, *royal*.) A pharmaceutical term, formerly applied to certain powders, ointments, &c. of pre-eminent virtues and activity.

BASI'LICA. (Gr. βασιλευς, *king*.) In Architecture, properly the palace of a king; but it afterwards came to signify an apartment which was usually provided in the houses of persons of consequence, where assemblies were held for dispensing justice. The Gordian family in their magnificent country house in the Via Prenestina had three basilicæ, each upwards of a hundred feet long. There was usually a basilica attached to every market for summary settlement of disputes that might arise, and it was surrounded by shops and other conveniences for traders. The difference between the Roman and Grecian basilica is described by Vitruvius, to whose work the reader may refer. We have in the article ARCHITECTURE (*quod vide*) given some account of the rise of the modern basilica for religious uses from the form of the more ancient one. Its form was that of a parallelogram, with a portico at each end, being covered by a roof supported by ranks of columns. Palladio applied the term to those buildings in the cities of Italy somewhat similar in use to our town halls.

BASILI'SCUS. A basilisk. The epithet is applied in Zoology to a most harmless genus of saurian reptiles, of the Iguanoid family, having no femoral pores; but with palatal teeth; a covering of small scales; and an elevated dorsal crest, supported by the vertebral spines, and extending from the neck to the middle of the tail. One of the species (*Basiliscus mitratus*) supports a mitre-shaped crest on the head.

BA'SIN. In Physical Geography, the space of country drained by a particular river; as the Basin of the Thames, Rhine, Rhone, &c. In Geology, depressed portions of strata, forming a hollow surrounded by hills, as the "London Basin," the "Paris Basin," &c.

BA'SIS. *See* BASE.

BASI'SOLUTE. (Lat. basis and solutus, *free*.) A name sometimes applied to those leaves which are prolonged at the base below the point of origin, as in the bracts of *Fumaria*, the leaves of *Sedum reflexum*, &c.

BA'SKET. (Lat. bascauda.) In Architecture, part of the Corinthian capital. *See* CAPITAL.

BASS. *See* BASE.

BASSETTE. (Diminutive of Basso.) In Music, the smallest species of the bass violin.

BASSOO'N. (Fr. basson.) A musical wind instrument made of wood, serving as the proper bass to the oboe and clarionet. The Italians call it *fagotto*, because composed of two pieces of wood *fagotted* as it were together. It is played by means of a bent mouth-piece and reed, and its compass is shown in the synoptical view of the different instruments at the end of the article MUSIC.

BASSO RILIEVO. *See* RILIEVO.

BASSO'RINE. A modification of gum, originally discovered by Vauquelin in gum bassora.

BA'STARD. A word of which the etymology is entirely uncertain. By the ancient legal course of precedent in England, the fact of birth during the marriage of the parents, or within a certain time after the death of the husband (extended in some cases to a great length, as in that of the Countess of Gloucester, temp. E. 2., to one year and seven months), was conclusive in favour of legitimacy. But this fact is now held to amount only to strong presumptive evidence, repellable by proof of non-access. The legal incapacities of an illegitimate child, by the law of England, relate wholly to the powers of inheritance and succession, to which he is in no respect entitled either as to real or personal property. In case of a divorce "a vinculo matrimonii" in the spiritual court, children born during the marriage are bastards by the law of England. The Scottish law is less strict in favour of legitimacy than that of England. Two species of legitimation have been adopted in it from the civil law: one, "per subsequens matrimonium," by the subsequent intermarriage of the parents (but a child born in Scotland, and legitimated by subsequent intermarriage in Scotland, is not entitled to succeed to real property in England; and, if born in England, remains a bastard to all intents and purposes); and, secondly, "per rescriptum principis," by letters of legitimation from the crown.

BASTARD STUCCO. In Architecture, plastering of three coats, whereof the first is usually roughing in, or rendering; the second floating, as in trowelled stucco; and the third or finishing coat contains a small quantity of hair besides the sand. Bastard stucco is not hand-floated, and the trowelling is done with less labour than what is called trowelled stucco.

BASTARD WING. (*Alula spuria*, Linn.) Three or five quill-like feathers, placed at a small joint rising at the middle part of the wing.

BASTI'LLE. In France, in the middle ages, towers and other outworks erected without the limits of towns were so called. The famous Bastille of Paris was an edifice of the same description, originally erected outside the city, near the modern Porte Saint Antoine. It was built by Hugues Aubriot, prévot des marchands, in 1369; and he is said to have been the first prisoner of state confined in it after it was employed for that purpose. The Bastille was taken by the people of Paris on the 14th of July, 1789, and demolished.

BASTINA'DO. (Ital. bastonnata, from bastone, *a stick*.) An ordinary mode of punishment in oriental countries, especially China, Turkey, and Persia. It is commonly inflicted upon the soles of the feet. According to the Turkish law, slaves and *rayahs* or tributaries alone are liable to it; but no such limitation is observed when the temper of a magistrate possessing summary authority is inflamed. This punishment is termed *zarb* in Turkish. It is extremely severe, although limited by law to the Jewish number of 39 blows, or 75 in some aggravated cases; but this regulation, like the other, is little observed in practice. (See generally, as to this species of infliction in penal law, the essay of Lanjuinais, *Sur la Bastonnade et la Flagellation penales*.)

BA'STION. A large projecting mass of earth or masonry at the angles of a fortified work, anciently called a bulwark. The modern bastion consists of two flanks, serving for the defence of the adjacent curtains, and two faces, making with each other an angle of 60° or upwards, which command the outworks and the ground before the fortification. The space between two bastions is called the curtain. The use of the bastions is to bring every point at the foot of the rampart as much as possible under the command of the guns, so that on whatever point a besieging army approaches it may be attacked sideways.

BAT. *See* VESPERTILIO, DERMOPTERA, CHEIROPTERA.

BATA'TAS. A species of convolvulaceous plant, *Convolvulus batatas*, a native of the East Indies, with fleshy sweet tubers. It is much cultivated for the sake of the latter in all the hotter parts of the world, where they are much esteemed as an article of food. Its name has now been popularly transferred to the potatoe, which has expelled it from cultivation in all temperate climates.

BATH. (From the Saxon bað.) In Architecture, a place for bathing. Among the ancients, the public baths were of very considerable extent, and consisted of a great number of apartments. These prodigious monuments of Roman magnificence seem to have been borrowed in some respects from the gymnasia of the Greeks, both the one and the other being instituted with a view to the exercise and health of the people. The word *thermæ*, which the Romans called these edifices signifies a place for the reception of hot baths; but both hot and cold were generally comprised in the same building. In later times, the Romans used the bath before they took their supper. The rich usually had hot and cold baths in their own houses, and it was not till the time of Augustus that the baths assumed an air of grandeur and magnificence. Different authors reckon nearly eight hundred baths in Rome. The most celebrated were those of Agrippa, Antoninus, Caracalla, Diocletian, Domitian, Nero, and Titus. Those of Diocletian are said to have been capable of accommodating eighteen hundred bathers. The vestiges of these stupendous buildings indicate the amazing magnificence of the age in which they were erected. Their pavements were mosaic; the ceilings vaulted, and richly gilt and painted; the walls encrusted with the rarest marbles. Many examples of ancient Greek sculpture have been restored to the world from these edifices. It was from the recesses of these buildings that Raphael took the hint for his decorations of the Vatican, and

largely from these resources drew the first restorers of the art.

BATH. In Chemistry, heated sand is often used as a medium for communicating heat, as glass and other vessels may be conveniently placed upon or immersed in it: sometimes water is used in the same way; hence *sand bath, water bath*, &c. The water bath is called by the old chemists Balneum Mariæ, and often abbreviated B.M.

BATH, ORDER OF THE. A British order of knighthood. On the day of his coronation, Henry IV. conferred the dignity of knighthood on forty-six esquires who had watched during the previous night, and bathed themselves, in pursuance of a very ancient custom, derived from the usages of the ancient Franks. It was usual, from this period, to make similar creations of knights on royal coronations, espousals, and similar solemnities; but the custom was discontinued after the coronation of Charles II., until George I., in the eleventh year of his reign, instituted the present order of the Bath by letters patent. It consisted, exclusive of the sovereign, of a grand-master and thirty-six companions; and was a military order. In 1815, the order was greatly extended (after several intermediate alterations), and is now composed of three classes — military and civil knights grand crosses, knights commanders, and knights companions, — who do not take the title or privilege of a knight bachelor, but take precedence of esquires. The badge worn by the grand crosses is now a golden cross of eight points, enamelled white, with a lion of England between the four principal angles; on the centre a sceptre erect, or, having on the sides a rose, thistle, and shamrock, engrafted between three imperial crowns proper, encircled with a riband gules; thereon the motto of the order, " Tria juncta in uno." They also wear a silver star. The badge of the knights commanders is the same with that of the knights grand crosses, but smaller; their cross somewhat different. The companions have only the badge without a star.

BA'THOS. (Gr. *βάθος, depth.*) A word invented to signify a ludicrous descent, in rhetoric, from elevated to mean thoughts. (*See* CLIMAX.) It has been chiefly rendered popular by Pope and Arbuthnot's jeu d'esprit, the " Treatise on the Bathos, by Martinus Scriblerus."

BATI'DEÆ. A small division of Urticaceous plants, containing but one genus, Batis, after which it is named. It yields soda in great quantity.

BA'TOLITES. A genus of fossil shells, considered by Cuvier as *hippurites.*

BA'TON. (Fr.) In Music, a term denoting a rest of four semibreves.

BATON is also the staff of a field marshal.

BA'TONNI'ER. (Mod. Lat. bastonarius.) In French, the elected president of an order or fraternity. The *batonnier* of the order of advocates is elected by the whole body. In ancient times he carried in their processions a staff (baton) with the flag of Saint Nicholas, whence the name. He is president of the council of discipline.

BATRA'CHIANS, BATRACHIA. (Gr. *βάτραχος, a frog.*) An order of Reptilia, including the frogs and toads, and all reptiles which, like them, have naked skins and external branchiæ, in the early stage of existence; those batrachia which retain the gills or gill-apertures throughout life are called "perennibranchiate," or " amphibious."

BA'TRACHOMY'OMA'CHIA. (Gr. *βατραχομυομαχία.*) *The Battle of the Frogs and Mice*, a mock heroic poem which has come down to us, and is attributed to Homer; but there is no probability that it was written by the author of the Iliad or Odyssey.

BA'TRACHOSPE'RMA. (Gr. *βάτραχος, a frog*, and *σπέρμα, seed.*) A name proposed for such Algaceous genera as are articulated and live in fresh water.

BATTA'LION. A division of the infantry in an army, composed of a variable number of men: at present, in the English service, it is about 750. One battalion generally constitutes a regiment; but some, as those of the Guards, consists of two battalions, and a regiment of artillery of eight. Each battalion is generally divided into ten companies; it is commanded by its own colonel; and several battalions or regiments are, on service, all united under one general officer, forming a brigade.

BA'TTARDEAU. (Fr. battre, and eau.) In Architecture, the same as *Cofferdam*, which see.

BA'TTEN. (Probably from the French bâton, from its slender width.) In Architecture, a name given by workmen to slips of wood, from two to four inches broad and one inch thick; the length considerable, but undefined.

BA'TTENED DOWN. Covering the hatchways in very bad weather with strong gratings, and these with painted canvass nailed under long pieces of wood (battens), to keep the water from getting below the decks.

BA'TTENING. (From batten.) In Architecture, narrow battens fixed to a wall, to which the laths for the plastering are nailed.

BA'TTER. (Probably from battre, Fr.) In Architecture, a term used by artificers to signify that a body does not stand upright, but inclines from you when you stand before it; when, on the contrary, it leans towards you, they describe its inclination by saying it overhangs.

BA'TTERING-RAM. An ancient military engine employed for beating down the walls of besieged fortresses. It consisted of a long heavy beam of timber, armed with iron at one extremity, and the effect was produced by pushing it violently with successive blows against the wall. The *ram* was worked in various ways. Sometimes it was simply supported by two files of soldiers, and the impetus given by a simultaneous thrust. More frequently it was slung from a cross beam, supported by two posts, by a rope or cable about its middle; in which case it had an oscillating motion, like a pendulum. A third sort was moved on rollers or wheels. Generally they were worked under a cover or shed (*vineæ* or *testudines*) to protect the assailants. These machines were often of immense size, and exceedingly ponderous, requiring 100 men to work them. Justus Lipsius describes a battering ram as 180 feet long, and two feet four inches in diameter, armed with an iron head weighing at least a ton and a half. The momentum of this ram, pushed forward by the united strength of 100 men, must have been equal to that of a 36-pound shot discharged point blank from a modern piece of heavy ordnance, and its efficacy in communicating a shock to the whole building very much greater.

BA'TTERY. A military term, denoting any raised place where cannon or mortars are planted. Batteries have various names, according to the different kinds of artillery employed, or the purposes they are designed to effect. *Breach batteries* are used to attack the face of a bastion, in order to make an accessible breach. *Batteries en echarpe* are those which play obliquely. *Ricochet battery*, one from which cannon are discharged with a very small quantity of powder and a little elevation, so as to carry the ball just over the parapet, where it rolls along the opposite rampart, and produces a destructive effect. They are placed perpendicular to the line to be enfiladed. In a ricochet battery, small mortars and howitzers are frequently used with effect in enfilading an enemy's ranks.

BA'TTLE. (Fr. bataille.) In the art Military, an engagement between two hostile armies for the accomplishment of some important object. A battle is the most important event in war: it is the consummation to which all the previous combinations of a general necessarily tend; it is that grand act of war which may decide the fate of kingdoms and of nations as well as that of armies and campaigns. In the early ages of the world a battle was merely a fierce and bloody struggle, the issue of which depended more on the physical strength of the combatants than on any scientific combinations which the general could adopt; but as the arts and sciences progressed, the military system was improved; and the battle of Marathon (the first well authenticated battle in profane history) demonstrated how far superiority in physical strength may be compensated by generalship and discipline. A further illustration of this fact is afforded in the subsequent battles of Platæa, Mantinea, and Leuctra, among the Greeks; and the banks of the Ticinus, the lake of Thrasymenus, and above all the plains of Cannæ, are memorable for engagements, which for ingenuity of design and dexterity of execution have excited the admiration of soldiers in every age. But to give even a faint sketch of the various exploits which were achieved by the Grecian so called *oblique* system, the Macedonian phalanx, and the Roman legion, and of the different military principles involved in their construction, would be to furnish a history of these different nations; and we must content ourselves with referring the reader to the article " Bataille," in the *Encyclopedie des Gens du Monde*, where some concise though scientific details upon this subject will be found. Though the weapons employed in battle in modern times are widely different from those in use among the ancients, and though many circumstances have combined to give an entirely different aspect to the military systems of the two periods, still it is surprising how strong a resemblance to each other is displayed in their ground-work; and it will be found on examination that the grand principles which even in the present century were adopted by Napoleon and the Duke of Wellington were practised, though imperfectly, by Epaminondas on the field of Leuctra. Indeed, it is a circumstance worthy of note, that the changes which in every age have taken place both in the manners and the weapons of nations have had no perceptible influence on the grand leading principles of military tactics. " Les tétrarchies," says a French author, "et les manipules sont representés chez les modernes par les compagnies: les xénagies ou syntagmes et les cohortes Romaines, par les bataillons; enfin, les phalanges et les légions, par les regimens, les brigades ou les divisions." There are three combinations of which a battle is susceptible: — 1. *Defensive*, which consists in taking up a position, and

defending it against the enemy. 2. *Offensive*, in which the enemy is sought to be harassed at all points and on all occasions. The third is a medium between these two, and presupposes on the part of the general sufficient skill to know when to make an attack, and when to act on the defensive. It is impossible to state precisely the principles which should guide a general in the adoption of one or other of these three systems, from the difficulty of providing against unexpected events which often occur to perplex or overturn the most matured and ingenious plans; but making due allowance for casualities of this nature, a reference to history will prove that design and ingenuity have generally triumphed over chance and accident; and that a skilful disposition of the troops, and the seizure of the proper moment for assuming the initiative, combined with courage and adroitness in prosecuting success, will ultimately be crowned with victory. For a full and elaborate view of the principles involved in a battle, the reader may consult with advantage *Jomini's Traité des Grandes Operations Militaires* (Paris, 1824); a system which is founded on the united principle of a *concentration of the forces*, and the *commencement of hostilities*.

BA'TTLE-AXE. A military weapon, which is purely offensive, and owes its origin to the Celtæ. It was not employed by the Greeks and Romans, though it was found among contemporary nations. At the siege of the Roman capitol by the Gauls under Brennus, the most distinguished warriors were armed with battle-axes; and Ammianus Marcellinus states, that this instrument formed part of the offensive armour of the Gauls from time immemorial. In England, Scotland, and Ireland, the battle-axe was much employed: the Lochaber axe, in particular, was long a formidable implement of destruction in the hands of the Scottish Highlander, and obtained almost a universal reputation.

BA'TTLEMENTS. (From battle.) In Architecture, a wall or parapet on the top of a building, with embrasures or open places to look through, or discharge missiles for the annoyance of an enemy.

BATTUE. (Fr.) In Sporting, a term indicating a practice of huntsmen which consists in encompassing a certain portion of the forest, and in endeavouring, by beating the bushes and with loud exclamations, to bring out wolves, foxes, or other animals of the chase.

BATTU'TA. (It. *a beating*.) In Music, the motion of beating with the hand or foot in directing the time.

BAUERA'CEÆ (so called from Mr. Bauer, their discoverer), a small natural order of New Holland shrubs with pretty purple flowers, related to *Saxifragaceæ*. There is but one genus.

BAULK. (From the Dutch.) Sometimes called Dram Timber. In Architecture, a piece of whole fir, being the trunk of a tree of that species of wood usually squared for building purposes. In the metropolis the term is only applied to small lengths from 18 to 25 feet, mostly under 10 inches square, tapering considerably, and with the angles so left that the baulk is not an exact square.

BAXTE'RIANS. In Ecclesiastical History, a name applied to those English theologians who adopted the sentiments of Richard Baxter on the subject of grace and free will, forming a sort of middle way between Calvinism and Arminianism. They never formed, strictly speaking, a sect, and the name is now disused: nevertheless, similarly modified religious opinions are common among nonconformists at this day.

BAY. (From the Dutch baye.) In Architecture, a division of a barn or other building, generally from 15 to 20 feet in length or breadth. In plasterers' work it is the space between the screeds prepared for regulating and working the floating rule. *See* SCREEDS.

BAY. (Fr. *baie*, Ital. *baia*, Span. *bahia*.) In Geography, a portion of the sea, inclosed between two capes or headlands, so that the opening is the widest part and the inlet gradually narrows within. It is thus distinguished from *gulf*, in which the opening is comparatively narrow. The distinction, however, is not always observed in nomenclature; *e. g.* Baffin's Bay, and Chesapeake Bay in America, are both more properly gulfs.

BA'YONET. A short triangular sword or dagger fixed upon the muzzle of a musket, which is thus transformed into a thrusting weapon. The original invention and subsequent improvement of the bayonet are due to the French, who first used it in the Netherlands in 1647, and the advantages which this weapon gained to that nation soon attracted notice to its merits. In the beginning of the eighteenth century, it was every where substituted for the pike, and in some instances it has decided the issue of an engagement without a single shot being fired. Many plans have been devised at different times to augment the efficiency of the bayonet, by turning it to the purposes of tilting and fencing; but when the cumbrousness of the instrument to which it is attached is considered, it will not seem surprising that all schemes of this nature have proved abortive. Cavalry are often counted by *horses*, and infantry by *bayonets*. (See *Guibert's Essai général de Tactique*.)

BAY SALT. (*See* SALT.) A large grained salt, obtained by the spontaneous evaporation of sea water in large shallow pits (bays) exposed to the full influence of sun and air; all coarse-grained salt is frequently known under the name of *bay salt*.

BAZA'AR. (From an Arabic word, signifying traffic or merchandise.) A large square or street where merchants in eastern countries have their shops or warehouses.

BDE'LLIUM. An African gum resin of a bitter nauseous taste, and a dark-brown colour. It is sometimes mixed with myrrh.

BDE'LLOSTOMES, BDELLOSTOMA. (Βδάλλω, and ςτομα, *a mouth adapted for suction*.) A genus of Cyclostomous fishes.

BEACH. In Geography, a shelving tract of sand or shingle washed by the sea or a freshwater lake, and interposed between the water and the land on which vegetation grows. The beach of the ocean is, generally speaking, little more than the space between low and high water mark; the beach of a lake, that between the water marks of the highest and lowest ordinary level of the lake. An inland sea without tide, such as the Mediterranean, has generally little beach, except on flat coasts, where the waters are apt to rise and fall considerably, according to the prevailing winds. *Raised beaches* exhibit a curious phenomenon in geology: they are tracts of shingle and gravel, indurated for the most part into the consistency of puddingstone or breccia, found on the sides of shelving ground at a level above that of some neighbouring lake or sea, in such a position as to leave no doubt that they had in ancient times been washed by its waters. They are found extending along large tracts in the vicinity of the great American lakes.

BE'ACON. (Sax. beacn or beacen, allied to the words *beck*, *beckon*, *i. e.* to point out, in the English language.) A fire lighted by way of signal on a height, or the place where such signals are usually made. Along the southern coast of England, many of the highest hills are provincially termed "beacon," from this circumstance. There is a celebrated poetical description of the transmission of news by fire signals, from height to height, in the *Agamemnon of Æschylus*. The English beacons were erected under the superintendence generally of the lord high admiral; they were usually pitch boxes, or fire pots, and their maintenance and watching was defrayed by a rate levied on the county. (See *Archæologia*, vols. i. and viii.)

BEAD. (Sax. beade.) In Architecture, a moulding whose vertical section is semicircular.

BEAK. In Botany, a hard sharp termination of any part of the fructification. It is Latinized by rostrum.

BEAM. (Sax. beam, *a tree*.) In Architecture, an horizontal piece of timber, used to resist a force or weight; as a tie beam, which acts as a string or chain by its tension; as a straining piece, where it acts by compression; as a bressummer, where it bears an insisting weight.

BEAM. In sea phrase, the width of a vessel. Thus a wide vessel is said to have *more beam* than a narrow one; the beams being the strong pieces of timber stretching across the ship from side to side, for the purpose of supporting the decks and retaining the sides at their proper distance. When a ship is lying entirely on her side, she is said to be *on her beam ends*. When this is the case in a hurricane or heavy gale, there is often no other resource to *right* the ship than cutting the masts away.

A-beam. In the direction perpendicular to the ship's length, a-midships. Thus an object seen from the middle of a vessel, 90 degrees or 8 points from the head or stern, is said to be a-beam.

BEA'MFILLING. In Architecture, the filling in masonry or brickwork between beams or joists, its height being equal to the depth of the timbers filled in.

BEAM-TREE. A deciduous British tree of small growth, inhabiting the mountainous parts of the country, and resembling a small apple tree, with berries like those of the mountain ash. Its leaves are strongly veined in a plaited manner, and white underneath; the wood is hard, compact, and tough, and is used for axletrees, naves of wheels, and cogs of machinery. The *Pyrus aria* of botanists.

BEAR. *See* URSUS.

BE'ARBERRY. The *Arctostaphylus uva ursi*. The leaves of this plant, under the name *uva ursi*, are used as an astringent and tonic in medicine.

BEARD. (*See* BARBA.) When applied to corn it is used in the sense of *Awn*, which also see.

BEARD. The gills or breathing organs of the oyster and other bivalves are vulgarly so called.

BE'ARER. (Sax. bapan, *to bear*.) In Architecture, any upright piece used to support another.

BE'ARING. In Geography and Navigation, the direction or point of the compass in which an object is seen; thus an object *bears* north, south, &c. when seen in these directions. When the distance of an object or point of land is specified besides the bearing, the place of the ship with respect to such object is obviously fixed; thus, the Land's

End N. 48°, E. 141 miles, determines the ship to be 141 miles in the S. 48° W. direction, or nearly south-west from the Land's End.

BEAR'S FOOT. *See* HELLEBORUS.

BEASTS. As charges in Heraldry, are said to be rampant, when represented rearing; sejant, when seated; statant, when standing; couchant, when lying; salient, when springing; passant, when walking (but the words *lodged*, *springing*, and *tripping*, are used of a beast of chase in these positions); gardant, when full-faced; regardant, looking back; dormant, sleeping; nascent, rising out of the middle of an ordinary; issuant, rising from its top or bottom. Two animals represented side by side, but moving in opposite directions, are said to be counter-passant, &c.

BEAT. (Beatan, *to beat.*) In Music, a reversed shake without a turn.

To *beat*, *beat up*, or *beat to windward*, in Navigation, making progress against the wind by a zigzag course, and is the same as working to windward.

BEAU IDEAL. (Fr.) In Painting, that beauty which is freed from the deformity and peculiarity found in nature in all individuals of a species. All the objects which nature exhibits to us have their blemishes and defects, though every eye is not capable of perceiving them; and it is only by long habit of observing what any objects of the same kind have in common that it acquires the faculty of discerning what each wants in particular. By such means the artist gains an idea of perfect nature, or what is called the *Beau Ideal*. *See* IDEAL.

BEAU'TY (Fr. beauté.) In the Fine Arts, that result of all the various perfections whereof an object is susceptible, which pleases the senses, and more particularly the eye and the ear. With the painter and sculptor nature, refined by selecting from the most perfect of the species, is the index and guide; but with the architect the creative power of nature herself is the model of imitation. Some of the sources of beauty have been seriously considered by no less a writer than Burke as consisting in smallness, smoothness, delicacy, and the like; but such speculations are too absurd for notice here. The primary source of all beauty in the three arts is *form*; on that alone must the artist depend if he would produce a work capable of pleasing. There is no doubt that in painting colour is a handmaid that decks her works with many charms; but they are all subordinate to that great effect which form, unaided by all accessaries, is capable of producing on the mind. As form is constituted by lines, it seems probable that an inquiry into their nature might lead the artist to the invention of beautiful forms; and it was doubtless this feeling which led Hogarth, in his *Analysis of Beauty*, to place so much to the account of the serpentine line. But in the arts generally the principles are infinitely more extended; for lines which, from their propriety in one art, are strikingly beautiful, become absolutely absurd as sources of beauty in others. Hence we arrive at one general conclusion, that in all of them fitness for the purpose and proportion to effect the object are the surest guide to beauty of line, and thence naturally to beauty of form. If this be so, no general laws save those dependent on fitness and proportion can be laid down; and perhaps it would not be a difficult task to trace to them all those associations which seem to be connected with the subject in its effect on the mind. Alison, in his elegant *Essays on the Nature and Principles of Taste*, appears to be much impressed with the feeling we have on this point; for he observes that "if there were any original and independent beauty in any *particular* form, the preference of this form would be early and decidedly marked both in the language of children and the opinions of mankind." We trust it may not be irreverent to close this article with a quotation which is as expressive of our notions of beauty as resulting from form as the inspired writer knew it to be true of qualities: "All flesh is not the same flesh; but there is one kind of flesh of men, another flesh of beasts, another of fishes, and another of birds. There are also celestial bodies, and bodies terrestrial; but the glory of the celestial is one, and the glory of the terrestrial is another."

BE'AVER. *See* CASTOR.

BE'CHICUS. (Gr. βὴξ, βηχὸς, *a cough.*) A medicine for the relief of coughs.

BED. (Sax. beð.) In Architecture, the horizontal surface on which the stones or bricks of walls lie in courses.

BED OF A STONE, BRICK, OR SLATE. In Architecture, the lower surface.

BE'DCHA'MBER, LORDS OF THE, or, as they were called before the accession of the House of Hanover, *Gentlemen of the Bedchamber*, are officers of the royal household, under the groom of the stole; their number has usually been twelve, and they wait in turn, a week each. This office is performed by *ladies* during the reign of a queen.

BED MOULDING. In Architecture, those mouldings in all the orders which are between the corona and frieze.

BED OF JUSTICE. (Fr. lit de justice.) In French History, a solemn proceeding to which the monarchs of France had recourse on particular occasions. As is well known, the parliament of that country had a right to resist any commands or decrees issued by the sovereign. If, however, the king insisted on the fulfilment of his wishes, he proceeded to hold a "lit de justice:" *i. e.* he went in person to parliament, attended by the chief officers of the court, and there, mounting the throne (called in the old French language "lit"), caused those commands or decrees which the parliament had rejected to be registered in his presence. This had the effect of intimidating the parliament into compliance; and the means which it usually adopted to intimate its dissatisfaction was to enter a protest against the whole proceeding.

BEDS. In Geology, seams of strata, thick or thin.

BEE. *See* APIS.

BEECH. One of the forest trees of the north of Europe, the *Fagus sylvatica* of botanists, belonging to the natural order *Corylaceæ*. Its fruit, or mast, consists of triangular nuts enclosed in a spiny husk or cupule, of the same nature as the cup of the acorn, only of a different shape, and covering the nuts all over. Its wood, which is hard and rather handsome, is brittle and perishable, and particularly liable to become wormeaten. It is chiefly used by turners and millwrights. The purple and copper beeches seen in plantations are seedling varieties of *Fagus sylvatica*.

BEE-EATER *See* MEROPS.

BEEF-EATER. (By corruption from the French *beauffetier*, an officer appointed to watch the beauffet, buffet, or side-board.) A popular appellation for the yeomen of the king's guard, partially derived from the circumstance that some of them originally were ranged at table on solemn festivals.

BEE'LZEBUB. (Heb.) A god of the Philistines, who had a famous temple at Ekron. His name signifies literally the destroyer of flies; and if we consider the torment which those insignificant insects occasion in the East, it will not seem surprising that the Philistines conferred on him this appellation. Besides, it is quite in conformity with the practice of other idolatrous nations to consider their gods as the destroyers of offensive vermin. Take, for instance, the Apollo Σμινθευς (the destroyer of rats) of the Greeks. Milton in his epic poem assigns him the second rank; and in the second book, where he is represented as rising to address the fallen angels, there is an air of majesty in his demeanour nowhere surpassed.

BEER. (From the German *bier.*) The wine of grain. It is usually made by fermenting an infusion of barley malt and of hops, and bears different names according to its strength and colour. It is nutritious from the sugar and mucilage which it contains, exhilarating from the spirit, and strengthening and narcotic from the hops. Mr. Brande obtained the following quantities of alcohol from 100 parts of different beers: — Burton ale, between 8 and 9; Edinburgh ale, 6 to 7; Dorchester ale, 5 to 6; the average of strong ales being between 6 and 7; brown stout, 6 to 7; London porter, about 4 (average); and London brewers' small beer between 1 and 2. *See* FERMENTATION.

BEET. (Celt. bett, *red.*) The sweet succulent root of *Beta vulgaris*, a Chenopodiaceous plant of biennial duration. It is used in the winter as a salad, for which purpose the red and yellow beets of Castelnaudari are the best; for the food of cattle, under the name of mangel wurzel; and for the extraction of sugar: for the last object a white-rooted variety with a purple crown is the most esteemed. Sea beet, *Beta maritima*, is a well-known and excellent substitute for spinach.

BE'ETLE. (Sax. bytel.) In Architecture, a large wooden hammer or mallet, with one, two, or three handles, for as many persons, with which piles, stakes, wedges, &c. are driven.

BEETLE. A name commonly given to the insects of the Coleopterous order, especially to such as are of a dark or obscure colour; it is also applied, but improperly, to the common pest of our kitchens, the blatta, or cockroach, which is an insect of the Orthopterous order.

BEGHA'RDS. A German word, signifying one who begs with importunity. In this sense, it was frequently applied to the Franciscan and other mendicant orders, denoting the practice by which they gained their subsistence. The Beghards formed a sort of intermediate class between the monks and laity, and were known under various denominations; as the tertianes or half monks of the mendicant orders, the fraternity of the weavers, the brethren of St. Alexius, &c. But the term has also been affixed to a set of persons who, in the thirteenth century, became notorious for the frequency and ardour of their prayers.

The BEGUINS were a class of women throughout Germany and the Netherlands, who as early as the eleventh century, without taking vows or following the rules of any order, united themselves for devotional and charitable purposes, and were distinguished from the great body

of the laity of those times by their industrious, pious, and secluded habits, and by their attention to the education of the young. Their conduct was imitated by men, who formed a union for similar purposes, and were called Beghards (see above). The Beguins continued to exist in Germany up to the Reformation, under the name of "seelen weiber" (spiritual women), from the interest they took in the spiritual concerns of their sex; and a society of them was even seen at Louvain, in the Netherlands, towards the close of last century. There are now in some Roman Catholic countries societies or beguinages of females, who live together after the manner of nuns without taking vows; but, by their mode of life and profession, maintaining the same intermediate state between the laity and the clergy which was first remarkable in the Beghards and Beguins of the eleventh century. The most celebrated is at Ghent.

BEGONIA'CEÆ. (Begonia, the principal genus.) A natural order of Polypetalous Exogens, with showy pink or white flowers and handsome succulent leaves, which are frequently richly coloured or gaily variegated, and have one side considerably larger than the other. Their leaves have large stipules, and a subacid flavour. Much difference of opinion exists among botanists as to their affinity. They generally inhabit the dampest parts of the tropics, and are favourites with cultivators both for their beauty and the facility with which they are maintained, in health.

BEHE'MOTH. (Hebrew.) The name of an animal, of which some of the characters and attributes are described in poetical language in the 40th chapter of the Book of Job. Much pains have been taken to identify the creature here referred to; but it must be remembered that the discovery and general adoption of a mode of description which combines at once exactness with brevity, and is applicable only to the object described, are the results of a recent and highly advanced state of zoological science. Even the prosaic, and, so far as they went, scientific descriptions of animals in the writings of Aristotle, are rarely so copious and precise as to enable a modern naturalist to identify the existing species there referred to. But the aim of Job in the verses in which he sings of *Thau*, *Leviathan*, *Behemoth*, was to show forth the power and wisdom of the Deity, and lower the pride of man, by appealing to the wonderful powers assigned to some of the most remarkable and formidable objects of animated nature with which he was acquainted; and it can hardly therefore be expected that curiosity, eager to hunt out the precise species alluded to, should be gratified. Sufficient source of doubt has always been left to shake the most sagacious conjectures; and some recent inquirers into Biblical zoology, perceiving that the properties of Behemoth were not manifested to the letter in any known existing species, have endeavoured to make the scriptural allusions square with the characters of one of the gigantic extinct animals which the study of fossil remains has brought to light: the *Iguanodon*, for example, a supposed herbivorous reptile, with a horn on the nose and a long and flexible tail, has been selected as the species described by Job. The allusion, in verse 17., to a part of the generative organs, which is visible externally only in the class of mammalia, renders it very improbable that Behemoth could be one of the Reptilia. The exclamation, also, "Behold he drinketh up a river and hasteth not! He trusteth that he can draw up Jordan into his mouth," could not with any appearance of truth be applied to a species of a class of animals of which the organization requires them to drink so little and so seldom. If a mammiferous quadruped, then Behemoth was a herbivorous and ungulate species: "He eateth grass as an ox" (verse 15.); but, unlike the males of the larger ruminants, he had not a divided scrotum, for "the sinews of his stones were wrapt together" (verse 17.) Thus from the few zoological characters which are brought under our consideration, we come to the conclusion that some huge pachyderm, "whose haunt was in the fens, whose place of retreat was encompassed by the willows of the brook, and overshadowed by trees, was "the chief of the ways of God," in the language and mind of the sacred poet.

As there exist differences of opinion among the best Hebrew scholars as to the exact signification of the first part of verse 17., which some have rendered "He sitteth up," and of the second part of verse 19., where allusion is made to some weapon, these become obviously unsafe elements, in the consideration of the zoological problem.

BELE'MNITES. (Gr. βελεμνον, *a dart.*) A genus of fossil Dibranchiate Cephalopods, the shells of which are chambered and perforated by a siphon, but internal. They are long, straight, and conical; and commonly called "thunder stones." These fossil remains are often found in chalk.

BEL-ESPRIT. (Fr.) A term formerly naturalized in England, applied to those individuals whose conversation or writings display an agreeable sprightliness or vivacity. (*Dict. Aca. Franç.*)

BE'LFRY. (Sax. bell, and Lat. ferre, *to carry.*) In Architecture, a tower or other place in which bells are hung. *See* CAMPANILE.

BE'LIAL. A Hebrew word, signifying wicked, worthless, and unprofitable. In Scripture, the sons of Eli are called sons of Belial, for their idolatrous and criminal conduct (1 Sam. ii. 12.); and likewise the inhabitants of Gibeah, who abused the prophet's wife. (Judg. xix. 22.) The apostle Paul (2 Cor. vi. 15.), in order to indicate in the strongest terms the high degree of virtue after which the Christian should strive, places Christ in direct opposition to Belial. Our own epic poet has immortalized the infamy of Belial, by assigning him a prominent place in his *Paradise Lost.*

> A fairer person lost not heaven; he seemed
> For dignity composed, and high exploit.
> But all was false and hollow, though his tongue
> Dropped manna, and could make the worse appear
> The better reason, to perplex and dash
> Maturest counsels, for his thoughts were low:
> To vice industrious, but to nobler deeds
> Timorous and slothful, &c.

In the *Paradise Regained*, Milton represents even Satan as fired with indignation at the impiety of Belial, and as administering to him a sharp rebuke. (*Vide* Addison's Critique on Milton in the *Spectator.*) To these quotations may be added an allusion to Belial by Wierus. (*Pseudomonarchia Dæmonum*, p. 919.) "Sunt quidam necromantici qui asserunt ipsum Salomonem, quodam die astutiâ cujusdam mulieris seductum, orando se inclinâsse versus simulacrum Belial nomine."

BELL. A vessel or hollow body of cast metal, formed to emit sound by the act of some instrument striking against it. Bells are probably of very ancient origin; they are mentioned as worn upon the high priest's robes, in the book of Exodus (ch. xxviii. ver. 3.) They were used among the Greeks in camps and garrisons. Church bells are said to have been invented by Paulinus, bishop of Nola in Campania (whence the term Campana), about the year 400. They are first mentioned in England by Bede, towards the end of the seventh century.

BELLA DONNA. (*Atropa bella donna.*) The deadly nightshade: it is an acro-narcotic poison. The name bella donna (*handsome lady*) is said to have been given from its having been used to improve the complexion. It contains the alkaloid *atropia*.

BELLE'ROPHON. (Gr. βελλεροφοντης; called also Hipponous.) In the fabulous history of Argos, the son of Glaucus, and grandson of Sisyphus (*Paus.* 2. 4.), who was obliged to flee from Corinth for the murder of Bellerus, and seek refuge at the court of Proetus. There Antæa, the wife of Proetus, conceived a violent attachment for him, which he requited as Joseph did the advances of Potiphar's wife. Nor does the analogy between the cases end here; for Antæa forthwith accused him to her husband of attempts on her virtue. Proetus, however, unwilling to violate the laws of hospitality, sent him to Tobates, king of Lycia, his wife's father, with a letter desiring him to put Bellerophon to death, and mentioning the cause. (Hence, a letter unfavourable to the bearer was called "Literæ Bellerophontis.") With this view, Tobates sent him on various perilous expeditions: first, against the Chimaera, a dreadful monster, which continually vomited flames (*Lucre.* v. 902.; *Virg. Æn.* vi. 288. vii. 785.), and which at that time devastated the country of Lycia, having the head of a lion, the middle of a goat, and the tail of a serpent. (*Ovid. Met.* ix. 646.) This monster, however, Bellerophon succeeded in destroying by the aid of a winged horse called Pegasus (*see* PEGASUS), which he had caught while drinking at the fountain Pirene in Corinth. In his next expeditions against the Solymi and the Amazons, he was equally successful (*Hom. Il.* vi. 155.), and consequently obtained the forgiveness of Tobates. Elated by his success, Bellerophon tried to fly to heaven on Pegasus; but Jupiter, enraged at his presumption, frustrated his attempts by sending an insect (œstrum) which stung the horse so violently that he became restive and threw his rider. Though maimed and shattered by the fall, Bellerophon was not killed; but he never perfectly recovered, and continued during the rest of his life to wander up and down in sorrow and dejection. (*Hom. Il.* vi. 201.) Bellerophon, we may add, was celebrated for his skill in horsemanship (*Hor.* Od. iii. 12. 7.), and is said to have first taught the art of riding. (*Plin.* iv. 56.)

BELLE'ROPHON. A fossil shell, the animal of which was probably allied to that of *argonauta*. The genus belongs to the carboniferous and older strata.

BELLES-LETTRES. (Fr.) Polite Literature. Almost all authors concur in censuring the vague and indefinite character of this term, as at one time every branch of knowledge has been included under this denomination, at another, excluded from it. Sometimes we are told that by the belles-lettres is meant a knowledge of the arts of oratory and poetry; sometimes that the true belles-lettres include natural philosophy,

geometry, and other essential parts of learning; and one author, in treating of the belles-lettres, introduces a discourse on the seven sacraments of the Romish church. In the division of the departments at the Lyceum of Arts, established at Paris in 1792, the belles-lettres comprehended general grammar, languages, rhetoric, geography, history, antiquities, and numismatics; whilst philosophy and the various branches of the mathematics were called, in contradistinction, sciences. Rollin and Rosenstein, who professedly treat of the belles-lettres, comprehend under the term all those instructive and pleasing branches of knowledge which chiefly occupy the memory and the understanding, and do not form part either of the superior sciences or of the mechanical professions. Belles-lettres, says Blair (after pointing out the tendencies of logical and ethical disquisitions), consider man as a being endowed with those powers of taste and imagination which were intended to embellish his mind, and to supply him with rational and useful entertainment. All that relates to beauty, harmony, grandeur, and elegance — all that can soothe the mind, gratify the fancy, or move the affections, belongs to their province. In an inquiry of this kind, reference must necessarily be made to Hume, who, both from the nature of his pursuits and the bent of his mind, was well qualified to give an opinion. Paraphrasing the well-known passage of a classic author, —

> Ingenuas didicisse fideliter artes
> Emollit mores, nec sinit esse feros, —

he asserts, that the belles-lettres improve our sensibility for all the tender and agreeable passions, at the same time that they render the mind incapable of the rougher and more boisterous emotions. Still the difficulty is not removed; for while all those writers concur in awarding a distinguished place in the category of learning to the "ingenuæ artes," the "literæ humaniores," as the belles-lettres are called, they have, if not thrown a veil of obscurity over the precise definition of the term, at least not condescended to remove it. If we have recourse to the Germans, we shall find that they comprehend under the denomination belles-lettres every branch of learning that is not cultivated with an ulterior view to pecuniary emolument; but their adoption of the term *belletristic*, to express all that relates to works of taste or æsthetics, does not appear to coincide with the definition above given by their professed lexicographers.

But though it would appear difficult to reduce this term within the limits of a precise and accurate definition, there can be little doubt that there are few terms which present so distinct a meaning to each individual mind. The influence of the belles-lettres has been felt and acknowledged in all ages. The beautiful tribute paid to them by Cicero in his defence of Archias is familiar to all. But we shall advert to the sentiments of another Roman, with whom we are more likely to sympathise, as he at least cannot be charged with special pleading. In the beautiful letter to Mæcenas, who was afflicted with some mental distemper, Horace first advises his friend to have recourse to the study of polite literature in particular, —

> Sunt *verba* et *voces* quibus hunc lenire dolorem
> Possis, et magnam morbi deponere partem;

and then concludes in these general terms, —

> Invidus, iracundus, iners, vinosus, amator,
> Nemo adeo ferus est, ut non mitescere possit,
> Si modo culturæ patientem commodet aurem.

But the high importance with which the same accomplished author has invested polite literature may be still better perceived in another of his epistles, —

> Trojani belli scriptorem . . . . .
> . . . . Præneste relegi,
> Qui, quid sit pulchrum, quid turpe, quid utile, quid non
> Planius et melius Chrysippo et Crantore dicit.

In this passage Horace pronounces Homer to be the most instructive teacher of moral and political philosophy; and indeed the tribute of respect which all the European nations pay to the Greeks in general, and to Homer in particular, as the authors of their refinement, sufficiently corroborates the opinion of the poet.

It would greatly exceed our limits to give even a cursory view of the belles-lettres in the decline and fall of the Roman empire; but we refer the reader to *Schlegel's History of Literature*, and to *Hallam's Introduction*, &c., for full information on this head. It may, however, be remarked, that during the long period of the middle ages (which has been often, though erroneously, considered as a blank in the history of the human mind) learning was almost wholly confined to the church; and though there was little original genius displayed in the province of imagination, yet here was preserved the germ of the future polite literature of Europe. As early as the 14th century, the spirit of polite literature, that had long been slumbering, was reanimated by the genius of Petrarch, and burst forth like a meteor in the Italian republics. Its genial influence was soon felt on this side the Alps; and in the year 1400, as Mr. Hallam observes, Spain, France, England, and Germany were in possession of a national literature. The traces of this spirit, however, were soon obliterated, and its effects gradually swallowed up in the wars that everywhere ensued, and in the all-absorbing taste for metaphysical and theological disquisitions that subsequently prevailed.

It is to the Reformation that may properly be ascribed the origin of polite literature in modern times; though, to use the words of Schlegel, the authors of that mighty spiritual revolution probably contemplated no other result from it than the emancipation of Europe from ecclesiastical bondage. Among the first-fruits of its effects upon the interests of the belles-lettres in England, it may suffice to mention the names of Spenser, Shakspeare, Dryden, and Milton, who have embodied in their writings all the riches of the English language, and whose works are of themselves sufficient to furnish any nation with a polite literature of which it might justly be proud. In France, too, shortly afterwards, literature assumed a novel and substantial form; and in the age of Louis XIV. there arose a mighty host of literary stars, which were only equalled in brilliancy by a contemporaneous galaxy of British genius.

The close of the last and the dawn of the present century may be regarded as an era in the history of polite literature throughout Europe. Never at any former period were the true nature and object, the wide extent and dignity, of the belles-lettres so universally appreciated. While, on the Continent, Göethe and Schiller were scattering from their rich and inexhaustible stores "thoughts that breathe, and words that burn," England could at the same time boast of the brilliant productions of the Great Unknown, whose influence on polite literature has been well compared to that of the bright luminary on the terrestrial globe. The rapid strides, too, that have been made in the art of criticism, the establishment of reviews in every country on a more comprehensive plan than was ever previously adopted, and the general ability with which these are executed, have greatly contributed to the formation and confirmation of a literary taste. In his admirable Essay on the Rise of the Arts and Sciences, Hume has remarked, that nothing is more favourable to the rise of politeness and learning than a number of neighbouring and independent states connected together by commerce and policy. Now, if we apply this observation to the various classes of society in the same country, and contrast the present state of society with that which existed even in the time of Hume, we may perhaps find another clue to the wide spread and cultivation of polite literature among us. At no very distant period, a broad line of demarcation was drawn between the literary and commercial classes of the community; in fact, literature and commerce stood separated like two different worlds revolving in different spheres. But the scene is changed; the framework of society has become more artificial and complicated; and we may now see the learning of the philosopher, the acuteness and promptitude of the man of business, and the earnestness and enthusiasm of the solitary artist, all brought into actual contact, and shedding each its influence upon the rest. *Schlegel's History of Literature.* (*See* art. LITERATURE in this work, and the authorities there referred to.)

BELL METAL. An alloy of 80 parts of copper and 20 of tin. The Indian gong metal is a similar alloy. An English bell metal analysed by Dr. Thomson was found to consist of 800 copper, 101 tin, 56 zinc, and 43 lead. Small shrill bells generally contain zinc.

BELLO'NA. (Lat. bellum.) In the mythology of the ancients, was the wife or sister or the sister wife of Mars, and was especially worshipped by the Romans as the goddess of war. She possessed a temple, built and dedicated to her by Appius Claudius, which stood in the Circus Flaminius, near the Porta Carmentalis. It was here that the senate granted audiences to foreign ambassadors, and received generals on their return from abroad. In front of this temple also stood the pillar against which the javelin was hurled, the usual preliminary among the Romans to a declaration of war. Bellona is generally depicted as the charioteer of Mars, with wild dishevelled hair, bloody garments, and a torch in her hand. Though the Romans were her chief worshippers, there were many temples dedicated to her service in Cappadocia and Paphlagonia. The priests of this goddess, who were termed *Bellonarii*, consecrated themselves by incisions in their bodies, and sacrificed to her honour the blood which flowed from their wounds.

BE'LLOWS. A machine contrived to propel air through a tube or orifice. It is used for blowing fires, supplying the pipes of organs, and other purposes, and is constructed according to various forms, but the principle is the same in all of them. The dimensions of a space in which air is confined are contracted; the air, being permitted to escape only at a small opening, rushes out

with a velocity proportional to the pressure and to the smallness of the opening.

BE'LLUÆ. (Lat. bellua, *any great beast.*) The term by which Linnæus designated an order of Mammalia, nearly corresponding to the Pachyderms of Cuvier.

BE'LOMANCY. (Gr. βελος, *javelin*, and μαντεια, *prophecy.*) Divination by the flight of arrows, common to various oriental nations, and especially observed by the Arabians. It has been performed in various modes; one of the most common is, to let fly arrows, with inscriptions on labels attached to them, and take for a guide the contents of that belonging to the arrow first found.

BEL'TANE, or BE'LTIN. (Said to be the "fire of Bel" or Belus.) May-day, and the traditional Celtic customs attached to it. The month of May is thus called in the present Irish language. This day is particularly celebrated by the herdsmen in the Highlands of Scotland. The Beltane-fire, Beltane-cake, &c., are all observances of this day.

BELTS. A name given to the zones or bands which appear on the disk of the planet Jupiter. They are situated near and parallel to the equator of the planet, and are supposed to be produced by clouds in its atmosphere arranged in parallel strata, by currents of wind, which, by reason of the rapid rotation of the planet, must in the equatorial regions blow always in the same direction.

BELVEDE'RE. (It. *a fine prospect.*) In Architecture, a small building at the top of a house or palace, constructed, as the name implies, to obtain a view of the country.

BELVISI'EÆ. (Belvisia, one of the genera.) In Botany, a natural order of monopetalous Exogens, inhabiting Africa on the west side. Scarcely anything is known of the species, and its affinities are quite unsettled. One of the species was called *Napoleona imperialis* by its discoverer, Palisot de Beauvois, after whom the genus typical of the order is now named.

BE'MBEX. A genus of Hymenopterous aculeate insects of the tribe *Fossores*, or burrowing sand-wasps; raised by Dr. Leech to the rank of a family (*Bembecidæ*), and including the genera *Bembex* proper, *Monedula*, and *Stizus*. Head transverse, with the upper lip exposed; tongue long, legs short; the brachia of the female furnished at the sides with very strong spines for burrowing in the sand. For the habits of this family, *see* Fossores.

BEMBI'DIUM. A name applied by Latreille to a genus of Coleopterous insects, of the tribe *Carabidæ*. Now raised to the rank of a family (*Bembidiidæ*), including the genera *Lymneum* 1, *Cillenum* 1, *Tachys* 8, *Philochthus* 6, *Ocys* 3, *Peryphus* 16, *Notaphus* 9, *Sopha* 11, *Tachypus* 9, *Bembidium* proper 4: the figures refer to the number of indigenous species in each of the genera. The common characters of the group are, cubits notched, elytra rounded at the extremity, abdomen not pedicellate, external maxillary palpi terminated by a very minute and acute joint, antennæ sub-elongate. The *Bembidiidæ* are generally found in low and damp situations, are of very small size, and glitter with polished metallic colours.

BEND. In Heraldry, an ordinary bounded by parallel lines, equally distant from the line joining the dexter base to the sinister chief. It contains the fifth part of the escutcheon if charged, and the third if not charged. The bend sinister, descending from the sinister chief to the dexter base, is the well-known difference which denotes bastardy, being borne on the paternal escutcheon of the bastard.

To Bend. The general sea term for fastening any thing; as to bend one rope to another, the cable to the anchor, a sail to a yard or gaff. Certain knots are called *bends;* as a carrick bend, a fisherman's bend, &c.

BENDS, called also WALES. A certain number of thick planks of the ship's side, from the water upwards.

BENEDI'CTINE MONKS. An order of monks that followed the rule of St. Benedict, which, as early as the 6th century, had extended itself through Italy, France, Spain, Germany, and England. The rules of Benedict, although founded no doubt on the old monastic institutions of Cassian (*Cassiani Opera*, Lips. 1733), were of a much more rational and comprehensive character. Avoiding the extreme rigour of the Eastern systems, he not only exacted a promise from all who entered a convent that they would remain for life, and strictly observe its rules (*Marten. Commen. in Regulas Bened.* Paris, 1690), but prescribed to them a variety of suitable employments. This system soon made rapid progress, and the monks began to be useful to society in various ways: reclaiming waste lands, promoting zealously the cause of education, preserving the history of the times in their chronicles, and multiplying the treasures of antiquity by their copyists. Under Charles the Great this order of monks was preferred to every other; and the spirit of inquiry which they then called into existence was perpetuated by the depth of their enthusiasm and the extent of their learning. To give even a cursory history of this order would far exceed our limits, as it embraces perhaps the palmiest days of ecclesiastical domination. (Vide *Gieseler's Kirchen-geschichte;* a work of great learning, and, as a book of reference, incomparable.) As is universally known, it is to the Benedictine monks that England (A. D. 596) is indebted for its conversion from idolatry. This order has produced a vast number of ancient writers and men of learning. Among others, Placidius Maurus founded the school of Germany; Alcuinus the university of Paris; Guido invented the scale of music; Dionysius Exiguus completed the collection of papal decrees (A. D. 510); and the most learned man of his time, the admiration of the whole Western world, the Venerable Bede, belonged to this order.

BE'NEFICE. (Lat. beneficium.) A word denoting a certain class of church preferments, viz. rectories, vicarages, perpetual curacies, and chaplaincies; and distinguished from a dignity, under which title are comprehended bishoprics, deaneries, and prebends. Under the Romans, certain grants of lands made to the veteran soldiers were called beneficia; and the same term was applied at the commencement of the feudal system to estates conferred by the sovereign and held under him: which afterwards assuming a hereditary character became "fiefs" properly so called. In the middle ages the popes assumed the feudal right with reference to ecclesiastical "patronage," and the term beneficium was hence applied to livings, &c., on the assumption that they were held under the pope as a superior lord. It was the assertion of this claim by Innocent III. and his successors which roused the jealousy of the European sovereigns, especially those of England and France; and from the contentions consequent upon this the first opening was made to the cause of Reformation.

BE'NEFIT OF CLERGY. In Law, originated in the immunities from municipal jurisdiction enjoyed in many states of Europe by the Roman Catholic clergy during the middle ages. When a person indicted for certain offences (most of those subjecting the offender to capital or corporeal punishment, excepting high treason) pleaded that he was a clerk or clergyman, and claimed privilege, he was demanded by his ordinary: a jury was summoned, and he was tried; and, according to their verdict, delivered to the ordinary as acquit or convict, to undergo canonical purgation, and to be discharged or punished according to the result of such purgation. The proof of clergy, at first strictly required, was at last so relaxed, that it was only necessary for the offender to show that he was able to read. The bishop's commissary was present, to decide whether or not he passed the test satisfactorily. This loose mode of acquiring the privilege was first restricted by the stat. 4 H. 7. c. 13., which provided that offenders who had been allowed their clergy should be "burnt in the thumb," and if they claimed it a second time, be required to give proof of being actually in orders. By 18 Eliz. c. 7., the second trial by compurgation before the ordinary (which had become a mere fiction) was abolished, and the judges were empowered to imprison the person who had benefit of clergy for a year, if they thought proper. By various subsequent statutes, the burning in the hand was commuted for transportation, whipping, &c., at the discretion of the judges; and the benefit was taken away altogether from a number of statutable felonies. By 5 Anne, c. 6., the ceremony of reading was abolished, benefit of clergy being granted indiscriminately to all entitled to it; and finally by one of the enactments commonly called Peel's Acts (7 & 8 G. 4. c. 28. s. 6) benefit of clergy was abolished altogether.

BENE'VOLENCE. (Lat.) In English History, a species of tax levied by the sovereign. As its name implies, it was nominally a gratuity; but was, in point of fact, exacted as a forced loan, with or without the condition of repayment, under the reigns of the Plantagenet kings. By a statute of Richard III. benevolences were declared illegal; but they were again exacted by Henry VII., and occasionally, by means of circulars under the privy seal, by his successors. By 13 C. 2. stat. 1. c. 4. no voluntary aid can be raised on behalf of the king without the authority of parliament; and the general illegality of levying money for the use of the crown without such authority was declared in 1688 by the Bill of Rights.

BEN NUTS. The seeds of an Arabian plant called *Moringa aptera;* they yield an oil, called oil of ben, and have been employed in syphilitic diseases.

BEN, OIL OF. The expressed oil of the nut of the *Moringa aptera.* This oil is remarkable for not becoming rancid by age; and as it is perfectly insipid and inodorous, it is used for extracting the fragrancy of certain flowers, such as jessamin, orange, &c. The same tree furnishes the *Lignun nephriticum*, supposed to be useful in certain affections of the kidneys.

BENT GRASS. A species of Agrostis, the bent and creeping stems of which are very difficult to eradicate.

BENTS. The withered stalks of grass standing in a pasture after the seeds have dropped.

BE'NZAMIDE. A compound, obtained by exposing chloride of benzule to ammoniacal gas.

BENZO'IC ACID. This acid forms a constituent of many balsams; it is generally obtained by heating benzoin, and collecting the acid vapours which are evolved and condense in brilliant acicular crystals. It is a compound of carbon, hydrogen, and oxygen; its equivalent being 120. Its combinations are called *Benzoates*.

BENZO'IN. The resinous exudation of the *Styrax benzoe*, a tree which is a native of Sumatra. Benzoin is a combination of resin and *benzoic acid*. It has a mottled or amygdaloid texture, and is composed of a mixture of brown and white parts. It has a fragrant odour.

BENZULE. (From benzoin, and ὕλη, *principle*.) A compound of carbon, hydrogen, and oxygen, regarded as the base of benzoic acid.

BERBERA'CEÆ, or BERBERIDEÆ. A natural order of plants, named after the genus Berberis, which is in fact the most important genus it contains. It is the only one whose fruit is succulent and eatable; that of the others is dry and hard.

BE'RBEREN. A yellow bitter principle, contained in the alcoholic extract of the root of the barberry tree.

BE'RBERRY. (Lat. berberis.) A spiny shrubby plant, bearing yellow flowers, and succulent one-celled fruit growing in racemes. It is one of a genus in which the fruit is universally fleshy and acid, although often less so than in the common kind (*Berberis vulgaris*). Some of the species have pinnated leaves, many are evergreens, and several have a black fruit; even the common sort has a variety of this description, as well as others with pale yellow and stoneless fruit. There is an idea among people in the country that a berberry bush brings blight to a wheat field; but the parasitical fungus which attacks the berberry is altogether different from that which produces the mildew of wheat, which cannot possibly be communicated by the one to the other.

BE'RGAMOT, ESSENCE OF. The essential oil of the rind of a small pear-shaped fruit, the produce of the *Citrus limetta bergamium*. It is much used as a perfume, and apt to be adulterated with the oils of orange and lemon peel, and with alcohol.

BERO'SUS. In Entomology, a genus of Coleopterous insects of the family *Hydrophilidæ*. They inhabit ponds, in which they may often be seen swimming in an inverted position.

BE'RYL. A mineral allied to the emerald, composed of 68 silica, 15 alumina, 14 glucine, 2 lime, 1 oxide of iron. It is usually transparent, pale green, and in beautiful crystals, much larger than those of the emerald. It is the *aquamarine* of the jewellers. The finest comes from Dauria, on the frontiers of China, from Siberia, and from Brazil.

BESI'MEN. An obsolete term for the spores or seeds of the lowest kinds of plants, especially of Algæ.

BE'TEL. The leaf of the betel or Siriboa pepper, which is chewed by the inhabitants of many parts of India along with a nut of the areca palm tree and lime; which substances are wrapped in the betel leaf. It is acrid and narcotic, and stains the saliva red.

BETHY'LUS. In Entomology, a genus of Hymenopterous insects of the family *Proctotrupidæ*.

BETRO'THMENT. A mutual compact between two parties, by which they bind themselves to marry. Betrothment was a legal contract by the Roman law, as it now is in that of various continental countries. In Germany, betrothments are either public, with the consent of relations and presence of witnesses; or private (clandestine), which in some countries are void, in others, although valid as contracts, punishable as misdemeanors. Public betrothment induces the obligation to marry. But according to modern practice an action for damages is almost the only way of enforcing it; a small fine or imprisonment being the utmost criminal penalty for the violation of the engagement.

BETULA'CEÆ. (Betula, one of the genera.) A small natural order of plants, containing the birch, after which it takes its name, and the common alder. The order formed part of what were formerly called *Amentaceæ*.

BE'VEL. (Lat. bivium, *branching road*.) In Architecture, an instrument for taking angles. One side of a solid body is said to be bevelled with respect to another when the angle contained between their two sides is greater or less than a right angle.

BEVEL ANGLE. A term used among artificers to denote an angle which is neither a right angle nor half a right angle.

BEVEL GEER. In Mechanics, a species of wheelwork, in which the axles of two wheels working into each other are neither parallel nor perpendicular, but inclined to one another in a certain angle. Wheels of this kind are also called conical wheels, because their teeth may be regarded as cut in the frustrum of a cone. *See* WHEEL.

BEY, or BEG. A Turkish and Tartar title of dignity, used with no very accurate application for lord, prince, or chief, and frequently subjoined to the proper names of persons of rank.

BEZA'NT. A gold coin struck at Byzantium (Constantinople): they varied in weight and in value. Bezants appear to have been current in England from the tenth century to the time of Edward III. Some of them weighed about twenty grains. According to Camden, a piece of gold which was anciently offered by the king on high festivals was called a *bizantine*, and valued at 15*l*. There were also white or silver bezants.

BEZANT. In Heraldry, a circle, or. The name is derived from the gold coins of the Greek empire, termed bezants, or byzantines, by the people of the West. It was probably introduced into coat armour by the Crusaders.

BE'ZOAR. A Persian word implying destructive of poison, and applied to certain intestinal concretions of animals, called bezoar stones, and supposed to possess such powers.

BI. (Lat. bis, *twice*.) Signifies, when attached to other words, two, twice, or double; as bicarbonate of potash, a compound of potash with two atoms of carbonic acid; bilocular, two cells; bivalve, two valves, &c.

BIARTI'CULATE. (Lat. bis, articulus, *joint*.) Applied in entomology to the antennæ of insects when they consist but of two joints, and also to the abdomen under the same circumstances, as in the *Nycteribia biarticulata*.

BIAURI'CULATE. (Lat. bis, auricula, *an auricle*.) In Comparative Anatomy, signifies a heart with two auricles, as in most bivalve molluscs, and in all reptiles, birds, and mammals.

BI'BLE. (Gr. βίβλος, *a book*; from whence the word came to be applied emphatically to the volume of the Old and New Testaments.)

The sixth article of the English Church enumerates the books of the Old Testament, which it considers of canonical authority; in which it follows the canon received by the Jews in the time of our Saviour. The apocryphal writings, which are accounted authentic by the Roman Catholics, are of undoubted antiquity, being comprised in the Septuagint edition of the Scriptures; but their authority has never been acknowledged by the Jews, who reckon twenty-four canonical books; nor are their originals found in the Hebrew language.

The canon of the New Testament is now received without variation, we believe, in all Christian communities. In the early period of the church, the authenticity of particular books was frequently disputed, and heretical sects attempted to foist other apocryphal writings into their place. The general consent, however, of the orthodox church may be inferred from catalogues extant in the writings of many of the Fathers throughout the first four centuries, and the express declaration of the council of Laodicca and others. Some latitude of opinion seems, however, to have been allowed in early times respecting the book of Revelations; and some of the Fathers confess that the genuineness of St. Paul's Epistle to the Hebrews, of that of James, of the second of Peter, and two last of John, was held by some to be undecided.

BIBLE SOCIETY, THE BRITISH AND FOREIGN. A society established in England in the year 1804, "with the sole object," as it is expressed in its regulations, "of encouraging a wider circulation of the Holy Scriptures without *note or comment*." The society took its rise from the circumstance of the complaints which had been made in Wales for some years previous, respecting the great deficiency of Bibles in the language of the Principality — a want which, it was urged, the Society for Promoting Christian Knowledge had very imperfectly supplied. The earliest promoters of this institution were the Rev. Mr. Charles of Bala, Mr. Hughes, and Mr. Steinkoff, minister of the German Lutheran Church. Among its principal patrons may be mentioned Lords Teignmouth and Gambier, Messrs. Wilberforce, Granville Sharp, and Charles Grant. This society has now auxiliary establishments connected with it not only in all the principal cities of the United Kingdom, but throughout Europe and North America.

The principle upon which the Bible Society acts has always been regarded with jealousy by the high church party in this country. In the first place, it is looked upon not only as a rival to the venerable Society for Promoting Christian Knowledge, which had been in action since the year 1699; but as casting some slur upon the latter as inefficient in its operation and erroneous in its principles. The younger society also admits as members the adherents of every religious denomination, and in its proceedings maintains an absolute neutrality among them — which its opponents consider incompatible with the profession of true churchmanship. Accordingly many controversies have been carried on between the champions of the two institutions: in the course of which, however, it would seem that the Bible Society has gained ground in the favour of the established church, from whence a large proportion of its subscribers are now derived. Among them are the names of several bishops, and many other dignitaries.

In the report for 1840, we find the total number of

Bibles and Testaments issued by this society since its foundation to be 12,322,471. The number issued during the year ending March, 1840, was 776,360. The income of the society for that year was 111,449*l*. 13*s*. 1*d*.

BI'BLICAL HISTORY and LITERATURE. The accounts of the books of the Jewish Scriptures antecedent to the captivity are few and indistinct; but they are referred to under the titles of "the law," "the books of Moses," and "the books of the law of Moses," by Daniel (ix. 11.), Ezra (vi. 18.), and Nehemiah (viii. 1.): there are also other passages from which it may be inferred, independent of the internal evidence of the books which we possess, that there existed such from an early period.

The canon of the Old Testament appears, however, to have been settled, and the limits of inspired Scripture determined about 50 years after the return from the captivity, by the authority of Ezra and the prophets of his day; the books of Nehemiah, Malachi, and Ezra himself being subsequently added. The sacred writings which came in later times to be incorporated in the collection of the Jewish Scriptures are known by the name of Apocrypha, or secret: they were undoubtedly held in respect by the Jews, and by the Christians afterwards; but Protestants deny that they were ever held to be inspired, or their authority placed on the same footing as that of the canonical Scriptures.

At a later period we find passages in the New Testament, in Philo, and most distinctly in Josephus, to prove the fact of this collection of the Scriptures into a volume. The books themselves are first specified by Origen, who enumerates twenty-two, in which number he coincides with Josephus. His list embraces all that we consider canonical, and rejects the Apocrypha.

The early versions which illustrate the question of the antiquity of the Hebrew Scriptures are the Samaritan Pentateuch, and the Septuagint or Greek translation. It is not to be supposed that the Samaritans would have adopted and translated the books of the Jews, unless they had been received prior to the separation and enmity of the two peoples, the period at latest of the return from the captivity. The Samaritan Pentateuch now extant is said to be a version from the earlier Hebrew Samaritan into the more modern Samaritan, and was made before the time of Origen. The part of the Septuagint which comprises the Pentateuch was made about the year B. C. 285; the translation of the other book into Hellenistic Greek appears to be of different and somewhat later dates.

Next in order to these may be mentioned the versions of the Old Testament in the earliest periods of Christianity, which are important, not as assisting us to ascertain the antiquity of the original, but as contributing to our knowledge of the genuine text. These may be divided into three classes.

I The Oriental, comprising—
- The Syriac or Peschito (literal), from the Hebrew, about the end of the first century—embracing both the Old and New Testaments.
- The Coptic, from the Septuagint—between centuries two and five. This embraces also the New Testament.
- The Ethiopic, from the Septuagint—in the fourth century: embraces the N. T.

II. The Latin, or Western:—
- The Italic, from the Septuagint, in either the first or second century; only fragments remain: it embraced also the New Testament.
- The Vulgate, made from the Hebrew by Jerome, A. D. 390. This translation is considered an ultimate authority by the church of Rome.
- The Gothic version of Ulphilas, which was made from the Greek of both the Old and New Testaments, in the fourth century, has not come down to us entire. Only a small part is in print.

III. The Greek, comprising—
- The version of Aquila.
- —— of Theodotian.
- —— of Symmachus.

All translated from the Hebrew; all of or near the second century; all exist only in the fragments of the Hexaple or combination of six versions by Origen.

The genuineness of the Hebrew text was preserved after the destruction of Jerusalem by the sedulous care of learned academies which flourished at Tiberias, Babylon, and other places, from the first to the twelfth centuries. The date of the Masora is generally fixed about the fifth century. This work consisted of a most minute enumeration of the sections, verses, words, and letters of the Scriptures; which has been so successful in fixing the genuine reading, that although there were discovered upwards of 800 discrepancies between the Oriental and Occidental Recensions, they all relate, with one single exception, to vowel points, and are of no kind of importance. For an account of the labours of the early Jewish schools of criticism in the interpretation of the Hebrew text, *see* art. TALMUD.

The integrity of the text of the New Testament has been established by the collation, wholly or in part, of 674 manuscripts, existing either entire or in fragments. These have been classified by modern critics according to recensions or families, the most simple of whose systems and that most approved, is Scholz's, who considers all the variations that exist in these MSS. to be resolvable into their having been transcribed from Constantinopolitan or Alexandrian exemplars. The former he considers to have been from the earliest times the most strict and faithful recension. It was that which was principally used in the liturgical offices of the East; and its fidelity is argued from the exact uniformity of all the MSS. which can be traced historically to a Constantinopolitan origin. This may be accounted for by the authority inherent in the text received in the centre of the imperial power and of the patriarchal jurisdiction. It is also consistent with the minute care with which the rites of the Constantinopolitan church were enjoined by its missionaries upon their converts; and also with the character of the Greek fathers, who present much greater exactness and uniformity in their quotations of the New Testament than the African. On the other hand, the Alexandrian copies have been written with a considerable degree of carelessness, and do not appear to have been intended, even in their own country, for reading in public service. They are said to partake in the rash and speculative spirit of the theologians of the Alexandrian church. The former of these recensions has been adopted in the Syriac, Gothic, and Sclavonic versions. It is that also which forms the basis of our modern texts. The latter was followed by several Latin, the Coptic, and Ethiopic translations. Erasmus conceived the idea of the Greek text having been purposely corrupted to suit the Vulgate, and assigns the council of Florence in 1439 as the authority by which this transaction was effected. This opinion continued to be held under the title of the Fœdus cum Græcis, with more or less discussion till modern times, by which it seems to be very generally rejected as untenable. It is known, on the contrary, that in the compilation of his translation, which bears the name of the Vulgate, the existing Latin version was corrected by Jerome from the Greek.

BIBLIO'GRAPHY. (Gr. *βίβλιον*, *a book*, and *γραφω*, *I describe*.) The science of books. The knowledge which is required to classify books, according to the various subjects on which they treat, has been termed intellectual bibliography; that of the external peculiarities of books, their editions, &c., material bibliography. The first branch borders closely on the province of criticism; for the most valuable bibliographical works, being what are termed in French "catalogues raisonnées," are those in which the lists of books are accompanied with some remarks on the character of their contents. The second branch of bibliography has been of late years cultivated with all the ardour attached to a fashionable and somewhat eccentric pursuit. The lovers of rare editions and curious copies of works, from being, to borrow a French term, "bibliophiles," have formed of late a peculiar sect entitled "bibliomaniacs," with whom the fancy for books has become a passion, like those of Dutch speculators for tulips and pictures. Many works of novel and curious research in this department of literature have been recently produced to guide their taste, and gratify their appetite. For the purposes of the common student, *Brunet's Manuel du Libraire*, although by no means complete, is still the most useful index to general literature. Many books of a similar character exist in English, but none that can be recommended as generally valuable; although some of those devoted to particular branches of the subject, especially to the learning of early editions, display much curious research. *Watt's Bibliotheca Britannica*, although useful, from its double arrangement according to subjects and authors, is a very imperfect work.

The following list contains a selection from among the most valuable works which we possess, in different departments of bibliography. But many of them, from the critical matter which they contain, may be considered to belong to the history of literature, as well as of books and editions.

I. ***Introductory Works on the Science of Bibliography.***
- *Peignot*, Manuel Bibliographique, 1800.
- *Peignot*, Dictionnaire Raisonné de Bibliologie, 3 vols. 8vo.
- *Achard*, Cours de Bibliographie, 3 vols. 8vo. Marseilles, 1807.
- *Horne, Thomas Hartwell*, Introduction to the Study of Bibliography, 2 vols. 8vo. Lond. 1814.
- *Denis*, Einleitung zur Bücherkunde, 2 vols. 4to. Vienna, 1796.
- *Boulard*, Traité Elementaire de Bibliographie.

II. ***Bibliography of the Oriental and Classical Languages.***
- *Clarke*, *Dr. Adam*, Bibliographical Dictionary and Miscellany, 8 vols. 12mo. Lond. 1802-6.

Le Long, Bibliotheca Sacra, 2 vols. fol. Paris, 1723.
Fabricius, Bibliotheca Græca, edited by Harles, 12 tom. 4to. Hamburg, 1790. 1809.
Fabricius, Bibliotheca Latina. By Ernesti. 3 vols. 8vo. 1773-74.
Fabricius, Mediæ et Infimæ Ætatis. By Manso. 3 vols. 4to. Patav. 1759.
Harwood's View of the various Editions of the Greek and Roman Classics, 1775.
Dibdin's Introduction to the Knowledge of rare and valuable Editions of the Classics, 2 vols. 8vo. 1827 (last edition).
Moss's Manual of Classical Bibliography, 2 vols. 8vo. 1825.
Degli Autori Classici Biblioteca Portabile (Boni and Gamba), 2 vols. 12mo. Venice, 1793.

III. *Bibliography of particular Sciences and Branches of Literature.*

Lipenius, Bibliothecæ (Theologica, Juridica, Philosophica, Medica), 6 vols. fol. The Juridica by itself has been reprinted, with supplements, &c. in 4 vols. Leipsic, 1775-89. The whole collection passes under the title of Bibliotheca Realis.
Meusel, Bibliotheca Historica.
Bibliotheque Historique de la France, 5 vols. folio, 1768, 1778.
Bridgman's Legal Bibliography, 8vo. Lond. 1807.
Murhard, Bibliotheca Mathematica.
Dryander, Catalogus Bibliothecæ Historiæ Naturalis Josephi Banks (a general account of books on natural history).
Lalande, Bibliotheque Astronomique, 4to. Paris, 1803.
Boucher de la Richarderie, Bibliotheque de Voyages. 6 vols. 8vo. Paris, 1808.

IV. *Bibliography of Modern Nations.*

Watt's Bibliotheca Britannica, 4 vols. 4to. Edin. 1819. This very laborious work contains a mere catalogue of works, arranged alphabetically, first under the head of writers, and then of subjects. A more complete, and more critical work on English Bibliography, is among the greatest desiderata of the present day. Dr. Watt's work contains many foreign articles; but is chiefly devoted to English literature.
Querard, La France Littéraire; a very valuable catalogue of French works, in all departments of literature. Paris, 1828.
Mazzuchelli, Autori d'Italia; a work containing literary history and biography, with bibliographical science. 2 t. fol. Brescia, 1753-63.
Foppen, Bibliotheca Belgica, 2 vols. 4to. 1739.

V. *Bibliographical Works on rare Books, Typographical Antiquities, early Editions, &c.*

Vogt, Catalogus Librorum Rariorum, 8vo. 1732.
Gerdesius, Florilegium Librorum Rariorum, 8vo. 1731.
Clement, Bibliothêque Curieuse, ou Catalogue Raisonné des Livres Rares, 4to. 1750-60. A minutely critical work.
Bauer, Bibliotheca Librorum Rariorum Universalis, 7 vols. 8vo. 1770-91.
Maittaire, Annales Typographici ab Artis inventæ Origine, 5 vols. 4to. Hamb. 1719-41. Several supplements have been published.
Panzer, Annales Typographici ab Artis inventæ Origine ad Annum 1500. (It is, however, carried down to 1536.) 11 vols. 4to. Nuremb. 1793. 1803.
Ames's Typographical Antiquities, first edition, 1749; republished by Mr. Huhet in 3 vols. 4to. 1790; and again by Dr. Dibdin.
Dibdin, Bibliotheca Spenceriana (a catalogue of books in the Spencer library, printed before 1500), 4 vols. 8vo. 1814. Well known, like most of the other works of this distinguished bibliographer, for the minuteness of its research and extreme beauty of embellishment.
La Serna Santander. Dictionnaire Bibliographique Choisi du Quinzième Siècle, 3 vols. 8vo. 1805.
De Bure, Bibliographie Instructive, ou Traité de la Connaissance des Livres rares et singuliers, with supplements, in all 10 vols. 8vo. Paris, 1713, 1782. The most practically useful work on the subject.
Osmont, Dictionnaire des Livres rares, 2 vols. 8vo. Paris, 1768.
Raynouard, Historie de l' Imprimeur des Aldes. *See* ALDINE EDITIONS.

VI. *General Bibliographies, and Miscellaneous Works.*

Dictionnaire Bibliographique, 3 vols. 8vo. Paris, 1790.
Brunet, Manuel du Libraire, 3rd and enlarged edition. 4 vols. 8vo. 1820. A work of the greatest utility. Two supplementary volumes were published in 1832.
Morhof, Polyhistor Literarius, Philosophicus et Practicus, first edition by Fabricius, 2 vols. 4to. 1747.
Saxii Onomasticon Literarium, 8 vols. 4to. 1759. 1803.

BICA'LCARATE. (Lat. bis, calcar, *a spur*.) When a limb or part is armed with two spurs.

BICE. In Painting, a light blue colour prepared from smalt. From it, by a mixture with yellow orpiment, another colour is formed of a green hue, bearing the same name.

BI'CEPS. (Lat. bis, *twice*, and caput, *head*.) An anatomical term, applied to muscles having a double insertion, or which arise by two heads.

BICO'LLIGATE. (Lat. bis, *twice*, colligo, *I bind together*.) In Ornithology, a term signifying the connexion of all the anterior toes by a basal web.

BI'COLOR. (Lat. bis, color, *colour*.) When an animal or part is of two colours.

BICO'RNIS. (Lat. bis, cornu, *a horn*.) In Zoology, when an animal or part has two horns, or two horn-like processes. In Anatomy, when the uterus has two divisions, like horns, as in most quadrupeds.

BICU'SPIS. (Lat.) A tooth with two points.

BIDE'NTATE. (Lat. bis, dens, *a tooth*.) When an animal has but two teeth, as the *Delphinus bidens*; or when a part has two tooth-like processes.

BIE'NNIAL. (Biennis, *of two years' duration*.) A term applied to plants which grow one year and flower the next, after which they perish; they only differ from annuals in requiring a longer period to fruit in. Most biennials, if sown early in the spring, will flower in the autumn, and then perish, thus actually becoming annuals.

BIESTINGS. The name given to the first milk yielded by a cow after calving.

BIFA'RIOUS. (Lat.) Arranged in two rows.

BI'FORATE. (Lat. bis, foro, *I pierce*.) Having two perforations, as the anthers of a Rhododendron.

BI'FORINES. Singular bodies lately discovered in the interior of the green pulpy part of the leaves of some Araceous plants. They are minute oval sacs, tapering to each end, where they are perforated; they are apparently composed of two bags one within the other, the space between the bags being filled with a transparent fluid, and the inner bag itself with fine spiculæ. When the biforine is placed in water it discharges its spiculæ with considerable violence, first from one end, and then from another, recoiling at every discharge, and eventually emptying itself, when it becomes a flaccid motionless bag. Nothing is known of the nature, use, or origin of these bodies.

BIFU'RCATE. (Lat. bis, furca, *a fork*.) When a part has two prongs like a fork.

BI'GAMY. (Lat. bis, *twice*, and Gr. γαμος, *marriage*.) The offence of contracting a second marriage during the life of the husband or wife, which, by the law of England, is felony, punishable by transportation for seven years, or imprisonment for two. Bigamy, by the canon law, signified a second marriage after the death of the first wife, or a marriage with a widow; and incapacitated the party contracting. *See* MARRIAGE, LAW OF.

BIGHT. Part of a rope between the ends; bight is also a shallow bay or hollow in the line of sea coast.

BIGNONIA'CEÆ. (So called from Bignon, a French man of letters, and the friend of Tournefort.) A natural order of Didynamous plants, usually having a twining stem, large trumpet-shaped flowers, and a pod-like capsule with winged seeds. Some of them are trees of considerable size, and furnish timber valuable in the countries where it is produced; but the greater part are interesting only for the beauty of their flowers, in which respect this order yields to no other. *Bignonia venusta*, *Pandoræ*, *æquinoctialis*, *cherere*, and *grandiflora*, are probably the handsomest twining plants known.

BI'JUGATE. (Lat. bis and jugum, *a yoke*.) Composed of two pairs of any thing; a term applied to leaves pinnated with two pairs of leaflets.

BIKH. A deleterious plant inhabiting Nepal, and used by the natives of that country to poison their wells when the British troops invaded it. The *Aconitum ferox* has been ascertained to be this poison, which, like that of all other Ranunculaceous plants, is volatile; and although highly dangerous when fresh, soon loses its activity when exposed to the air.

BILA'BIATE. (Lat. bis and labium, *a lip*.) When a flower has all or any of its parts collected into two separate parcels or lips. Thus a calyx having two of its sepals collected into one parcel, and the others into a second parcel, or a corolla with its five petals adhering two and three together, are bilabiate.

BILAME'LLATE. (Lat. bis, lamella, *a plate*.) When a part is divided longitudinally into two lamellæ.

BI'LBERRY. A small bush inhabiting the northern parts of Europe in mountainous situations, and bearing small black berries, which are eaten by country people, and are a favourite food of deer. It is the *Vaccinium myrtillus* of Botanists.

BILDSTEIN. (German.) A mineral composed chiefly of silica and alumina, with a little oxide of iron. It is commonly seen carved into Chinese figures.

BILE. (Lat. bilis; said to be derived from bis, *twice*, and lis, *contention*, as being the supposed cause of anger and dispute.) A fluid secreted in the liver, of a yellow colour, and a nauseous taste, compounded of sweet and bitter; it sinks in water, and mixes with it in all proportions; it is slightly alkaline, and feels soapy. It contains a peculiar bitter principle, which has been called *picromel*, and a little free soda and saline matters. According to Berzelius, the solid constituents of bile amount to about one tenth of its weight.

BILGE. The lower or flat part of the bottom of a ship on which she rests when aground. — Bilge of a cask, the middle part between the ends, in which the bung-hole is placed.

BILGED. Having the bottom stove in.

BILGE WATER. The water that collects in the bottom, by leakage or otherwise. It has usually a peculiar and offensive smell. When a ship is tight the bilge water when pumped up is dark; in a leaky ship, it comes up quite clear.

BI'LIARY CALCULI. Are concretions which form in the gall-bladder (gall stones) or bile-ducts. They are generally composed of a peculiar crystalline fatty matter, which has been called *cholesterine*.

BILL. A legislative measure introduced into parliament is so called until it has acquired the force of law by receiving the royal assent. Bills are either public or private; a distinction founded rather on usage and precedent, than on any exact definition. The immediate parliamentary consequence of the distinction is the payment of certain fees to the officers of the house, which are due by custom on private bills. According to Hatsell, this difference between private and public bills was recognised as long ago as 1607. It is a general rule of parliamentary proceeding, that the same bill or question cannot be twice offered in the same session. But at every stage of a bill, the whole of it is supposed to be before the house; and consequently if words have been inserted by way of amendment, the sense of the house may again be taken respecting them at a subsequent stage. *See* PARLIAMENT.

BILL OF SALE. In Law, a contract under seal, by which a man passes his interest in goods and chattels to another, and which does not require either valuable consideration or actual transfer of the goods to support it, as between the vendor and vendee; although as between the vendee and the vendor's creditors the absence of such consideration and transfer would in general be held indicative of fraud, and invalidate the contract.

BILL OF HEALTH. A certificate or instrument, signed by proper authorities, delivered to the masters of ships at the time of their clearing out from all ports or places suspected of being infested by particular disorders, certifying the state of health at the time that such ships sailed. Bills of health are of three kinds—*clean, foul*, and *suspected*, which are self-explanatory terms.

BILL OF LADING. A memorandum, subscribed by the master of a ship, acknowledging the receipt of goods intrusted to him for transportation, and binding himself (under certain exceptions) to deliver them to the person to whom they are addressed, in good condition, for a certain remuneration or freightage. Of bills of lading there are usually triplicate copies; one for the party transmitting the goods, another for the person to whom the goods are addressed, and the third for the master.

BILL OF EXCHANGE. *See* EXCHANGE.

BILL OF RIGHTS. In Law, the declaration delivered by the two houses of parliament to the Prince of Orange, February 13. 1688, at the period of his succession to the British throne; in which, after a full specification of various acts of James II. which were alleged to be illegal, the rights and privileges of the people were asserted.

BI'LLET. In Heraldry, a bearing of which the origin is very uncertain; represented of an oblong square form, sometimes showing the thickness, and always with a flat surface. Billetty, or semée of billets, signifies that the escutcheon or charge is strewed over with these bearings, without regard to particular number or station.

BI'LLION. In Numeration, denotes a million of millions, and is expressed by 1,0000,0000,0000. The French use the same word to denote a thousand millions. The term is probably a contraction of *bis* and *million*; whence the English signification, a million of millions, appears more according to analogy. Thus biquadratic means the square of a square, or the product of two quadratics.

BILLS OF MORTALITY, are accounts of the number of births and burials within a certain district in every week, month, quarter, or year. These were first compiled in London, after the great plague of 1593; and ten years afterwards began to be returned weekly. Several of the parishes now included within the metropolis (as Marylebone and Pancras) are not within the bills of mortality. *See* MORTALITY.

BI'LOBATE. (Lat. bis, lobus, *a lobe*.) When a part is divided into two lobes, or obtuse processes.

BILO'CULAR. (Lat. bis, locula, *a cell*.) Having two cells.

BIMA'CULATE. (Lat. bis, macula, *a spot*.) When an animal, or part, is marked with two spots.

BI'MANA. (Bimana, *two-handed*.) The term applied by Cuvier to the highest order of mammalia, of which man is the type and sole genus.

BIME'DIAL. In Geometry, when two lines commensurable only in power (for example, the diagonal and side of a square) are joined together, the sum is irrational with respect to either of the two lines, and is called by Euclid a *bimedial*.

BI'NARY ARITHMETIC. (Fr. binaire, from binus, *dual*, or by *twos*.) A species of arithmetic, proposed by Leibnitz, and founded on the shortest and simplest progression; namely, that which terminates with the second cipher. In the binary notation, therefore, only two characters are required, 1 and 0, the zero having the power of multiplying the number it follows by two, as in the common notation it multiplies by ten. The number *one* is represented by 1; *two*, by 10; *three*, by 11; *four*, by 100; *five*, by 101; *six*, by 110; *seven*, by 111; *eight*, by 1000; *nine*, by 1001; *ten*, by 1010, &c. This method of notation, though it may be applied with advantage in the investigation of some properties of numbers, would be inconvenient for common purposes, on account of the great number of characters required, even when the numbers to be expressed are small. We will give an example from the *Encyclopedie Methodique* of the method of expressing a number by the binary scale, and of finding the value of a number so expressed.

It is convenient to begin with forming a table of the powers of 2, namely, 2^0, 2^1, 2^2, 2^3, &c. They are 1, 2, 4, 8, 16, 32, 64, 128. Suppose, now, it were required to express the number 230 by the binary scale. Seek in the table the greatest power of 2 contained in 230; it is found to be 128, which is the 8th number in the table; hence the expression will contain 8 ciphers, and the first on the left hand is 1. Subtract 128 from 230, there remains 102; the highest power of 2 contained in this is 64, which is the seventh number in the table. The second cipher will therefore be also 1. Subtract 64 from 102, and there remains 38. But the sixth number in the table is 32, which is contained in 38; therefore the third cipher in the expression is still 1. Subtract 32 from 38, there remains 6; but the fifth number in the table is 16, which is not contained in 6; therefore the fourth cipher of the expression is 0. The fourth number in the table is 8, which is not contained in 6; therefore the fifth cipher must also be 0. The third number in the table is 4, which is contained in 6; therefore the sixth cipher will be 1. Subtracting 4 from 6 there remains 2; but the second number in the table is 2, therefore the seventh cipher is 1. The last difference is zero; therefore the last cipher in the expression is 0. Collecting all these results, we find the number 230 is expressed in the binary scale by 11100110.

Next, suppose it were required to determine the value of the expression 110101 in the binary scale. As there are here six ciphers, we look for the sixth number in the above table, and find 32, which is the value of the first cipher. The following cipher represents the fifth number, and is consequently equal to 16. The third cipher is 0, and its value nothing. The fourth cipher corresponds to the third number in the table, and represents 4. The fifth cipher is 0, and its value nothing. The last cipher corresponds to the first number of the table, which is 1. The whole expression, therefore, 110,101, is equivalent to $32 + 16 + 4 + 1 = 53$. It has been imagined, though on very slight grounds, that traces of the binary notation are discernible among the early monuments of China.

For information on the subject of arithmetical scales, see *Leslie's Philosophy of Arithmetic*.

BINARY MEASURE. (Lat. binarius, *belonging to two*.) In Music, that in which the raising the hand or foot is equal to that of falling, usually called common time. The Italians are accustomed after a recitative to use the phrase *a tempo giusto*, to indicate that the measure is to be beat true and correct, which is otherwise conducted in the recitative in order to express passion, &c.

BI'NAT. (Lat. bis and natus, *born*.) When two bodies of the same nature spring from the same point, as often happens in the segments of leaves.

BIND. (Ger. binden, *to fasten together*.) In Music, the same as a ligature or tie for the purpose of grouping notes together.

BIND. The indurated clay of coal mines. Binding in agriculture is tying up sheaves of corn.

BINE'RVATE. (Lat. bis, nerva, *a nerve*.) In Entomology, when the wing of an insect is supported by only two nerves.

BI'NNACLE. The case or stand in which the steering compass is placed; it is fixed near the tiller or wheel. At night the compass is illuminated by a lamp placed over it.

BI'NOCLE, or BINOCULAR TELESCOPE. (Lat. binus, *double*, and oculus, *the eye*.) A telescope to which both eyes may be applied at once, and in which, conse-

quently, an object may be observed with both eyes at the same time.

BINO'MIAL. (Lat. bis, *twice*, and Gr. νομος, *law*.) In Algebra, signifies a quantity composed of two terms, connected together by the signs + or −; thus, $a + b$ and $c - 5$ are binomial quantities.

BINO'MIAL THEOREM. A formula discovered by Newton, of singular use in algebra, by which a binomial quantity may be raised to any power m, the exponent m being either a whole number or a fraction, positive or negative. The formula is this: —

$$(a+b)^m = a^m + \frac{m}{1} a^{m-1} b + \frac{m(m-1)}{1 \quad 2} a^{m-2} b^2 + \frac{m(m-1)(m-2)}{1 \quad 2 \quad 3} a^{m-3} b^3 + \frac{m(m-1)(m-2)(m-3)}{1 \quad 2 \quad 3 \quad 4} a^{m-4} b^4 + \&c.$$

And the mere inspection of the terms will give a better idea of the manner in which they are successively formed than any explanation.

When the exponent m is a whole positive number, it is evident that the series has a finite number of terms; suppose, for example, $m = 3$, then $m - 3 = 0$; and all the terms into which $m - 3$ enters as a co-efficient become equal to zero, or vanish. But on looking at the series, we find $m - 3$ entering the fifth term, and it will continue in all the succeeding; therefore, when $m = 3$ the series can only have four terms; and, generally, the number of terms of the series exceeds the exponent by one. When m is a fractional number, or is negative, the series does not terminate, and will only express approximately the value of $(a+b)^m$ when it is convergent; that is to say, when every individual term of the series is greater than that which succeeds it. For example, let the expression to be developed be $(xx + y)^{\frac{1}{2}}$, which signifies the square root of the binomial $(x^2 + y)$. Comparing this with the above formula, we have evidently —

$$(xx + y)^{\frac{1}{2}} = xx^{\frac{1}{2}} + \tfrac{1}{2}\, xx^{\frac{1}{2}-1} y$$
$$+ \tfrac{1}{2}\left(\tfrac{1}{2} - 1\right) xx^{\frac{1}{2}-2} y^2 + \&c.$$
$$= x + \frac{y}{2x} + \frac{y^2}{8x^3} + \&c.$$

a series which goes on for ever; but which, supposing x greater than unity, approaches nearer and nearer to the true value of the root of $x^2 + y$, as the number of terms included becomes greater.

In order to determine whether in any given case the series is convergent, we have only to compare two successive terms of the development of $(a+b)^m$. For example, take the fourth and fifth; rejecting the common factors, the fourth is to the fifth as $a^{m-3} : \frac{m-3}{4} a^{m-4} b$; that is, as 1 to $\frac{m-3}{4} \cdot \frac{b}{a}$; therefore the fifth will be smaller than the fourth, or the series will be convergent if $(m-3)\,b$ is smaller than $4a$. In general, let n be the order of any term in the development of $(a+b)^m$: this term will be to the succeeding in the ratio of $1 : \frac{m-n+1}{n} : \frac{b}{a}$; and the terms will always go on decreasing, or the series will be convergent when $(m - n + 1)\; b$ is smaller than $n\,a$.

The principal use of the binomial theorem is to find approximate values of the roots of quantities by expanding them into series. The demonstrations which have been given of it are very numerous, and one or other of them may be found in any work on algebra. For one of the neatest and most concise we refer to the article "Algebra" in the *Encyclopedia Britannica*, 7th edition.

BIO'CELLATE. (Lat. bis, ocellus, *an eyelet*.) In Entomology, when an insect's wing is marked with two eye-like spots.

BIO'GRAPHY. (From the Greek word βίος, *life*, and γράφω, *I describe*.) The history of the life of an individual. Biography, in the progress of literature, appears to be nearly coeval with history itself. It has been ingeniously described as "history teaching by example;" and this mode of instruction was perhaps peculiarly appropriate to early and simple times, in which the relative importance of individual men to the society in which they lived was greater than it can ordinarily be in periods of more advanced civilisation. But, although we have notices of many biographical writers among the classical authors of Greece, none of their works have been preserved to us (if we except the short narrative of the exploits of Agesilaus by Xenophon, for his celebrated Memorabilia of Socrates are rather in the form of a collection of sayings and anecdotes than a memoir) of earlier date than the Roman Empire. It is to a comparatively late age that we owe all the more interesting works of this description which antiquity has bequeathed to us, some of which are among the most popular relics of the classical ages — the *Lives of Illustrious Men*, by Plutarch and Cornelius Nepos; the *Lives of the Cæsars*, by Suetonius, a work of which the details are strictly biographical; and the *Lives of the Philosophers*, by Diogenes Laertius. Biography may be said in strictness to differ from history not merely in the extent of the subject, but also, and perhaps more characteristically, in the mode in which that subject is treated. Thus, in classical literature, the works of Quintus Curtius and Arrian, although devoted exclusively to the actions of a single individual (Alexander), are not usually termed biographies; not only because the individual in question was the leader and foremost character in a course of great public events, but also because those public events form the subject matter of their works, and not the more peculiar details of the personal life of their heroes. They are therefore more accurately denominated histories than biographies. On the other hand, the *Lives of the Twelve Cæsars* by Suetonius form, as has been said, a series of biographies, although the persons who furnish the subject were, like Alexander, arbiters of the destinies of a great part of mankind; because the details which they contain are chiefly of a private and personal nature. It is the object of history, among its other lessons, to make us acquainted with the influence which the actions, the characters, and the thoughts of individual men have produced on the course of events affecting society in general: conversely, it appears to be the province of the biographer to detail the effects which have been produced by external occurrences and circumstances on the character and conduct of individuals. *See* Memoir.

BIPE'CTINATE. (Lat. bis, pecten, *a comb*.) When a part has two margins toothed like a comb.

BI'PELTATE. (Lat. bis, pelta, *a buckler*.) When an animal or part has a defence like a double shield.

BIPU'PILLATE. (Lat. bis, pupilla, *a pupil*.) In Entomology, when an eye-like spot on the wing of a butterfly has two dots or pupils within it of a different colour.

BIQUADRA'TIC. In Algebra, denotes the power immediately succeeding the cube; that is, the square of the square, or fourth power.

BIQUADRA'TIC EQUATION. Is an equation in which the unknown quantity rises to the fourth, but not to a higher power. An equation of this kind, when complete, is of the form $x^4 + Ax^3 + Bx^2 + Cx + D = o$, where A, B, C, and D, denote any known quantities whatever. Lewis Ferrari, an Italian geometer, and a pupil of the celebrated Cardan, made the discovery that the resolution of a biquadratic equation can always be reduced to that of a cubic equation. Of the various ways in which this reduction can be effected, the following, proposed by Euler, and explained at length in his *Algebra*, is perhaps the simplest. The first step of the process is to transform the given equation into another in which the second term is wanting. This can always be done by assuming $y - \frac{1}{4}A = x$, and substituting it for x in the proposed equation; a new equation will result, having the form

$$y^4 + p\,y^2 + q\,y + r = o, \qquad (1)$$

and it is only to the solution of this that our attention need be confined.

Assume $y = \sqrt{a} + \sqrt{b} + \sqrt{c}$, and suppose a, b, c, to be three roots of the cubic equation $z^3 + Pz^2 + Qz - R = o$. By the theory of equations the co-efficient of the second term is the sum of all the roots with their signs changed; the co-efficient of the third is the sum of the products of the roots combined by pairs; and the last term is the product of all the roots with the signs changed. We have therefore $a + b + c = -P$, $ab + ac + bc = Q$, and $abc = R$. From the assumed equation $y = \sqrt{a} + \sqrt{b} + \sqrt{c}$, we get by squaring $y^2 = a + b + c + 2(\sqrt{ab} + \sqrt{ac} + \sqrt{bc})$; whence, substituting $-P$ for $a + b + c$, and transposing

$$y^2 + P = 2(\sqrt{ab} + \sqrt{ac} + \sqrt{bc}).$$

Squaring this equation also, we get after reduction $y^4 + 2Py^2 + P^2 = 4(ab + ac + bc) + 8\sqrt{abc}\,(\sqrt{a} + \sqrt{b} + \sqrt{c})$, which, on substituting R and y for their values given above, becomes

$$y^4 + Py^2 + P^2 = 4Q + 8y\sqrt{R},$$

and by transposing

$$y^4 + 2Py^2 - 8y\sqrt{R} + P^2 - 4Q = o. \qquad (2)$$

Now, one of the roots of this biquadratic equation is $y = \sqrt{a} + \sqrt{b} + \sqrt{c}$; and a, b, c, are the three roots of the cubic equation, $z^3 + Pz^2 + Qz - R = o$; consequently, by resolving the cubic we get the values of a, b, c; and thence y, the root of the biquadratic, becomes known.

To apply this solution to the proposed equation (1), the co-efficients P, Q, R, of the resolved equation (2), must be determined in terms of p, q, r. Comparing the two equations,

$$y^4 + py^2 + qy + r = o, \qquad (1)$$
$$y^4 + 2Py^2 - 8\sqrt{R}y + P^2 - 4Q = o, \qquad (2)$$

we find $2P = p$, $-8\sqrt{R} = q$, $P^2 - 4Q = r$; whence $P = \frac{1}{2}p$, $Q = \frac{p^2 - 4r}{16}$, $R = \frac{q^2}{64}$. It follows, therefore,

that the roots of the proposed equation are expressed generally by $y = \sqrt{a} + \sqrt{b} + \sqrt{c}$, where a, b, c denote the roots of the cubic equation

$$z^3 + \frac{p}{2} z^2 + \frac{p^2 - 4r}{16} z - \frac{q^2}{64} = o. \qquad (3)$$

All the four roots of the biquadratic are involved in the expression $y = \sqrt{a} + \sqrt{b} + \sqrt{c}$; in order to discover each of them in particular, it is necessary to consider the changes of sign of which they admit. As the square root of any quantity a may be either $+\sqrt{a}$ or $-\sqrt{a}$, each of the three quantities, $\sqrt{a}$, $\sqrt{b}$, $\sqrt{c}$, may have either the sign $+$ or $-$ prefixed to it; whence the formula will give *eight* different expressions. But as the product of the three roots, $\sqrt{a}$, $\sqrt{b}$, $\sqrt{c}$, is equal to $\sqrt{R}$ or to $-\frac{1}{8} q$, it is obvious that when q is positive, their product must be negative, and this can only be the case when either only one or all three of them are negative. When q is negative the product must be positive, which can only be the case either when all three are positive, or two of them negative. There are consequently only four different expressions for q positive, and four for q negative, which in either case form the four roots of the biquadratic equation.

The co-efficients of the equation (3) involve fractions; but these may be removed by assuming $v = 4z$, and substituting for z its value in terms of v. It then becomes, more simply,

$$v^3 + 2pv^2 + (p^2 - 4r)v - q^2 = o, \qquad (4)$$

the roots of which are $\frac{1}{4}a$, $\frac{1}{4}b$, $\frac{1}{4}c$.

The rule for the resolution of a biquadratic equation is therefore as follows: —

Let $y^4 + py^2 + qy + r = o$ be the proposed equation, wanting its second term. Form the cubic equation $v^3 + 2pv^2 + (p^2 - 4r)v - q^2 = o$, and find its roots, which call a, b, c. Then the roots of the proposed biquadratic are,

when q is negative,	when q is positive,
$y = \frac{1}{2}(\sqrt{a} + \sqrt{b} + \sqrt{c})$	$y = \frac{1}{2}(-\sqrt{a} - \sqrt{b} - \sqrt{c})$
$y = \frac{1}{2}(\sqrt{a} - \sqrt{b} - \sqrt{c})$	$y = \frac{1}{2}(-\sqrt{a} + \sqrt{b} + \sqrt{c})$
$y = \frac{1}{2}(-\sqrt{a} + \sqrt{b} - \sqrt{c})$	$y = \frac{1}{2}(\sqrt{a} - \sqrt{b} + \sqrt{c})$
$y = \frac{1}{2}(-\sqrt{a} - \sqrt{b} + \sqrt{c})$	$y = \frac{1}{2}(\sqrt{a} + \sqrt{b} - \sqrt{c})$.

BIRA′DIATE. (Lat. bis, radius, *a ray*.) When a part has two rays.

BIRCH. A hardy tree inhabiting the north of Europe, Asia, and America. The common birch (*Betula alba*) is valuable for its capability of resisting extremes of both heat and cold; its timber is chiefly employed for fire wood. Its bark is extremely durable. The American birch (*B. lenta*) produces a hard heavy timber, much used by cabinet-makers; and the bark of *B. papyracea* is employed by the North American Indians for a variety of useful purposes.

BI′RDLIME. A glutinous substance extracted by boiling the bark of the holly tree; a similar substance may be obtained from misletoe, from the young shoots of elder, and some other plants.

BIRD OF PARADISE. A name originally applied to the species *Paradisea apoda*, Linn.; of which the skins, deprived of the wings, the feet, and the tail, have long formed a high-priced article of export from the eastern parts of the world. The value of these mutilated specimens of natural history arises chiefly from the extraordinary development and light and beautiful structure of the plumes which grow from the scapular and lateral regions of the body; and these plumes, combined with the velvety texture and brilliant metallic reflections of the ordinary feathers, especially those covering the head, render skins of the *Paradisea* ornaments highly and justly esteemed by the fair inhabitants of the most civilised countries. The presence of the remarkable plumage just alluded to, and the constant absence of the ordinary organs of locomotion in the imported specimens, easily gave rise to strange speculations as to the nature of the rare bird of the east; and the older naturalists delighted to describe it as destitute of feet, dwelling constantly in the air, wafted about in the bright beams of the sun independently of the ordinary mechanism of wings, and nourished with dew, and the nectar and even odour of flowers. To beings thus imagined to be raised above the dull earth, to enjoy etherial food and a perpetual habitation in the air, no name could be more appropriate than Birds of Paradise or Heaven. The march of inquiry has, however, dispelled the fancied attributes and false charms of these lovely beings, and has restored to them their wings and feet. The latter, indeed, are remarkable for their robustness: they have three toes in front and one behind, as in other *Passeres* of Cuvier, with the middle toe shorter than the tarsus, the outer toe united to it at its base, and the inner one joined to it for half the length of the first phalanx. The form of the beak corresponds with that which characterises the tribe *Conirostres* of Cuv.; and their true food, which consists not only of the pulpy and farinaceous parts of fruit, but also of worms, insects, the eggs and young of smaller birds, and even carrion, causes them to be ranked with the family of *Omnivores*, Cuv. In fact, they closely resemble in their habits our magpies and jays. The principal species of the genus *Paradisea* are the Great or Common Bird of Paradise (*Par. apoda* of Linnæus); the Royal Bird of Paradise (*Par. regia*); the Red Bird of Paradise (*Par. rubra*); the Magnificent Bird of Paradise (*Par. magnifica*); the Six-threaded Bird of Paradise (*Par. sexesetacea*), which is characterized by three long and thread-like feathers, which grow from each side of the body; the Superb Bird of Paradise (*Par. superba*), which is smaller than the preceding, but perhaps the most beautiful of the genus; the Small Bird of Paradise (*Par. minor*), which measures about nine inches from the point of the bill to the end of the tail; and, lastly, the White Bird of Paradise (*Par. alba*).

BIRD PEPPER. The small *Capsicum*, a species of the plant which affords Cayenne pepper.

BIRDS. In Heraldry, are said to be rising, displayed, close, volant, &c. according to the different postures in which they are represented. Birds of prey, and cocks, when beaked and legged of a different tincture from the body, are said to be *armed* of that tincture.

BIRD'S EYE VIEW. In the Fine Arts, a term used to denote a view arranged according to the laws of perspective, in which the point of sight or situation of the eye is placed at a very considerable height above the objects viewed and delineated. In architectural representations, it is used chiefly for the purpose of exhibiting the disposition of the different courts or quadrangles and roofs of a building. It is a useful method of representing battles, as also of giving a general notion of a small district of a country. As before observed, it is entirely dependent upon the same principles as those detailed in the article PERSPECTIVE, which see.

BIRD'S MOUTH. In Architecture, an interior angle or notch, cut across the grain at the extremity of a piece of timber for its reception on the edge of another piece; as a rafter, for instance, is received on a pole plate. Bird's mouth signifies also the internal angle of a polygon, its external angle being called a bull's nose.

BIRTH, EVIDENCE OF. By the French code civil it is required that a declaration shall be made of every birth to the proper officer, within three days, with production of the child. The "act of birth," setting forth the time and place of the event, sex and name of the child, and description of the father, is then immediately drawn up in the presence of two witnesses. It is entered on the register, and a copy kept by the parent. (*Code Civil*, art. 55.) In England by the 70th Canon, and statutes of 6 & 7 William 3. and 4 G. 4. c. 76., the minister of every parish is required to keep a register of births. But now, by the recent act for registering births, deaths, and marriages, 6 & 7 W. 4. c. 86., it is enacted that the parent, or occupier of a house in which a child is born, *may*, within 42 days after the birth, give notice to the district registrar; and *shall* give such information on being requested by the district registrar within the same time. After 42 days, the birth may be registered only in presence of the superintendant registrar, and on a peculiar declaration. After six months, registration of a birth cannot take place. Certified registers of births, as well as deaths, are to be forwarded after a certain time to the superintendant registrar, and copies of registers to the general register office. (Sects. 19. 21, 22, 23. 33, 34.)

BIRTH, or BERTH, OF A SHIP. The ground or space in which she is anchored, and which is said to be a *good birth*, or a *bad birth*; also, an apartment, as the midshipman's birth; also, the space allotted a seaman to sleep or hang his hammock in.

BIS. (Lat. *twice*.) In Music, a word placed over passages which have dots postfixed to one bar, and prefixed to a subsequent bar, signifying that the passage between the dots is to be twice played.

BI′SCUIT. (Fr. bis, *twice*, and cuit, *baked*.) In Sculpture, a species of porcelain, of which groups and figures in miniature are formed, which are twice passed through the furnace or oven. It is executed without glaze upon it. In Pottery, this term is applied to earthenware and porcelain, after it has been hardened in the fire, and before it receives the glaze: in this state it is permeable to water.

BISE′TOUS. (Lat. bis, seta, *a bristle*.) In Zoology, when an animal or part is furnished with two bristle-like appendages.

BISE′XUAL. (Of two sexes.) Is a term applied to flowers which contain both stamens and pistil within the same envelop: it is the same as the word hermaphrodite in botany.

BI′SHOP. (A word contracted from the Greek ἐπίσκοπος, Lat. episcopus, signifying literally an overseer.) In all denominations of Christians which admit the episcopal form of government, the bishop is the superior of the three orders, standing in rank and office distinct from the presbyter or priest. (*See* art. EPISCOPACY.) This distinct office consists in the power of ordination, confirmation, and consecration, none of which ceremonies may be performed by an inferior clergyman. The clergy of a diocese are subjected also to the ecclesiastical authority

of their bishop, who alone institutes to benefices, licenses curates, and has considerable discretionary power in requiring the residence of his clergy on their cures, and in superintending the discharge of their duties in them.

The mode of the appointment to bishoprics varies in different establishments. In early times the bishop was generally elected by his clergy. In the middle ages the pope assumed in most cases the absolute nomination, which claim has been given up in later times in many Catholic countries, where the king or clergy recommend, and the holy father only ratifies the appointment. In England the appointment is virtually in the hands of the sovereign, who upon the demise of the bishop receives from the dean and chapter intimation of the event, with a request for permission to supply the vacancy. The king accords his permission to that effect, and at the same time recommends a person to their choice — a recommendation which is equivalent to a command, as it cannot be waived without incurring the severe penalties of a præmunire.

BI′SMUTH. A brittle, yellowish-white metal, of a crystalline texture. Its specific gravity is 10·; it fuses at 476°, and at a red heat it sublimes in close vessels. It conducts heat less perfectly than most of the other metals. When strongly heated it burns with a bluish white flame, and is rapidly oxidized. Its equivalent upon the hydrogen scale is 71; and it forms only one salifiable oxide, the equivalent of which is 79. When nitrate of bismuth is dropped into water a white powder is thrown down, formerly called *magistery of bismuth* or *pearl white:* it is a subnitrate. A brown *peroxide of bismuth* is obtained by fusing the protoxide with caustic potash. Some of the alloys of bismuth are remarkable for their fusibility: a compound of 8 parts of bismuth, 5 of lead, and 3 of tin, melts in boiling water, and is commonly called *fusible metal.* The ores of bismuth are not common; but it occurs *native*, and combined with oxygen, sulphur, and arsenic. The Germans call it *wismuth.*

BI′SON. The trivial name of certain species of the Linnæan genus Bos, which differ from their congeners in having fourteen (*Bos bison*), or fifteen (*Bos Americanus*), instead of thirteen pairs of ribs. The common bison of the north of Europe (*Bos bison*), and the American bison, or bonassus (*Bos Americanus*), are the only known existing species of this group.

BISPINO′SUS. (Lat. bis, spina, *a spine.*) When an animal or part is armed with two spines.

BISSE′XTILE. (Lat. bis, *twice*, and sextilis, *sixth.*) The name given to the year which contains 366 days. The calendar used in all European countries is founded on that of the Romans, as reformed by Julius Cæsar. In the calendar of Cæsar, the length of the year was fixed at 365¼ days; and in order that the year should always begin with the beginning of a day, it was directed that every fourth year should contain 366 days, the other years having each 365. The additional day, which thus occurred every fourth year, was given to February, the shortest month, and was inserted in the calendar between the 24th and 25th days. In the peculiar method of reckoning the days of the month adopted by the Romans, namely, of reckoning backwards from the 1st of the succeeding month, it would have been very inconvenient to have interrupted the order of numeration; accordingly the 24th, which was called *sexto Calendas Martii*, was reckoned twice, and the supernumerary or repeated day called *bis sexto Calendas.* Hence the term *bissextile.* In English, *leap year* has the same signification.

In the Julian calendar every fourth year was bissextile; but this supposes the year to be 365¼ days, which errs in excess by 11 minutes 10·35 seconds. Accordingly, in the course of a few centuries, the error will amount to days, and cause the commencement of the year to change its place with respect to the seasons. When the Julian calendar was introduced, the equinox fell on the 25th of March; in 1582, when the calendar was reformed by Pope Gregory XIII., it had fallen back to the 11th; and as it was then supposed that the error of the Julian calendar amounted to three days in 400 years, it was ordered that the intercalary day should be omitted in all the years which terminate centuries, excepting those which are multiples of 400. The Gregorian rule of intercalation is therefore as follows: — Every year of which the number is divisible by 4 is a leap year; excepting the centesimal years, which are only leap years when divisible by 4 after suppressing the two zeros. Thus 1600 was a leap year; but 1700, 1800, and 1900, which would be bissextile in the Julian calendar, are common years in the Gregorian.

This regulation, though it would for a long time preserve the commencement of the year at the same place in the seasons, is not yet quite correct. It supposes the length of the year to be 365 days 5 h. 48 m. 12 seconds, which is too great by 22·38 seconds; an error which amounts to a day in 3866 years. As this number 3866 approaches to 4000, it was proposed by Delambre to correct the Gregorian rule by making the year 4000 and all its multiples common years. Should our present calendar continue to be in use 2000 years hence, posterity may then begin to consider whether they will adopt this suggestion. *See* CALENDAR.

BI′STORT. The root of the *Polygonum bistorta*, an indigenous plant; it is used in medicine as a powerful astringent.

BI′STRE. In Painting, a dark brown colour, made from the soot of dry wood, whereof for this purpose beech is preferable.

BI′SULCATE. (Lat. bis, *twice*, sulcus, *a fissure.*) In Mammalogy, a term signifying a foot resting upon two hoofed digits.

BIT. That part of the bridle which goes into the mouth of a horse.

BI′TTER PRINCIPLE. This term has been applied to certain products of the action of nitric acid upon animal and vegetable matters of an intensely bitter taste. *See* CARBAZOTIC ACID.

BI′TTERN. *See* ARDEA.

BITTERN. The residue of sea water after the common salt has been separated by evaporation. It contains *muriate of magnesia*, which gives it a bitter taste.

BITTER SALT. Sulphate of magnesia, or Epsom salt.

BITTER SPAR. A Mineralogical term, generally applied to certain crystallized varieties of *dolomite*, or double carbonates of lime and magnesia. It occurs in rhomboidal crystals, consisting of about 55 *per cent.* of carbonate of lime and 45 of carbonate of magnesia, sometimes with traces of iron and manganese.

BITU′MEN. (From πιτυς, *the pitch tree;* because it resembles pitch.) A variety of inflammable mineral substances, which, like pitch, burn with flame in the open air, is included under this term: such as *naphtha*, *pitroleum*, and *asphaltum.*

BITUMEN. Mineral pitch.

BITU′MINOUS SHALE. An argillaceous shale impregnated with bitumen: it commonly accompanies coal.

BIVA′LVES. (Lat. bis, *two*, and valva, *a valve.*) A term commonly applied to the Lamellibranchiate Acephalous Molluscs, on account of the structure of their shell, which consists of two parts or valves, joined together by an elastic ligament at the cardo, or hinge. The testaceous covering of the Palliobranchiates is also composed of two valves or shelly pieces; but these are never joined by elastic ligament.

BI′VOUAC. (Fr.) A term in the Military art, employed to denote the system by which soldiers on a march, or in expectation of an engagement, remain all night in the open air, in contradistinction to the systems of encampment and cantonment. This word is derived from the Lat. bis, *twice*, and the German wache, *a guard*, and signified originally the guard which was selected from the body of a regiment to keep watch during the night.

BIXA′CEÆ. A small natural order of plants, so called after the genus Bixa, the genus which produces the substance called arnotto, with which English cheeses are dyed of their peculiar reddish ochre colour. The species are all trees or shrubs inhabiting the tropics.

BLACK. (Sax. blac.) In Painting, the darkest colour of all; whereof the different sorts are lamp black, ivory black, Frankfort black, Spanish black, and Hart's black.

BLACK BIRD. *See* TURDUS.

BLACK CAP. This term is generally applied and understood to signify a species of frugivorous warbler (*Curruca atracapilla* of Bisson); but it is also occasionally given to the great titmouse (*Parus fringillago*), the marsh titmouse (*Parus palustris*), the black-headed bunting (*Emberiza schœmilus*), the stonechat (*Rubetra rubicola*), and even to the black-headed gull.

BLACK COCK. The name of a native species of grouse (*Tetrao*).

BLACK FLUX. A mixture of carbonate of potash and charcoal, obtained by deflagrating *tartar* with half its weight of *nitre.*

BLACK JACK. A term applied by the miners to certain sulphurets of zinc: the ore is also called *blende.*

BLACK LEAD. *See* PLUMBAGO and GRAPHITE.

BLACK LETTER. Is the name now applied to the old English or modern Gothic letter, which was introduced into England about the middle of the fourteenth century, and became the character generally used in MS. works before the art of printing was publicly practised in Europe. On the application of that art to the multiplying of books, about the middle of the fifteenth century, the block books, and subsequently those printed with moveable types, were in this character, to imitate writing, and were disposed of as manuscripts; and so perfect was the imitation, that it required great discrimination to distinguish the printed from the written. The first printed Bible, known as "the Mentz Bible without date," was an instance of this. Fust, the printer, sold copies in Paris as manuscripts; and as the demand increased on account of their beauty and correctness, he not only promptly supplied that increased demand, but even lowered the price: this

excited suspicion; and on comparing the copies they were found to be perfect facsimiles of each other, and being produced with such rapidity it was held to be totally impossible for the most expert scriptores to execute them with equal accuracy and despatch; and Fust was accused of producing them by means of magic. To avoid punishment for this crime, he was obliged to reveal the process by which they were produced.

Books printed before the year 1500 are generally in this character, and are styled black-letter books.

BLACK WASH. A lotion composed of calomel and limewater.

BLA'NCHING. In Gardening, is the whitening of the stems, stalks, or leaves of plants by tying them together, or earthing them up, so as to exclude the light, and thus to diminish the intensity of their native properties.

BLA'NK VERSE. In some modern languages, the heroic verse of five feet without rhymes. Blank verse is peculiar to the Italian, English, and German languages; having been imported into the two latter from the first. In Italian the line is of eleven syllables; and is used invariably in the drama, and frequently in serious poetry, epic or didactic. In English it was also first adopted by the dramatists, and transferred to epic poetry by Milton. The Miltonic verse is constructed with closer attention to the melody of the cadence and cæsura than the dramatic: it admits also less frequently of the eleventh syllable, which in English poetry must be regarded as a sort of license; while Shakspeare and other dramatists occasionally double the short syllable at the end, and thus extend the number to twelve.

BLAPS. A Fabrician genus of Coleopterous insects, now the type of a family (*Blapsidæ*), characterized by the absence of wings; maxillary palpi terminated by a large hatchet-shaped joint; body oblong and oval. All the species are of a dark or black colour, and have the elytra soldered together, and bent down at the sides of the abdomen so as to embrace that part. There are three British species of the genus *Blaps* proper, which are known by the trivial names of "darkling" or "church-yard beetles," and are regarded by the vulgar of this and other countries as insects of evil omen.

BLAS'PHEMY. (Gr. *βλασφημια*, probably from *βλαπτω, I injure; φημη, rumour.*) According to its supposed etymology signifies the offence of using injurious language, as calumny, reviling, &c.; and in this sense it is used in the New Testament; the word "railings," in 1 Tim. vi. 4., being in the original "blasphemies." But in the modern and restricted sense, "blasphemy" signifies the use of insulting, or derogatory, or unbelieving language, with respect to God and divine things. Under this meaning it has been considered a civil crime in most Christian countries, in imitation of the practice which prevailed among the Jews. (Levit. xxix.) In England, by common law, it was punishable with fine, imprisonment, and other corporal punishment. By 9 W. 3. c. 35. it was first made a statutable offence, and extended so as to comprehend even the mere denial of some fundamental doctrines of Christianity; and subjected to very severe inflictions. Unitarians were relieved from the penalties of this act by 3 G. 3. c. 170. But it is almost obsolete in practice with respect to other offenders.

BLASTE'MA. In Botany, the axis of growth of an embryo; that is to say, the plumula, the radicle, and the part which connects them, the cotyledons being removed.

BLASTEMA. In Anatomy, the homogeneous gelatinous and granular basis of the ovum, in which the organic elements characteristic of the different tissues are deposited in the early stages of development.

BLA'STING. *See* MINING.

BLASTOCA'RPOUS. (*Βλαστος, a germ*, and *καρπος, fruit.*) That kind of fruit which germinates inside the pericarp, as the mangrove.

BLASTODE'RM. (Gr. *βλαστος, germ, δερμα, skin.*) In Anatomy, the germinal skin or membrane, or that granular membrane or stratum which lies immediately beneath the membrana vitelli of the ovum, and which is the seat of development of all parts of the body of birds.

BLA'STUS. (*Βλαστανω, I germinate.*) A name sometimes given to the plumula and radicle of grasses.

BLA'TTA. A genus of nocturnal Orthopterous insects, commonly called cock-roaches, or black beetles. In modern Entomology, it forms the type of a family, including many genera.

BLA'ZONRY. The art of deciphering coats of arms; also, that of expressing or describing a coat of arms in appropriate language. The word is supposed to be derived from the German *blasen*, to blow, and to have originated in the ceremonial of tournaments, from which so many other terms and usages in heraldry are derived; it having been customary on these solemn occasions for the herald to blow a trumpet when he called out the arms of a knight on ushering him into the lists. Blazonry requires a knowledge of, 1. The points of the shield, which are nine in number (*see* POINTS); 2. The field, that is, the tincture or tinctures forming the ground of the coat (*see* TINCTURE); 3. The charges, or devices borne on the field (*see* CHARGE); 4. The ordinaries.

BLEA'CHING. (Ger. bleichen.) This process consists in a series of operations, by which the natural colours of various substances are discharged, so as to whiten them. It is effected either by the action of various solvents, aided by exposure to light, air, and moisture, upon the bleaching ground; or by the aid of chlorine. Cotton is more easily bleached than linen, in consequence of its being originally whiter, and having a less powerful attraction for the colouring matter. In bleaching these goods upon the old principle, warm water is first liberally applied to remove the weaver's paste or dressing; they are then *bucked*, or boiled in a weak alkaline ley; and after having been well washed, are spread out upon the grass, so as to be freely exposed to the joint agencies of light, air, and moisture; the bucking and exposure are alternately repeated as often as necessary; the goods are *soured*, that is, immersed in water slightly acidulated by sulphuric acid; lastly, they are very thoroughly washed and dried. By these operations the texture of the goods is to a certain extent impaired, and much time is required to complete the process, which also cannot be carried on in the winter months. But the exposure upon the bleaching ground is now to a great extent discontinued; and the same effect is obtained, after the process of bucking, by the action of weak solutions of *chlorine*, or of *chloride* of lime, which, if skilfully used, can scarcely be said to injure the goods more than the long-continued exposure. The theory of bleaching has not been satisfactorily developed; but, from such experiments as have been made in reference to it, it appears to be a process of oxidizement, and to depend upon some peculiar influence of *nascent* oxygen upon the colouring matter.

The colour of manufactured wool depends partly upon its own oil, and partly upon the applications made to it in the loom. These are got rid of in the fulling mill by the joint action of fullers' earth and soap; the cloth is then well washed and dried, and is tolerably white; if the slight yellow tint which it retains is objectionable, it is prevented by adding a little stone-blue to the washing water, or by exposure to the fumes of burning sulphur; this latter method, however, gives it a harsh feel, and if afterwards soaped its yellowishness returns.

The colour of raw silk depends upon a natural yellow varnish, which is got rid of by boiling it in white soap and water, and by repeated rincings. Certain articles of wove cotton, such as stockings, are bleached as usual, and finished by the action of *sulphurous acid*, or the fumes of burning sulphur. Straw is also whitened by a similar operation; and hence bleached straw hats are apt to have a disagreeable sulphurous smell. A good account of bleaching will be found in ***Parkes' Chemical Essays***.

BLE'ACHING POWDER. Chloride of lime, made by exposing slaked lime to the action of chlorine.

BLENDE. Native sulphuret of zinc.

BLE'NNIUS. (Gr. *βλεννα, slime.*) In Ichthyology, a genus of Acanthopterygious fishes, of the family of Gudgeons (*Gobioidæ*), remarkable for the quantity of mucus secreted from the skin, and for the viviparous generation of some of the species, of which the *Blennuis pholis*, a species common along the shores of Britain, is an example.

BLE'NNORRHŒ'A. (Gr. *βλεννα, mucus*, and *ῥεω, I flow.*) An inordinate discharge or secretion of mucus.

BLE'PHARITES. (Gr. *βλεφαρον, the eyelid.*) Inflammation of the eyelids.

BLIGHT. A term in common use for supposed atmospherical injuries received by plants. Before effects were traced to their causes with the same care that they are at present, the sudden discolouration of the leaves of plants, their death, or their being covered with minute insects or small excrescences, was called by the general name of blight; and this blight was attributed to some mysterious influence in the air, to the east wind, or to thunder, because these states of the atmosphere commonly accompanied the phenomena alluded to. It is now found that what is called blight is in some cases the effect of insects, to the progress of which the dry state of the atmosphere produced by east wind is peculiarly favourable; while in other cases, it is caused by parasitical fungi. The appearance of these fungi on corn crops is frequently designated by farmers as the fire blast; while on peach and other trees in gardens it is called mildew. The sudden death of plants, and also the withering and drying up of part of their leaves and branches, to which appearance the term blight should perhaps be restricted, are produced by the transpiration of water from the leaves taking place with greater rapidity than it can be supplied by the absorption of the roots. In very hot weather in summer, branches of fruit trees trained against walls, or of gooseberry bushes on espaliers, are sometimes withered up in a few minutes from this cause. What countrymen call the blight on standard apple or other fruit trees in orchards is commonly nothing more than the injuries done the leaves

and buds by the caterpillars of certain moths; that on thorn hedges, by the caterpillar of the saw fly, or of the ermine, or of some other moths; and that on roses, by the aphides or green fly.

BLIND WORM. An ophidian or serpent-like reptile, which is the type of the genus *Cecilia* (see that word). The term is also sometimes applied to the slow-worm. *See* ANGUIS.

BLI'NKERS. Expansions of the sides of the bridle of a horse, to prevent him from seeing on either side, but at the same time not to obstruct his vision in front.

BLIS'TER-FLY. *See* CANTHARIS.

BLOCK. (Teutonic.) In Architecture, a large unworked mass of marble or other stone. It is also vulgarly used to denote a modillion in a cornice.

BLOCK. In Navigation, the case that contains the wheel or *sheeve* of the pulley (which last term is not used at sea). Two or more blocks, with the rope, constitute a *tackle* (pronounced tācle). Blocks are also the pieces of wood and iron on which, piled up, the ship's keel is supported when she is in dock.

BLOCKA'DE. In International Law, the right to blockade the ports of an enemy in war, and to exclude neutrals, is limited by the following recognised principles: 1. The blockade must be substantial, by means of a sufficient force to prevent the entry or exit of vessels; otherwise a neutral is not bound to respect it. 2. It is essential that the neutral should have notice of the blockade; otherwise his ship cannot be justly condemned. A counter notice should also be given by the blockading power when the blockade has ceased. In England, a blockade is properly declared by the king in council.

BLO'CKING COURSE. In Architecture, a finishing course of masonry above a cornice.

BLOCK TIN. Tin cast into blocks or ingots: it is generally less pure than *grain tin*.

BLOOD. The fluid which circulates in the heart and blood-vessels. When viewed under the microscope it appears to consist of very minute *red globules* or spheroids floating in a colourless fluid. The average quantity in an adult man is estimated at about 28 lbs.: it is of two distinct colours in the arterial and venous systems; florid red approaching to scarlet in the former, and dark crimson in the latter. Its specific gravity is between 1·050 and 1·070. When drawn from its vessels it gelatinises or coagulates in the course of a few minutes of common temperature, and soon separates spontaneously into *serum* and *coagulum*. The serum is a yellowish soapy-feeling fluid, of the specific gravity of about 1·030. It exhibits a slight alkaline reaction upon test papers; when heated it becomes opaque, and at 156° it coagulates. It is also coagulated by alcohol, and by most of the acids; acetic acid and ether do not coagulate it; solutions of corrosive sublimate, of subacetate of lead, and of chloride platinum occasion precipitates in it, even when considerably diluted with water. These properties of serum are dependent upon the presence of a peculiar proximate animal principle called *albumen*; the same substance, and with very nearly the same properties, constitutes the *white of egg*, the coagulability of which by heat is well known. Besides the above there is another most delicate test of albumen in solution, which consists in adding to the liquid suspected to contain it a little strong *acetic acid*, and afterwards a few drops of *ferrocyanate of potash*. If albumen be present, a white cloud is produced. This is even a more accurate test than corrosive sublimate. White of egg is coagulated by ether, while serum is not. According to Marcet 1000 parts of serum of human blood are composed of water 900, albumen 86·8, muriates of potassa and soda 6·6, muco-extractive 4, carbonate of soda 1·65, sulphate of potassa 0·35, earthy phosphates 0·60.

The coagulum of the blood is of a more or less firm texture, and has a greater specific gravity than the serum. It contains the colouring particles of the blood; and when carefully washed, these are carried out of it, and a tenacious whitish matter remains, which has been termed *fibrine*, but which, in all essential points, has the properties of coagulated albumen.

The colouring matter of the blood, *hæmatosine*, may be obtained by evaporating its aqueous solution at a temperature below 100°; it then appears almost black, but resumes its red colour when dissolved in water. It is soluble in acids and in alkalies: these solutions are dark-coloured; but when mixed, so as to become *neutral*, the hæmatosine falls of a bright red colour. Accordingly, when the clot of blood is put into acids it becomes brown or blackish, and is very similarly discoloured by alkalies; but most neutral salts render it florid. Dr. Stevens has shown that carbonic acid in venous blood is the probable cause of its dingy hue, and that the saline matter of the serum confers the florid red upon arterial blood; and that by washing the saline matters out of the bright coagulum of arterial blood it gradually loses its brilliancy and resembles venous coagulum.

The following table shows the results of an analysis of human blood by Lecanu (*Annales de Chimie et Physique*, vol. xlviii.); considered *quantitively*, it must only be taken as a mean or approximate result.

Water	780·145
Fibrine	2·100
Colouring matter	133·000
Albumen	65·090
Fat and oily matter	3·740
Extractive matter	1·790
Albumen combined with soda	1·265
Chloride of sodium, potassium; Carbonates, Phosphates, Sulphates of potassa and soda	8·370
Carbonates of lime, magnesia; Phosphate of lime, magnesia, iron; Peroxide of iron	2·100
Loss	2·400
	1000·000

BLOOD ROOT. The root of the *Sanguinaria canadensis*, the juice of which is of a red colour.

BLO'ODSTONE. A dark green silicious mineral, variegated by red spots (heliotrope).

BLO'WPIPE. An instrument by which a small jet of air is directed laterally into the flame of a lamp or candle, so as to divert it in a long slender cone upon a piece of charcoal or other substance so placed as to receive it. When a flame is thus urged by the blowpipe the extreme heat is just at the tip of the outer white flame, where the combustion is most perfect, and where substances are rapidly burned or oxidized; whilst the interior blue flame, in consequence of its excess of combustible matter, abstracts oxygen from, or *reduces*, substances. So that several metals, when thus heated before the blowpipe, are alternately oxidized and deoxidized by being placed in the outer and inner flame. The blowpipe is of important service to the chemist in enabling him to ascertain easily and quickly the effects of intense heat upon a variety of substances; and he frequently has recourse to it in order to distinguish metallic and earthy minerals from each other, and to ascertain in a general way the nature of their component parts: it is, in fact, a most important auxiliary in all cases of qualitative analysis. Several treatises have been written on the use and indications of the blowpipe: the reader is especially referred to *Faraday's Chemical Manipulation*, Sect. IV. §3.

BLU'BBER. The cellular membrane in which the oil or fat of the whale is included. *See* WHALE.

BLUE. (Germ. blau.) In Painting, the colour of the sky. It is one of the seven original colours, and is of many sorts, whereof the principal are ultramarine, prussian blue, blue bice, and indigo.

BLUFFS. High banks presenting an abrupt form towards the sea or river.

BO'A. A genus of serpents, with the transverse scutæ of the abdomen and tail in a single row, and without a rattle or spur at the end of the tail. Some species attain an immense size; but the large serpents brought to this country, and called boa constrictors, are generally *Pythons*, and natives of Asia. The true boas are from South America.

BOARD. (Equivalent to the French *bureau*.) A word applied usually to certain individuals in a collective capacity, who are intrusted with the management of some public office or department. Thus the Commissioners of Customs, the Committee of the Privy Council for the Affairs of Trade, the Commissioners of Excise, &c., when assembled to transact the business of their respective offices are styled the Board of Customs, the Board of Trade, the Board of Excise, &c. But the term Board is used also in a more general sense, being applied to any individuals appointed by competent authority to deliberate on or superintend the operations of any private business or speculation.

BOARD. (Sax. bord.) In Architecture, a piece of timber of undefined length, more than four inches in breadth, and not more than two inches and an half in thickness. The section of a board is, however, sometimes triangular, or rather trapezoidal, one edge being very thin. This is called a feather-edged board.

BOA'TSWAIN. The second of the three warrant officers of a man of war; he has charge of the boats, rigging, anchors, and cables. It his duty to *turn the hands up*, or summon the whole crew, whenever they are required for any duty. He should from the nature of his duties be an active man, and a thorough seaman. The *boatswain's mates* assist the boatswain, summon the watches or other portions of the crew to duty, and inflict punishments.

BOAT. (Sax. bæt.) A term used in a general sense to denote any small ship or vessel, whether open or decked, and which may be propelled by oars, or by

sails, or by steam. They are accordingly of very different forms and constructions, according to the different purposes they are intended to serve. Under this term are comprehended barges, cutters, pinnaces, yawls, &c. *See* SHIP; STEAM NAVIGATION.

BO'BSTAYS. Stays or strong ropes to keep down the bowsprit during the plunging of the ship, and against the upward action of the head sails (jibs, fore-staysail, &c.), and to sustain the action of the stays or ropes, which keep the foremast, fore-topmast, &c., and therefore the main-topmast, from falling aft. They are necessarily very strong; they are attached to the bowsprit by *collars* placed about ⅔ of its length outside, and to the hull of the ship, by passing through holes in the *cutwater* or projecting head, and make an angle of about 30° more or less with the axis of the bowsprit. They are often made of chains.

BO'DY. In Physics, is a term applied to any portion of matter of which the existence can be perceived by any of our senses. According to the Peripatetics, body is composed of *matter, form*, and *privation*. In modern physics, body is regarded as an agglomeration of material particles. According to the different forms in which matter exists, bodies may be *solid, liquid*, or *gaseous*.

In Geometry, *body* is synonimous with *solid*. Thus we say the five regular *bodies*, or five regular *solids*. *See* SOLID.

BOG EARTH. A soil consisting chiefly of silicious and vegetable fibre; it is often accumulated in considerable quantity where waters have deposited the mud of boggy places. Many American shrubs and other plants and flowers will only thrive in such or similar soils, so that bog earth is in great request for such purposes. It may, to a certain extent, be artificially imitated by mixing the cuttings of grass with the mud of ponds and a sufficient quantity of sharp sand.

BOHE'A. A species of black tea. *See* TEA.

BOI'LING POINT. The temperature at which liquids are rapidly converted into vapour with the phenomena of *ebullition*. Thus the boiling point of water is 212°; of alcohol, 176°; of ether, 96°; of oil of turpentine, 316°; and of mercury, 662°; these being the respective temperatures at which these bodies continuously pass into the state of vapour.

BO'LDNESS. (Sax. balð.) In the Fine Arts, that fearlessness which an artist exhibits in his designs, arising from, and grounded on, a thorough knowledge of the principles of his art. Its antagonist is tameness or insipidity.

BOLE. (Gr. *βωλος, a mass.*) An argillaceous earthy mineral, generally reddened by oxide of iron; as is the case in the *Armenian bole*, which is used in tooth-powder, and to give colour to the fish sauce called *essence of anchovies*.

BOLE'RO. A peculiar species of dance very popular in Spain, and so called from the name of its inventor.

BOLE'TIC ACID. An acid contained in the juice of the *Boletus pseudo ignarius*.

BOLE'TUS. (Gr. *βωλος, a mass.*) A genus of fungi, numerous large species of which spring from the sides of trees when the rind is decayed, forming firm fleshy masses, which are generally smooth on the upper side, and pierced with holes on the lower. The spawn of such plants often forms what is called dry-rot, insinuating its fine delicate filamentous ramifications between the tubes of the wood, forcing them asunder, and so destroying the cohesion and solidity of timber. *Boletus igniarius* and *fomentarius* are the fungi which, when cut into thin slices, dried, and prepared with saltpetre, form common amadou, or the German tinder of the shops. *B. tuberosus* is used in Sweden, as a substitute for cork. *B. bovinus* is said to be a favourite food of oxen, deer, swine, and some other animals; it is even used for human food.

BOLOGNE'SE SCHOOL. In Painting, sometimes called the *Lombard school* of painting. It was founded by the Caracci, and its object was to unite the excellencies of the preceding schools (*see* PAINTING); hence it is occasionally called the *Eclectic school*. Among the principal painters which it numbered were Domenichino, Lanfranco, Corregio, Guido, Schidone, Caravagio, Zampieri, Primaticcio, &c.

BOLO'GNIAN STONE. A sulphate of baryta, found near Bologna, which, when heated with charcoal, becomes a powerful *solar phosphorus*.

BO'LTHEAD. A globular flask with a tubular neck, used in the chemical laboratory.

BO'LUS. (Latin, *a mass.*) A very large pill; or a medicine formed into an olive-shaped mass, not too large to be swallowed.

BOMB. In Artillery, a hollow ball or shell of cast-iron, having an orifice through which it is filled with gunpowder, and into which, when filled, a fusee is inserted, so adjusted that when the bomb falls at the place intended, the fusee ignites the powder in the shell, and blows it to pieces. The havoc which is thus produced in a besieged town or the ranks of an enemy is often very great. Bombs, or shells, as they are more frequently called, are of all sizes, from about 18 inches downwards, and are in general thrown from mortars or howitzers; sometimes from cannon. They appear to have been first used as part of the regular materiel of an army about the year 1634, in the wars of the Netherlands. The principal art in throwing shells is to make them fall at or near a given point. For this purpose the distance is calculated, and the charge of powder and elevation of the mortar regulated accordingly. Theoretical rules are of no great use. They must be derived from experiment and practice.

BO'MBARDIERS. *See* BRACHINUS.

BO'MBAX. (Βομβαξ.) A genus containing many species of very large trees, whose capsules are filled with a fine cottony substance enveloping the seeds. It gives its name to the natural order *Bombaceæ*, allied to Malvaceous plants, where it is associated with the celebrated Baobab, and many more gigantic inhabitants of tropical forests. The bombax trees are remarkable for forming on their sides next the ground huge buttresses, projecting so far from the parent trunk as to be capable of screening many men. The quantity of cotton yielded by these trees is enormous, and often covers the earth around the roots to the depth of several feet; it is unfortunately of too short a staple to be used for manufacturing purposes.

BO'MBAZINE. (Βομβυξ, *a silk worm.*) A fabric of which the warp is silk and the weft (or shoot) worsted. It is chiefly made in black, and as an article of mourning for female dress. The capital employed in Norwich, during the most flourishing period of the bombazine trade, amounted to 300,000*l.*, but at present it is below 100,000*l.*

BOMB VESSEL. A ship of war, intended for the bombardment of a town or place situated on the sea coast. They are of about 350 tons burthen, and carry one 13-inch and one 10-inch mortar, together with two 6-pounder guns, one 12-pounder, and eight 24-pounder carronades, having a crew of sixty-seven men, with the usual complement of officers, and a detachment of marine artillerymen for the purpose of working the guns. See *Spearman's British Gunner*.

BO'MBIC ACID. The acid contained in the silkworm, especially in its chrysalis state. It is supposed to resemble formic acid.

BO'MBYCI'LLA. A genus of omnivorous Passerine birds, of which the Bohemian wax-wing (*Bombycilla garrula*) is an example, and an occasional winter visitor of Britain.

BOMBY'LIUS. A Linnæan genus of Dipterous insects, and now the type of a family (*Bombyliidæ*), characterized by the great length of the oral instruments, which form a long and slender proboscis; body thick, short, hairy; thorax gibbous; wings extended horizontally; halteres exposed; antennæ short, approximate, composed of three joints, the last the longest, thickened and terminating obtusely; legs long and slender. The insects of this family have a rapid flight, and are very active; they subsist entirely on the nectar of flowers. They are of small size, and mostly exotic, affording types of many genera, of which only *Bombylius* proper and *Pthiria* afford British examples.

BO'MBYX. A Linnæan genus of Lepidopterous insects, now the type of a family (*Bombycidæ*), including many genera of nocturnal and post-meridian moths. These have been arranged under the following sub-families: — *Hepialidæ, Notodoxtidæ, Arctiidæ*, and *Bombycidæ* proper.

BONA DEA. In Roman Mythology, a goddess concerning whom a great diversity of opinion prevails, even among the writers of antiquity. On the authority of C. Labeo, she is represented by Macrobius, who treats at length upon her nature and worship, as synonimous with the Grecian Rhea or Cybele. The Bona Dea had two temples at Rome; but her rites were generally solemnised in the house of the consul or prætor. In the celebration of these rites only women participated, thereby indicating the peculiar chastity of the goddess. But a perusal of the ancient writers will convince the most sceptical that the exclusion of men from the solemnities of the Bona Dea was purely nominal, and that in the course of time the grossest licentiousness was practised during their celebration. (See *Cic: pro Milone: Juv. Sat.* VI.)

BONA'SSUS. *See* BISON.

BOND. (Sax. bonð.) In Architecture, the connection of one stone or brick with another by lapping them over each other in carrying up work, so that an inseparable mass of building may be formed, which could not be the case if every vertical joint was over that below it.

BOND. In Law, a deed whereby the obligor, or party binding himself, obliges himself, his heirs, executors, and administrators, to pay a certain sum of money, called the penalty, to another (the obligee) at a day appointed. There is a condition added, that if the obligor does some particular act the obligation shall be void, or else remain in full force. In case this condition is not performed, the bond becomes forfeited or absolute at law, and charges the obligor while living; and after

his death the obligation descends on the heir, who (in default of personal assets in the hands of the executor or administrator) is bound to disharge it, provided he have real assets by descent. The condition is usually (although not necessarily) included in the same deed, and at the foot of the obligation.

A bond without a condition is termed single (or *simplex obligatio*); and it becomes single by forfeiture, on non-performance of the condition. At law, the whole penalty mentioned in the bond was recoverable on such non-performance. But by the interposition of equity the obligee was discharged from paying more than the sum to which the obligor was reasonably entitled: viz. his principal, interest, and expenses, if the bond was for payment of a debt; or the damages accruing to him, if it was for the performance of a stipulated act. But by 4 & 5 Ann. c. 16. it was enacted that in case of a bond conditioned for payment of money, the payment of the sum due, with interest and costs, even though the bond be forfeited, and suit commenced thereon, shall be a full satisfaction and discharge; and on this footing the law now stands.

A bond on which neither principal nor interest has been demanded for twenty years will be presumed to have been satisfied; but length of time is not, strictly, a legal bar, but only a ground for the jury to presume satisfaction.

In a bond where several are bound severally, the obligee may, at his election, sue all the obligors together, or all of them apart, and have several judgments and executions: but he shall have satisfaction but once; for if it be by one only, that is sufficient to discharge the debt.

Bond, English. In Architecture, that disposition of bricks in a wall wherein the courses are alternately composed of *headers*, or bricks laid with their heads or ends towards the faces of the wall, and in the superior and inferior courses of *stretchers* or bricks, with their lengths parallel to the faces of the walls, as in the margin, in which the upper is called the heading, and the lower the stretching course.

Bond, Flemish. In Architecture, that disposition of bricks in a wall wherein each course has headers and stretchers alternately, as in the margin.

Bond or Lap of a Slate. In Architecture, the distance between the nail of the under slate and the lower edge of the upper slate.

BOND STONE. In Architecture, a stone running through the whole thickness of a wall at right angles to its face, for the purpose of binding the wall together in the direction of its thickness.

BOND TIMBER. In Architecture, timber worked in with a wall as it is carried up, for the purpose of tying it together in a longitudinal direction while the work is setting.

BONE. An important organ in the higher orders of animals (*see* Anatomy), forming the solid support of their fabric, and protecting the vital organs, such as the brain and the heart and lungs, from external pressure and injury. In the human skeleton there are commonly enumerated 260 distinct bones. They, however, admit of classification under three heads; namely, *long* or *cylindrical* bones, such as those of the extremities; *broad* and *flat* bones, such as those of the skull; and *short*, *square*, *irregular*, or *solid* bones, such as the vertebræ, and those of the wrist and instep, and the patella or knee-pan: the first bones are generally filled with marrow, and are admirable specimens of strength of structure with the least possible weight. The bones are covered by a membrane called *periosteum*, by which the ramifications of blood-vessels and nerves pass into the bone. In the growth of a bone, the gelatinous or cartilaginous portion, as it has sometimes been called, is first formed, and the earthy or indurating part is afterwards deposited. We are indebted to Mr. Hatchett for our principal information respecting the proximate chemical components of bone. (*Phil. Trans.* 1799 and 1800.) The soft parts consist of gelatine and albumen; and the hard portion is composed of phosphate of lime and carbonate of lime, with small quantities of other salts. The animal matter of bones amounts on an average to about half their weight, or, when dried, to between 30 and 40 *per cent.;* so that they contain a large relative proportion of nutritive matter. The bones, including their animal matter, are the most durable parts of the animal fabric; hence the proposal of storing them up, as occasional sources of nutriment; for not only is the cartilaginous portion unimpaired, in bones which have been kept dry for many years, but it has even been found perfect in bones of apparently antediluvian origin. The best mode of extracting the nutritious part of bone for human food consists in grinding it fine, and subjecting it with water to a heat of about 220° in a digester; or the earthy part may be removed by dilute muriatic acid. When dogs and some other animals devour bones, the nutritive part is abstracted by their gastric juice, and the earthy part is voided in their excrement, forming what was formerly called *album græcum.*

When bones are submitted to destructive distillation, the gelatine and albumen which they contain is abundantly productive of *ammonia;* hence a copious source of that alkali and its compounds; the residue is a mixture of the earthy part of the bone with charcoal, commonly termed *ivory* or *bone black.*

BONE DUST, or ground bones, has recently been used with the best effect as a *manure.* It is usually applied to light or turnip soils, which it has rendered in no ordinary degree productive. For further details on this curious and interesting subject, see article "Agriculture" in *M'Culloch's Statistics.* The importation of bones from distant countries to be used as manure is now carried on to a great extent.

BONE EARTH. The residue of bones which have been calcined so as to destroy the animal matter and carbon, and become converted into a white porous and friable substance, composed chiefly of phosphate of lime. According to Berzelius, 100 parts of human bones are composed of 51·04 phosphate of lime, 11·30 carbonate of lime, 2 fluoride of calcium, 1·20 soda and chloride of sodium, 1·16 phosphate of magnesia, and 33. 30 animal matter. Albumen, gelatine, and fat constitute the animal part of bone, the greater part of which remains in the form of a tough cartilage when bones are steeped in dilute muriatic acid.

BONI'TO. The name of a species of Scomberoid fishes (*Thynnus pelamis*, Cuv.), common in the tropical ocean, and well known to voyagers from its persecution of the flying-fish (*Exocœtus volitans*), and flying squid (*Loligo sagittata*).

BO'NZES. The priests of the religion of Fo are so called by Europeans; especially in China, the Birman Empire, Japan, and other districts of Eastern Asia.

BO'OBY. The English name of a genus of *Pelecanidæ;* they are also called gannets, noddies, and soland geese.

BOOK. (Ger. buch.) "The general name of almost every literary composition, but in a more limited sense applied only to such compositions as are large enough to form a volume." Short and fugitive pieces are denominated pamphlets, in contradistinction to books, which are of greater length, and embrace more general or permanent topics. To the various sizes and forms in which books appear appropriate appellations have been given; as folio, quarto, octavo, duodecimo, &c. The materials of which books have been composed have been extremely different in different nations, and in different periods of the progress of civilization. Plates of lead and copper, bricks, stone, and wood were anciently employed for this purpose. At a later period the bark of trees formed the chief material in the composition of books, as is indicated by the original signification of the term *book* itself, and its equivalent in some some other languages. The materials of books were afterwards derived from the Egyptian plant papyrus; but as the demand for books increased, more durable materials were sought for, and leather, made chiefly from the skins of goats or sheep, was employed for this purpose. Next followed the use of parchment, on which the ancient MSS. were chiefly written: but all these systems were swallowed up by the invention of paper (*quod vide*), which took place about the 13th century, and facilitated the circulation of knowledge to an incalculable extent. The first books were in the form of blocks and tablets; but when flexible materials came into use, it was found more convenient to roll them up in scrolls, called by the Greeks *κόνταξ*, and by the Romans *volumen.*

BOOK-KEEPING. In Commerce, the art of recording, in a regular, concise, and systematic manner, the transactions of merchants, traders, or other persons engaged in pursuits connected with money. It has not only the authority of experience to recommend it, but that of some of the sagest observers of human affairs; Dr. Johnson remarks, "that the counting-house of an accomplished merchant is a school of method, where the great science may be learned of ranging particulars under generals, of bringing the different parts of a transaction together, and of showing at one view a long series of dealing and exchange. Let no man (the Doctor adds) venture into large business while he is ignorant of the method of regulating books; never let him imagine that any degree of natural abilities will enable him to supply this deficiency, or preserve a multiplicity of affairs from inextricable confusion." There are two modes of keeping books of account; the one by what is termed *Single* and the other by *Double Entry.* Both are in very general use. The system of single entry is chiefly confined to the business of retail-dealers; it is much the simplest method of book-keeping, consisting only of a day-book and a ledger. In the day-book the dealer enters his sales and purchases, and in his ledger he carries the former to the debit of his customers, and the latter to the credit of the merchants who supply him with goods. By making at any time a list of the sums due to him by his customers,

and of those due by him to wholesale merchants, the retail dealer may, after adding to the debts due to him the value of his stock on hand, arrive at an approximation to the real state of his debts and assets. This, however, is but an imperfect and unsatisfactory mode of book-keeping; and, therefore, in the case of wholesale and mercantile business, where extensive and multifarious transactions have to be recorded, recourse is had to the system of *double entry*. This system possesses all the advantages of single entry, besides being so complete and comprehensive in its principles, and so certain in its results, as to admit of universal application. It may with equal advantage be adopted in the most limited as well as in the most extensive, in the most plain and simple as well as the most intricate and complicated concerns.

No very authentic accounts exist of the origin of book-keeping. The double entry system appears to have been first practised towards the latter part of the fifteenth century, in Venice and other towns in Italy, then the great emporium of the mercantile world, and from this circumstance it acquired the name of the *Italian method of book-keeping*. The advantages of the system, and the soundness of the principles on which it is based, soon became apparent; for we find it was adopted in England and France early in the sixteenth century, and has continued to be more and more practised down to the present day.

The great objects of a good method of book-keeping are to exhibit transactions as they occur, in the most minute detail, and ultimately in the most condensed form; advancing from the earliest stage to the latest by such clear and lucid steps as at all times to admit of every fact being traced in its progress, and security being obtained at every step against omission or error. For the attainment of such important objects, no mode of book-keeping has hitherto been devised at all approaching to the perfection of the Italian system by double entry. Every transaction in business is twofold; there can be no receipt without a payment, and no purchase without a sale, and consequently by presenting the same event or fact on both sides of the books, whence the name of double entry, the entries being simultaneous, become corroborative of each other. The circumstance of every transaction being entered on both sides of the ledger affords one of the most valuable results derived from the system of double entry, namely, a test of accuracy; inasmuch as the entries on the credit side must be equal to the entries on the debit side, otherwise the books will not balance.

The three principal books required under the Italian system of double entry are, a cash book, journal, and ledger. In the first of these every transaction is recorded where money forms one of its elements, and in practice these transactions are by some book-keepers carried direct from the cash book to the ledger without being passed through the journal at all. The journal, however, forms a most important part of the system. It exhibits a narrative of every transaction of which an actual transfer of money does not form one of the elements, arranging the facts in as simple and condensed a form as correctness and intelligibility will admit of, and the results of those entries in the journal are afterwards introduced into the ledger, which thereby becomes a sort of key to the detailed history of every transaction; whilst at the same time it furnishes a luminous compendium of the whole. In like manner when the cash transactions are passed through the journal they are at stated periods classed and arranged in a condensed form, and thence transferred to the ledger. This plan of introducing the cash transactions into the journal is considered much the best system, though attended with a little more trouble to the book-keeper, as it affords great facilities in balancing the books and testing the accuracy of the ledger, more particularly when the recent improvements upon the form of the journal, which were originally suggested by the late Mr. Jones, are adopted. By the plan referred to, the journal is advantageously ruled with four cash columns, two upon the left hand side for *entries debtor*, and two upon the right for *entries creditor;* and all the transactions being connected either with *personal* and *property* accounts or *nominal* accounts, such as charges, profit and loss, and so forth, they are classed accordingly in the columns on the Dr. or Cr. side of the journal respectively; and as the debit entries are at all times equal to the credit entries, the aggregate of the two columns on the Dr. side must tally with the aggregate of the two on the Cr. side of the journal. This too is found in practice to be a most useful check against posting the entries to wrong accounts in the ledger; for on balancing the books, by taking the amounts Dr. and Cr. posted to personal and property accounts, and the amounts Dr. and Cr. posted to nominal accounts in the ledger, and comparing them with the total amounts in the corresponding columns of the journal, it will be seen whether they agree: if they do not, it demonstrates that some entries must have been erroneously posted, which can then only be discovered by collating the books; but if the amounts do agree, then it affords at least strong presumptive evidence that the whole of the entries have been carried to the proper accounts. Experience and practice are occasionally suggesting minor improvements upon the forms of the cash book, journal, and ledger, to suit particular cases, as well as upon the subsidiary books required for gathering together the facts preparatory to their being transferred in a condensed form into the journal; and indeed an intelligent book-keeper may accomplish much by a judicious classification of the facts in the auxiliary books; but the fundamental principles of the Italian system of book-keeping, notwithstanding such occasional facilities and improved arrangements in the working of it, remain perfect and unchanged; and after the length of time they have successfully withstood all attempts at innovation or change, it may safely be affirmed that the system is the best hitherto discovered, and is deserving of the utmost confidence and general adoption.

We have already stated that the Italian system of book-keeping admits of universal application; and we may now observe that it is not confined to merchants' accounts, but is equally applicable to government accounts. In evidence of its being so, we may instance the East India Company, where the double entry system is used with the most perfect success in all the branches of that great and well-conducted establishment, financial as well as commercial. One great desideratum in a system of book-keeping for government accounts is centralization, which can alone be attained by a proper and well organized method of condensing the facts or elements of the accounts; and the Italian system unquestionably affords the most efficacious means of collecting and grouping the widely scattered elements of government accounts in a concise and intelligible shape, and ultimately exhibiting them in the clearest and most perfect state of centralization admitted of. Several of the ablest ministers of France from the days of Sully downwards, convinced of the necessity of a good system of book-keeping in the management of the public money, and satisfied of the efficiency and soundness of the principles of the Italian method, successively attempted to get the government accounts kept on that system. But it was not till the present century that it was successfully introduced. It has since, however, fully realized all that was anticipated of it by those great men; and has been found to answer so completely that it has been universally adopted in all the different departments of the state. Equally beneficial effects have resulted from the adaptation of the system to the public accounts in Holland, and confirmed the advantage of its application to government business. Similar laudable attempts have been more recently made in this country by some of our ablest practical statesmen (among whom Sir Henry Parnell deserves particular notice), to introduce the Italian mode of book-keeping in the government offices; and from the signal success with which the experiment has been crowned, it is to be hoped that in a few years the whole of our public accounts will be placed on one uniform plan of book-keeping by double entry, and be thereby rendered as clear and intelligible as the accounts of any merchant in London, instead of being wrapped up, as formerly, in impenetrable obscurity and useless mystery.

BOOM. (Dutch boom, *a tree.*) A nautical term, signifying a long pole run out from any part of a ship to stretch the bottoms of particular sails; whence *jib-boom*, *main-boom*, *studdingsail-boom*, &c.

BOOM. In Marine Fortification, signifies a strong chain or cable stretched across the mouth of a harbour or river, to prevent the enemy's ships from entering, and having a number of poles, bars, &c. fastened to it; whence the name.

BOOPS. A genus of fishes of the order *Acanthopterygii:* most of them occur in the Mediterranean.

BOO'TES. (Gr. *βους, an ox.*) One of the constellations.

BORA'CIC ACID. See BORON.

BORACI'TE. Native borate of magnesia.

BORA'GINA'CEÆ. Plants resembling the genus Borago, after which they are named. They usually have a mucilaginous sap, in which nitre exists in small quantities; wherefore they decrepitate when thrown upon the fire. It is found that liquor into which borago itself is plunged when fresh becomes cooled, and hence the *Borago officinalis* was the principal ingredient in what was called a "cool tankard." Boraginaceous plants have usually pretty, and sometimes very handsome flowers, arranged in a gyrate manner. Forget-me-not (*Myosotis*), Bugloss (*Echium*), *Anchusa*, and various species of *Lithospermum* are well-known favourites either among wild or cultivated plants. Most of them have their leaves covered with asperities, whence their old name of *Asperifoliæ;* and some, as *Anchusa tinctoria*, *Lithospermum tinctorium*, and several others, yield a deep purple dye from their roots.

BORA'SSUS. (*Βορασσος, the skin of the date.*) A genus of palm trees, usually called fan palms, because their gigantic leaves are formed of plates radiating from the

top of the petiole, and folded up after the manner of a lady's fan. *Borassus flabilliformis* is an Indian species, with a trunk from thirty to fifty feet high, and leaves with from seventy to eighty rays. The Hindoos consider it the king of trees. A most intoxicating liquor is obtained by fermenting its sap, which is also capable of yielding sugar in considerable quantity under proper management.

BORA'TES. Salts of the boracic acid.

BORAX. This salt is found native in some of the lakes of Thibet and Persia, and is imported from India under the name of *tincal*, which after purification forms the *refined borax* of commerce. Of late years borax has been obtained by combining *native boracic acid* with soda. Borax forms hexædral prisms, slightly efflorescent, and requiring 20 of cold and 6 of boiling water for solution. When heated, water of crystallization is driven off, and the residuary salt fuses into what is called *glass of borax*.

Crystallized borax consists of 68 boracic acid + 32 soda + 90 water. It has upon some tests an alkaline reaction, and has hence been called *sub-borate of soda*. Borax is chiefly used by workers in metals as a flux: it is also employed in medicine.

BO'RDER. In Gardening, a marginal space, always connected with a walk or some other object, to which it forms an accompaniment.

BORDER, or BORDURE. In Heraldry, according to French heralds, an honourable ordinary, which should occupy a third part of the shield. In English blazonry, it has generally been considered as a mark of difference to distinguish one branch of a family from another. It surrounds the field, is of equal breadth in every part, and occupies one fifth of the field. When there is a chief on the coat, the bordure is supposed to run under the chief; but it passes over other ordinaries, as a fess, &c.

BORE. A word used to express the sudden rise of the tide in certain estuaries.

BO'REAS. In Grecian Mythology, the son of Astræus and Aurora, and usually worshipped as the god of the north wind. There are few of the minor Grecian divinities of whom so strange and multifarious exploits are recorded as of Boreas; and it is interesting to trace to its source the allegory of all his adventures and achievements, and thence to elucidate the causes of his deification. The assiduity, for instance, with which the worship of Boreas was cultivated at Athens proceeded from gratitude, the north wind having on one occasion destroyed the fleet of the Persians when meditating the invasion of Attica. A similar cause induced the inhabitants of Megalopolis to consider Boreas as their guardian divinity, in whose honour they instituted an annual festival. With his usual partiality for mythological allusion, Milton has given Boreas a place in his *Paradise Lost*: —

> Now from the north
> Of Norumbega, and the Samoed shore,
> Bursting their brazen dungeon, armed with ice
> And snow, and hail, and stormy gust and flaw,
> Boreas and Cæcias and Argestes loud,
> And Thrascias rend the woods and seas upturn.

Boreas was usually represented with the feet of a serpent, his wings dripping with golden dew-drops, and the train of his garment sweeping along the ground.

BO'RON. The base of boracic acid, discovered by Davy in 1807. It may be procured by heating dry boracic acid with potassium. It is a dark olive-coloured substance, a nonconductor of electricity, insoluble in water, infusible, and of a specific gravity = 2. Heated to redness it burns into *boracic acid*, which consists of 20 boron + 48 oxygen.

Boracic acid is found in the hot springs, and amongst the volcanic products of the Lipari islands, and in the waters of Sasso in the Florentine territory; it also occurs in some minerals. It may be obtained by adding excess of sulphuric acid to a strong solution of borax. Its specific gravity is 1·48. In its usual state of scaly crystals it is a *hydrate*, composed of 68 dry acid + 27 water. In this state it requires about 30 parts of cold and 3 of boiling water for its solution. It dissolves in alcohol, and the solution burns with a characteristic green flame. It reddens litmus; but renders turmeric brown, like an alkali. When its water is driven off by fusing it at a high heat, the anhydrous acid concretes into a glassy substance of the specific gravity of 1·8. It is a useful flux, and was formerly used in medicine under the name of *Homberg's sedative salt*.

BO'ROUGH. A town possessed of certain municipal institutions, of which the name is derived by some from the Saxon word burg, meaning an inclosed place; by others from another word of the same language — borg, meaning pledge, which was applied to some of the associations for mutual liability established by the Saxon law. Boroughs, in the sense of the definition above given, must have, in some shape, existed very early in this as well as in other countries; but the origin as well in constitution as in name of the existing municipal system in England can be traced no higher than Saxon times, and the general and connected history of English boroughs does not begin before the Conquest.

According to Doomsday Book there were in England at that time eighty-two boroughs, including cities, differing considerably in the extent of their franchises as well as in their customs and mode of government; but agreeing in this general character, that they were communities established chiefly for the purposes of trade, endowed to that effect with certain franchises, such as that of a fair or market, and possessing as boroughs a special jurisdiction exercised in the the borough court-leet, and exclusive of the jurisdiction of the hundred, with which in the political scale a borough was co-equal. Some of them then held, and all were capable of holding, lands in common; and in respect of such land they held, as did also each burgess in respect of his own tenement, of some lord, by a species of tenure called burgage tenure, which was in fact only the ancient tenure in common socage, *i.e.* tenure by rent or service certain, which continued to prevail in boroughs after the general imposition upon other lands of the feudal or military service. The lordship of the land of the borough, and of the different tenements which it contained, must have belonged in the first instance to the lord of the manor within which it was situate; but all boroughs, in contemplation of law, held their franchises of the king.

Great obscurity prevails as to what was originally the internal constitution of boroughs, and as to how far it was popular or not, and how far also it was or was not uniform. It is certain that as early as the date of Doomsday Book the proportion between the number of burgesses and that of other inhabitants was very different in different boroughs; though the fact may be reconciled with the notion of a system originally popular (which has all along prevailed in some boroughs), upon the supposition that the franchise had either been usurped on the one hand, as has frequently happened in the case of larger communities, or abandoned on the other hand as of little value, on account of the liability that attached to it of contributing to the common charges. Much perplexity also arises on this subject from the intermixture in the same place of the guild and borough franchises (*see* GUILD), which prevailed to that extent that the guild-merchant, which appears to have been an incorporation, or an association by licence of all trades within the borough, is by some considered as identical in its constitution with the borough itself; and it is certain, at any rate, that the guild-merchant, though it did not in the first instance constitute the borough, yet in many places usurped its franchises and government, and finally assumed its name; so that, with the exception of burgage tenure, which still prevailed in some few places, and of birth, which was common to both institutions, the other modes of obtaining the freedom of a borough,—*i. e.* those of apprenticeship, purchase, or gift,—were introduced into the municipal system from the guild-merchant. Distinct from this in their relations and contests with the community of the borough at large were the guilds of particular trades, which succeeded in London in engrossing and parcelling among themselves, under the name of liveries, the whole of the municipal franchises.

All borough rights, being exceptive, rested either upon charter, or upon prescription, which supposes a charter. Some few of such charters were granted by Saxon kings: but they became much more frequent after the Conquest, the style and purport of these early documents being simply that of a grant to the *men* and *burgesses* of such a place of certain franchises, whether relating to trade, as that of a fair or market, or exemption from toll, or to jurisdiction, such as a commission of the peace and the right of holding sessions, which was first granted to any borough by Richard II. In the reign of Henry VI., a remarkable alteration took place in the style of these royal grants, it being then first that were granted, as it is said, charters of incorporation, strictly so called; though previous to that time boroughs, or the governing bodies that represented them, enjoyed all the privileges of a corporation, and since that time many have continued to enjoy them without any such special grant. From that time forth, however, the history of boroughs becomes identical, except as to the parliamentary franchise, with that of municipal corporations. These charters of incorporation did not, any more than did those which preceded them, pretend to regulate the internal constitution of boroughs. This very generally assumed the form of a government by a small and in great measure self-elected body, which had in most cases succeeded in engrossing not only the whole administration, and in a great degree the enjoyment also of the borough franchises and property, but the right also of granting, according to rules more or less arbitrary, admission into the subordinate body of burgesses or freemen. And even that body, where it existed, which was not always the case, was small in proportion to the whole number of inhabitants. It was the great object of the charters granted by the Tudor sovereigns to sanction and confirm the usurpations, if such they were, of these municipal oligarchies, with the view apparently of throwing the representation of boroughs (a right which had been conferred in the first

instance by Edward I., had since been extended by fresh grants, and was then becoming of considerable importance) into the hands of such as were most likely to be easily guided or controlled, either by the crown itself or by the great lords upon whose support it reckoned, and with whom it became usual about the same time to connect themselves with the boroughs in the neighbourhood of their possessions, under the honorary title of high stewards. The exclusive system of municipal government, which attained its height during the Stuart dynasty, continued unimpaired till the present time, when it was effectually put an end to by the Act for the Regulation of Municipal Corporations, passed in the year 1835. For an account of which, as well as of the other remarkable incidents in the history of our municipal institutions, which happened from the time of the Tudors to the present period, see title MUNICIPAL CORPORATIONS; and for an account of the *representation* of boroughs, and particularly of the *reform* in *their representation*, see title PARLIAMENT.

The account above given of English boroughs, both as to their origin and constitution, applies in all its general features to Scotch boroughs; with this qualification, that the government by close corporations was in the latter country more thoroughly and more generally prevalent until the reform in them, which preceded by a year the Municipal Regulation Bill applicable to this country; and resembled it in almost every thing but this, that it made the qualification for burgesship identical with that required to give a vote in the election of members, namely, the occcupancy of a house of the yearly value of 10*l*.

In Ireland the municipal system, as it now exists, is of considerably later origin than in Scotland or in England. It was transplanted, and gradually introduced from the latter country; and though with the same names and form of constitution as then existed there, had much more in it of a political character, being intended in the first instance as a support to the English against the Irish, and in later times to the Protestant against the Catholic, and was so used to the neglect of functions more properly municipal, which have therefore in many instances been intrusted to other hands by local acts of parliament. These distinctions of religion and birth aggravated also in other respects the vices of a close and exclusive system, which was there, as in Scotland, more generally and thoroughly established than it ever was in this country. A measure for the reform or abolition of the existing municipal corporations of Ireland is now pending before the legislature.

BOROUGH ENGLISH. In Law, is a customary mode of descent of lands in some ancient boroughs and manors, by which estates descend to the owner's youngest son; or if he has no issue, to his younger brother. *See* DESCENT.

BOS. (Lat. bos, *an ox*.) A genus of ruminating mammals, which is one of the most important in relation to the necessities and conveniences of man. To this genus belongs the domestic ox, in all its various breeds and varieties. With respect to the wild original of our numerous herds there is yet some obscurity; less, however, than hangs over the origin of other domesticated species. The wild cattle which approach nearest to the tame are those which inhabit the forests of the north-east of Europe; and the white cattle, which are still preserved in a state of purity at Craven, at Chillingham Park, and in Scotland. These are both referred to the species called *Bos taurus*, or *Bos urus*, or *Urus Scoticus*; but there is much reason for supposing this species to have been the domestic ox reverted to a state of nature. Another well-marked variety of this species is the Brahminy bull; characterised by the hump on the shoulders and the pendent dewlap.

The other known wild species of ox are the Gayal of India (*Bos gavæus*); the Yak of the mountains of Central Asia (*Bos grunniens*); lastly, there are the Buffaloes, which, though anatomically less distinct than the Bisons from the typical *Boves*, yet differ from the oxen as a group in many points. They have larger horns, which sometimes form a horny covering of great thickness to the whole frontal region; and they approach the Pachydermata in the thickness of the skin and the thinly scattered coarse hair. They frequent marshy grounds, and feed on a ranker and coarser herbage than the ox. The flesh of buffaloes is rank and coarse, and they are used chiefly as beasts of draught or burden. The two best marked species are the Indian or Arnee buffalo (*Bos arnee*), and the South African buffalo (*Bos caffer*).

BO'SSAGE. (French.) In Architecture, any projection left unwrought on the face of a stone for the purpose of afterwards sculpturing thereon, the sculpture being usually the last thing finished.

BO'STRICHUS. A genus of Coleopterous, Xylophagous, or wood-boring insects, now raised to the rank of a family (*Bostrichidæ*), including amongst its numerous genera three which contain species whose ravages have called forth the attention of the legislature both in this and other countries in consequence of the extensive destruction of valuable timber caused thereby. The species in question are the *Bostrichus ligniperda*, *Scolyttus destructor*, and *Tomicus typographus*; but the two latter are the most mischievous, and astonish by the amount of damage which is produced by insects of so small a size. The elm tree is the object of attack to the *S. destructor*; while the *T. typographicus* restricts its operations to the fir. The females attack the crevices of the bark, and perforate it in diverging lateral channels, in which from sixty to eighty eggs are deposited. At the end of fifteen days the larvæ are hatched, and forthwith commence the work of destruction, each gnawing a serpentine gallery between the bark and the wood, and gradually enlarging its burrow until the period when it is ready to pass into the pupa state; when, having finally become a perfect beetle, it directly bores through the portion of the tree which remains between the wood and the outer bark, and escapes through a small circular aperture in the latter. This emergence of the perfect insect takes place in the month of May; and in seasons favourable to their development they appear in swarms, and rise to a height exceeding that of the trees, and may be carried by the wind to another and distant part of the forest. The impregnation of the female takes place in the air; so that wherever they alight they are ready to recommence the work of destruction. The chief precautions and remedies which experience has suggested are to cut down the trees which are once attacked, immediately to bark them and to burn the bark, and to remove all felled timber without delay.

BOSWE'LLIA. A genus of Indian trees belonging to the natural order *Burseraceæ*, one species of which, *B. thurifera*, yields the resin called Olibanum, which seems to be a corruption of Luban, the name given by the Hindoos to this plant.

BOT. The name of the larvæ of the Dipterous insects of the family *Œstridæ* (which see).

BO'TANY. (Gr. *βοτανη*, *herb* or *grass*.) That branch of natural history which relates to the vegetable kingdom; not merely including the nomenclature and classification of plants, as some have supposed, but embracing all the phenomena of vegetable life in their widest extent.

Looking only at the first principles of the science, it is generally divided into the following heads:—

Organography, or the Structure (organization) of Plants.— This is a most important department; it comprehends whatever relates to the various forms of tissue of which plants are anatomically constructed; it explains the exact organization of all those parts through which the vital functions are performed; and it also teaches the relation that one part bears to another, with the dependence of the whole upon the common system. Without a perfect knowledge of Organography no systematical arrangement can be understood; for, being that part of science in which the laws of the symmetry of parts is comprehended, it must necessarily be the basis of all theory of classifications: and as to Descriptive Botany, which may be called the language of the science, it cannot have any logical precision, or be intelligible, unless the mind is distinctly impressed with the fundamental laws of this branch of study. Physiology itself, the highest branch all natural science, depends so absolutely upon an exact knowledge of the structure of parts, that any attempt to investigate the important laws of vegetable life must necessarily be abortive without a strict acquaintance with the more important details of organization. And by this is not meant merely a general idea of external form, or a vague notion of internal anatomy, but the most precise knowledge that the nature of the subject will admit.

Connected with this branch of study is what German botanists call Morphology, but which others think it better to consider a section of Organography. The word Morphology signifies literally the "science of changes or transformations." As applied to botany, it embraces a very interesting subject of inquiry, and one which, to all those who know the importance that attaches to comparative anatomy in the animal kingdom, cannot fail to be peculiarly interesting. Within the last thirty or forty years it has been clearly made out that all those parts which are familiarly known under the name of leaves, flowers, and fruit, are constructed, in all cases whatsoever, upon a simple uniform plan, out of one single organ in different states of modification and combination; and that there is no other difference between the flower of a rose and that of a nettle than what arises from modifications and combinations of this organ — which is the leaf. If it be doubted whether, considering the anomalous character of some of the lower orders of plants, all vegetables are without exception formed upon one and the same plan, it is impossible not to admit that, at least in all Phœnogamous plants, the flowers are composed of the same elements; that these elements are arranged in conformity to a few simple laws, far less variable than their appearance seems to indicate, and the study of which constitutes the basis of the theory of botany. These laws are so evident in a great number of cases, that one scarcely pays attention

to them; but curiosity is at once excited when they seem to be violated. Exact observation, however, shows that in such cases they are only masked; that is to say, an unusual application of two or three different laws produces an apparent anomaly, which is easily explained by a reference to the numerous cases of degeneracy, abortion, and cohesion with which the vegetable kingdom abounds. In such instances as this the botanist may be compared to the mineralogist, who discovers the primitive forms of crystals by means of their secondary forms. We are so accustomed to talk of plants bearing leaves and flowers and fruit, and it is so evident to our senses that extremely different organs really do exist under such names, that it seems inconceivable that parts so very dissimilar should all be only leaves in different states; that the pure white petals of the lily, the rich red flowers of the rose, the sweet-smelling blossoms of the jasmine and the orange, or the long trumpet-shaped corollas of the honeysuckle, should all be leaves; that the stamens in which the fertilizing powder is locked up, the pistils which are destined to receive the influence of the pollen, the ovula that they contain, and, finally, that the fruit which is the result of the action of the two last, are all so many parts formed out of one common organ, which in a particular and very frequent state is what we call a leaf. Botanists do not mean to say that he who eats an apple, or an orange, or a peach, is in a state of mental delusion, and that while he fancies himself to be enjoying the pleasure of gratifying his palate by the most delicious flavours he is really only chewing the leaves of these plants; but they assert that those appendages of a plant which are commonly called the leaves have a peculiar anatomical structure, and a certain relation to the stem on which they are borne, and being developed according to certain fixed laws, are always arranged upon a certain and uniform plan with respect to each other; and that all the other organs, whether calyx, corolla, stamens, pistils, or fruit, have an anatomical structure essentially the same, bear the same relation to the axis that they grow upon, are developed according to the same laws, are arranged upon the same certain and uniform plan with respect to each other, and, finally, are constantly becoming transformed into leaves of the ordinary appearance, thus losing the condition in which they are usually found, and reverting to their structural type. The admission of such propositions as these does not render our notions of the distinctions between the various organs more obscure than it was before, as some would assert; but on the contrary it enables us the better to understand the real nature of the organization of any part, and the plan upon which the most complicated arrangements of these organs have been effected. For example, who is to explain how it happens that buds occasionally spring from the axillæ of petals or sepals, that anthers are found having ovules, that branches push forth from the centre of pistils, that petals become antheriferous and stamens petaloid, unless the proposition is admitted that all those apparently different parts are formed upon a common plan, the type of which is a leaf, and are all therefore convertible into each other?

Another branch into which the science separates is *Physiology*, or the department which treats of the vital actions of plants. While organography is applicable to objects whether living or dead, physiology solely refers to them in a state of vitality. There is scarcely any part of natural history more difficult than this, if rigorous demonstration is required, nor, at the same time, one upon which there was in former days a greater degree of mere speculation. Like many other of the higher departments of natural philosophy, hypothesis preceded experiment; so that in the earlier history of botany we find scarcely a trace of those ideas which modern observation has certainly developed in a very remarkable manner.

In vegetable physiology it is not as in animal — we have not our highest order of beings endued with reason which we can study by aid of our own personal feelings and sensations, and from our knowledge of which we can proceed in a descending series to the determination of the vital functions of all other tribes. On the contrary, we are in the same position with regard to plants as a new and totally distinct race of animated beings would be to mollusca and the lowest orders of existing things, supposing such a race to have no knowledge whatever of animal economy beyond what could be learned from the study of mollusca themselves, to have a class of sensations and a structure wholly unlike our own, and finally to deduce its notions of the anatomy and vital system of mollusca, not from a comparison of them with other beings gradually and perhaps insensibly rising in perfection of organization till the relation of one part to another and the uses of all become more manifest, but wholly from the abstract consideration of the mollusca themselves. In such a case, speculation would most likely precede experimental observation, as was actually the case with plants.

It was not till after the invention of the microscope that even an imperfect knowledge of vegetable anatomy could be gained; and only when this great step was taken vegetable physiology began to establish itself upon a sure foundation. Consequent upon this discovery has been the accumulation of a considerable amount of positive knowledge of a world of organized beings having nothing in common with the race of man; with which we cannot communicate in the slightest degree; that have no volition by which we may occasionally regulate our judgment; whose texture is so frail that we cannot anatomise them without the destruction of life; whose functions are performed within an opaque dense covering that excludes every thing from our view; and which finally are so exceedingly simple in their organization, have so few different organs with which to execute their functions, that we are lost in amazement at effects so complicated and forms so various being brought about by means that are seemingly so inadequate. The world has learned from the vegetable physiologist, not only that plants breathe, feed, and digest, and how the functions of breathing, feeding, and digesting are carried on; they have ascertained by what means an increase in their dimensions are brought about, how their want of locomotive power is compensated for, and by what precise means their reproduction and multiplication are so wisely ordained as to be placed beyond obstruction by any natural impediments. In short, the exact use of every part of every plant, various as their forms and uses doubtless are, has been ascertained; and we are now entitled to say of plants as of animals, that their kingdom is rendered subject to the power, not only of man's physical energy, but of his mental resources. Perhaps no part of the creation illustrates more forcibly than the vegetable world, the admirable skill and foresight with which all the phenomena of the universe have been adapted by the Great Author of our being to the accomplishment of the objects for which they have been severally intended.

Take, for example, vegetable tissue. What can be conceived more wisely prepared! The cellular, capable of great extensibility, possessing also prodigious compressibility, its particles cohering either firmly or loosely according to circumstances, its sides composed of a most delicate membrane, through which fluid and gaseous matter passes readily in every direction, is destined to form the principal mass of the vegetable, and to execute all those functions with which absorption and respiration are connected; — the fibrous tissue, composed of myriads of threads compactly combined into bundles, dispersed through the cellular substance, how admirably does it supply the place of bones and nerves in the animal economy, affording strength and solidity and elasticity to the most delicate parts! While the vascular tissue, exclusively intended for the reception and rapid transmission of gaseous matter or of highly attenuated fluid from the roots to the extremities, how wisely is it contrived by its greater size and length, and how carefully is it prepared by its spiral structure, for extending and turning, as the cellular substance develops, to those parts where the peculiar matter that it contains is most required! Here there is no confusion of offices to perform; each has its peculiar part assigned it, for which it has been especially destined, and for which it is alone adapted.

Look at the leaves. The leaves are the organs in plants that correspond with the stomach in animals; that is to say, it is in them that the fluid matter taken up by the roots and injected into them from the stem, is digested and inspissated, and separated into the nutritious and excremental portions. To the naked eye the leaves appear to be merely flat plates of cellular substance traversed by veins; but examined with a microscope they are at once seen to be constructed upon a most simple plan — of any that can be conceived the most perfectly adapted to the end in view.

Digestion takes place in leaves chiefly by the absorption of carbonic acid and the respiration of oxygen, and by the evaporation of water; if this process were to be carried on without any provision against the variations which are constantly occurring in the state of the atmosphere, it is easy to conceive that in excessively dry weather leaves would lose all their moisture and constantly become parched up, while in wet weather they would be so gorged with moisture as to burst from distension. In order to prevent the occurrence of this, nature has enclosed leaves in a cuticle scarcely pervious either to air or moisture; and in this cuticle she has placed numerous mouths, called stomata, which have the power of opening and closing, according to the state of either the atmosphere or of the leaf itself, to regulate the absorption or respiration of either water or air. And in order to expose the tissue lying beneath this cuticle to the greatest possible atmospheric influence, the leaf is not a solid mass, as it appears to be, but is traversed in all directions by passages terminating in the mouths, and opening into cavities, where the air both of absorption and exhalation can freely circulate, and pass in or out so long as the mouths permit it. Nor is this all. Many leaves are constantly submerged beneath the surface of

water, where they are never exposed to atmospheric vicissitudes, can never evaporate, and being cut off from the air, can neither absorb carbonic acid from the air, nor discharge oxygen back into it in return. It is therefore obvious that the curious provision that has been made for the regulation of the action of aërial leaves would be useless in submersed ones; and accordingly we find that the latter have neither cuticle, nor mouths, nor cavernous parenchyma, but are thin but solid plates, the whole surface of whose cellular substance is in direct contact with the water, from the air contained in which the leaves must exclusively derive their nutriment. The employment of the same kind of organ, in different forms, for the purpose of effecting the varied objects that are to be provided for in the vegetable economy, is another and a most remarkable instance of the consummate wisdom and wonderful simplicity that are discoverable in all these things. Upon the birth of a plant one or two leaves are developed, which feed the infant until it is strong enough to develop one or two more; these last, not only like the first proceed without exception from opposite sides of the stem or body, but are so placed as to alternate with the first; and this goes on with unvarying uniformity, as long as growth continues; so that view a plant in whatever way you will, whether in its earliest state, or at the most advanced period of its existence, it will always be seen to exhibit the same beautiful symmetry as the most highly developed animals: one side counterpoises the other; whatever is discoverable on one side, equally exists upon the other. If it is necessary that a protection should be formed for securing the young and tender buds against cold, the leaves surrounding the buds suddenly contract into hard scales, perhaps exude some resinous or gummy matter, or clothe themselves in a deep covering of wool, and an impenetrable living shield is thus interposed between the bud and danger. A plant is to be rendered more beautiful to the eye — its leaves again contract, the spaces that usually separate them are obliterated, new colours are assumed, and petals are created resplendent with brilliant hues or exhaling the softest perfumes. Propagation is to be effected — the petals contract into stamens, their central substance becomes disintegrated in the form of pollen, and the interior of each grain of the latter is resolved into that living matter of which in a state of cohesion all nature is composed. A few leaves are rolled together in the form of pistillum, the apex of the midrib becomes denuded, and young buds are developed at the margins. A grain of pollen, the disintegrated tissue of the flowering leaf, falls upon the denuded apex of the fructifying leaf, absorbs moisture from it, distends, and finally produces a tube of inconceivable fineness, which abstracts from the pollen its impregnating matter, some of which descends the midrib into the womb of the leaf, and thence entering the young buds that are developed at its margins, is finally hatched, and appears at last in the form of embryo plants.

Such is the simplicity of the arrangements that are observable in the most perfectly formed, the most elaborately constructed plants. In the lower orders, the mode of formation, development, and propagation is still more simple. A vesicle elongates and distends until it becomes a tube; from the end of this tube more are generated that themselves give birth to others, and thus a simple branching plant is formed. In the inside of each tube by degrees a green matter is deposited; and after a certain period has elapsed is emitted in the form of little green vesicles, like that from which the plant originally sprang, and themselves capable of developing as new plants. In certain tubes, this dissolution takes place in a much more astonishing manner; not into inert green matter, but into moving particles having all the properties of spontaneous motion and animal existence. Soon, however, the moving particles elongate; thus losing their power of motion and becoming plants, to whose laws of life they ever after submit. Turpin has seen the *Monema comöides* resolve itself into naviculæ; Desmaziéres has shown the plants called *Mycodermata*, or what we name the mothery film of fermented liquor, to consist of monads growing end to end (*Ann. des Sc.* x.); and Treviranus (*Ann. des Sc.* x.) has detailed with exactness the metamorphoses in the life of the compound plant called *Batrachospermum glomeratum*. In this the filaments discharge a green matter and become colourless; the green matter consists of myriads of infusoriæ, of a round or elliptical figure; the latter collect by fives or sixes into a kind of star, become motionless, lengthen, and finally are transformed into young individuals of this undoubted plant.

These are far from being all the divisions into which Botany, or the study of the vegetable kingdom, may be subdivided; although they are no doubt among the most interesting. Besides these there is *Taxonomy*, or the principles of classification. It would be of little use that a man should know anatomy, and structure, and comparative organization, and have informed himself of all the leading principles of physiology, if he were unacquainted with the names of the objects he had been studying, and were consequently incapable of communicating his knowledge to others. At least, of whatever use it might be to himself, it could not be of advantage to any one else. But if he *is* acquainted with the names of known objects, and if he understands the rules of classification, he can then render his information available to others as well as to himself. And in like manner he can at all times determine what is known about any particular plant that he may have been studying; or if it be a kind previously unknown, he can find its place in the system, and by publishing a description of it, he can fix it there for the information of others.

But there is another way of looking at the utility of classification, which shows that what may to some appear but a dry and barren subject, is in reality one of the most important branches of the science. No man can know all things relating to such a science as this, — few men can learn many things; for this reason it is of importance that a means should be discovered of judging of what is unknown by what is known; and that by judiciously selecting a moderate number of objects for particular study, the inquirer may have a ready and by no means burthensome means of forming a clear knowledge of the whole vegetable kingdom. This is not difficult, if attention be paid to the doctrine of affinities. Every one must have seen that some species of plants are more like each other than they are like different species; without considering the matter botanically, every one must, for example, have remarked that a radish is more like a turnip than it is like a currant bush, that a pea is more like a bean than an apple, and that a cherry blossom is more like an apple blossom than a horse chesnut. These are rude instances of affinity on the one hand, and discrepancy on the other; but they are nevertheless perfectly explanatory of what is meant. Botanists find that classification may be founded upon a consideration of general resemblances and differences; and that by carefully examining the characteristic organs of plants, those species may be classed most nearly together which have the greatest degree of resemblance and the most perfect constitutional agreement. Now this being the case, it follows that a knowledge of one species is to a great extent a knowledge of many; and that a correct idea of a single individual of a group in the classification, provided that individual is well selected, amounts to a knowledge to a considerable extent of all the other species of the same group. For example, in the tribe of *Cruciferæ*, consisting of about 900 species, the study of the common radish, the mustard, or the cress, will give the student a very accurate general knowledge of the remaining 899, because they are all close modifications of the same forms. Again the common potatoe, rightly understood, represents the greater part of *Solanaceæ*, or at least of some hundred species belonging to that tribe; while the dead nettle, *Lamium album* or *rubrum*, stands as the representative of some 15 or 1600 species called *Labiatæ*. This would be of eminent importance if its advantage stopped here; but when it is considered that the properties of plants also accord in a very remarkable manner with their structure, and that those which are most closely approximated in a classification will most nearly resemble one another in their sensible properties, the advantages to be derived from a study of the laws of affinity cannot fail to be clearly perceived. For example, to use the same illustrations as before, any person acquainted with *Cruciferæ* would know that there is no instance of a poisonous or deleterious plant in the tribe, a point of great importance to be aware of; on the contrary, he would know that if they had succulent roots, they might be employed like the radish, and that their leaves are antiscorbutic; but if he met with an unknown plant, which, from its resemblance to the potatoe, he knew belonged to *Solanaceæ*, he would at once reject it as poisonous, or at least suspicious, unless it had tubers filled with fæcula, when he would except that portion, because all fæcula is wholesome, however poisonous the trees or plants may otherwise be that produce it, provided the deleterious matter that lies among it is removed by washing, or volatilized by the action of heat.

It is not, however, any kind of classification that leads to such ends. All artificial systems, as for instance that of Linnæus, are unproductive of such results. It is only the natural system of botany from which these important advantages are to be derived.

A fourth division of the science is the meaning of the terms employed in the science; or what was formerly called *Terminology*, and now more correctly *Glossology*. This is the least interesting part of the subject; but at the same time it is too important to be passed over lightly, because it is impossible either to understand the writings of botanists, or to make oneself intelligible to others, without being correctly informed of the meaning of the terms peculiar to the science. The state of Terminology at any given time may indeed be safely taken as indicative of the state of the whole science; for in propor-

tion as ideas are multiplied and knowledge rendered exact, are the terms required to express those ideas multiplied and their application rendered definite. A curious exemplification of this is to be found in the *Historia Plantarum* of Fuchs, a learned botanist of the 16th century. In the glossary prefixed to that work are comprehended only 132 terms of all kinds, many of which refer to measures, and are therefore not appertaining to botany; and of the remainder 29 belong to modifications of stems, 15 to differences of inflorescence, 6 to the fruit, but not one to any other part of the fructification. In the present state of botany, the terms that relate to the seed alone are probably as numerous as the whole that are comprehended in Fuchs' Glossology.

Another and very distinct branch of inquiry is into the rules to be observed in describing and naming plants; or what is called *Phytography*. The great object of descriptions in natural history is to enable any person to recognise a known species, after its station has been discovered by classification, and also to put those who may not have had the opportunity of examining a plant themselves into possession of all the facts necessary to acquire a just notion of its structure and affinities. It is therefore important that such descriptions should be drawn up according to certain conventional well-known rules, and not according to the caprice of individuals; and this not only for the sake of ensuring a uniformity of language, and in all cases the same order of treating the subject, but also to prevent descriptions being too general, to ensure attention to the most important points of structure, and at the same time to prevent their being more prolix than is really necessary. The rules of description are more especially intended to guard against the latter evil; for no mistake can be more common than to confound prolixity with precision.

The last branch into which the study of the science may be divided is the application of the preceding subjects to the art of discriminating species. This may be called the *Practice of Botany*, as the former belonged to its theory, and is by far the most difficult part of the subject. There is no difficulty in becoming acquainted with the fundamental principles of the science, because they naturally arise out of each other, and are dependent upon the just appreciation of a few simple laws; the various combinations of which, upon principles that it is easy to comprehend, constitute the differences that exist between organs themselves and their numerous modifications. But the practice of botany, although its study is essentially facilitated by an acquaintance with fundamental principles, and indeed cannot be usefully pursued without, yet it has peculiar difficulties of its own. It is often difficult to recognise organs in consequence of the manner in which they are masked by the modifications they have undergone; their combinations are frequently so intricate that great experience is necessary to enable an observer to judge of them correctly; their minuteness is often such as to render indispensable a use of the microscope, which requires peculiar dexterity and a good deal of practice; and finally the number of species is so great, that to bear in mind their distinctions is a heavy tax upon the memory. Difficulties of this nature are almost insurmountable by a student who is unaided by the experience of a teacher.

At what period of the world botany first began to be studied as a science, has not been satisfactorily ascertained. By some it has been referred to the highest ages of antiquity. We are assured that Moses and Solomon and other Jewish writers, especially the last, were botanists, and that traces of much knowledge of the science are to be found throughout the scriptures; but it seems difficult to assign Botany any such antiquity. That in the most remote ages man had his herbs and his roots; that he was acquainted with the properties of one plant, and the uses of another; that he gave them names, and that poets derived many of the beauties of their language from them, — was natural enough; but this had nothing to do with botany. The first dawn of that science broke from out of the deep investigations of the nature of matter and mind by the philosophers of Greece. How much they knew we have no accurate means of judging; but that they knew a great deal of vegetable physiology is obvious from their famous paradox, that plants are only inverted animals, — a sentiment which, however strangely it may sound, could only have arisen from an extensive knowledge of the vital phenomena of Vegetation. Nor could the doctrine of Aristotle, that all organic matter exhibits a series of successive degrees of development, have been conceived or promulgated, unless the philosophers of his day had possessed a practical acquaintance with vegetation much beyond that of the ages that succeeded.

Happy had it been for those ages if, instead of retrograding in the path of science, or rather stepping out of it altogether, they had only pursued the course commenced by Theophrastus 350 years before Christ. By that naturalist the beginning was made of applying particular terms to particular modifications of structure; he demonstrated the absence of all philosophical distinction between trees, shrubs, and herbs, — a distinction upon which his successors were fond of insisting; he speaks clearly of the parenchyma and woody fibre of wood, the former of which he calls the flesh; and he described accurately the difference between palm wood and that of trees with concentric layers; so that in point of fact the discovery of the difference between Dicotyledonous and Monocotyledonous wood was made by Theophrastus above 2000 years ago, although it was never applied to the purposes of systematic division till about thirty years since. Subsequently to this period, botanists almost disappeared for a long season. Those who have been dignified by historians with that title were either pharmacologists, like Dioscorides; or compilers, who, like Pliny, knew little themselves, and misunderstood those they copied; or *poets*, who drew much of the beauty of their language from the charms of nature; or *geoponical* writers, who were acquainted with those parts of husbandry which relate to physiological botany.

With whom the curious arts of budding and grafting, and striking plants by layers, or propagating them by taking advantage of the divisibility which distinguishes the vegetable from the animal kingdoms originated, is now unknown; but there is reason to believe that the greater part of the modifications of those processes was in the classical ages as well understood as now. That grafting was extensively undertaken, is obvious from these lines of a well-known poet of the Augustan age: —

> Et sæpe alterius ramos impunè videmus
> Vertere alterius, mutataq. insita mala
> Ferre pyrum, et prunis lapidosa rubescere corna.

But, what is much more curious, the delicate process of budding was as scientifically performed at that period as by the most skilful gardener of the present century. Nothing can be more precise than the following elegant description of Roman budding: —

> Nec modus inserere, atque oculos imponere simplex.
> Nam qua se medio trudunt de cortice gemmæ,
> Et tenues rumpunt tunicas, angustus in ipso
> Fit nodo sinus; huc aliena ex arbore germen
> Includunt, udoque docent inolescere libro.

Again of crown grafting: —

> Aut rursum enodes trunci resecantur, et alte
> Finditur in solidum cuneis via: deinde feraces
> Plantæ immittuntur: nec longum tempus et ingens
> Exiit ad cœlum ramis felicibus arbos,
> Miraturque novas frondes et non sua poma.

A cessation of all philosophical inquiry into the nature of vegetation endured about 1700 years, during the whole of which time scarcely a single addition was made to the stock of knowledge left behind him by Theophrastus. But with the revival of letters a new direction was given to researches in natural history. Men ceased to content themselves with blindly copying the writers of antiquity, and set themselves in earnest to examine the objects of nature that surrounded them. The woods, the plains, the rivers, the ocean, the valleys, and the mountains, were investigated with an ardour that soon made amends for ancient indifference. The first consequence of this was a discovery of the worthlessness of the greater part of those writers to whom the world had so long been bound in servile obedience. The spirit of inquiry once excited, men speedily learned to estimate rightly the greater value of facts than of assertions; one discovery produced another, and in a few years a new foundation was laid of that imperfect but beautiful science which constitutes modern botany. In the early part of the sixteenth century, John Manardi, a native of Ferrara, described the real nature of the anther. He was followed by a long train of writers of various merit, who at first indeed applied themselves exclusively to the collection of new species, but subsequently to an examination of the physiological characters of plants, and to the laws applied by nature to the government of the vegetable kingdom.

Up to the middle of the seventeenth century, vegetable physiology had been grounded upon observations entirely independent of anatomical investigation. But about this time the accurate inquiries of two naturalists, one an Englishman and the other an Italian, gave a new feature to the study; and what was vague or imaginary in the opinions entertained upon the vital functions of vegetables gave way to conclusions precise, and supported upon the firm basis of careful observation. The nature of cellular tissue, of spiral vessels, of ducts, of woody tissue; the composition of the internal parts of plants, and the functions of the whole — excited inquiry, and received reasonable if not accurate explanations. Collections of facts and of ideas accumulated on all hands, and the confusion that had once been caused by ignorance threatened again to overwhelm the science, in consequence of the rapid addition of new matter which

there was no means of keeping in order. Hence *systematists* sprung up; a race of inquirers to whose labours the present advanced state of botany is no doubt much to be ascribed. That the efforts of the earliest of these writers should have proved unsuccessful, will excite no surprise: with little knowledge of vegetable physiology or anatomy, for it must not be forgotten that for a long time, and even now, vegetable physiology and systematic botany were considered as distinct sciences, and with scarcely any notion of the laws of affinity and metamorphosis, they could not be expected to succeed. We should rather wonder at what they did, than at what they omitted to do. Many of them had great merit, especially John Ray, an English deprived clergyman, and Joseph Pitton de Tournefort, a professor of botany at Paris, who flourished in the end of the seventeenth century, and upon whose systems the modern arrangement according to natural orders is essentially founded. This, however, and all others, was for a time eclipsed by another, better adapted to the circumstances of the times, and emanating from a writer who, having the courage and talent to carry reformation into every branch of natural history, imparted a lustre to his peculiar system of classification which has only now, after the lapse of a century, fallen into disuse among men of science.

Charles Linné, or Linnæus, as he is usually called, was a person exactly adapted to the science of the time in which he lived. The various departments of natural history had not at that time any thing like their present extensive range, and might without difficulty be investigated by a single naturalist. They were all equally in need of revision and improvement; they all wanted a settled code of laws to reconcile the fluctuating and jarring opinions which at that time prevailed, and above all things the nomenclature of natural history required to be reduced to one uniform standard. For this Linnæus was peculiarly well adapted. Nature had gifted him with a logical accuracy of reasoning, and a neatness and perspicuity of expression, which carried with them a charm that the world was not slow to appreciate; and these produced the stronger impression, because naturalists had previously been but little accustomed to them. The opinions of Linnæus were received as if oracular, and their faults were lost in the splendour which they threw over the whole of the organic world. But unfortunately Linnæus knew nothing of vegetable physiology. His opinions upon this subject are among the most worthless which are recorded in the history of science; and consequently his writings lost much of the permanent value which the originality of his ideas and the acuteness of his perception would have otherwise insured them. But notwithstanding this defect, he not only established his famous method of arrangement, which for a long time susperseded all others, but laid the foundation, although upon imaginary principles, of the curious laws of morphology, upon which modern botany founds one of its greatest claims to perfection. The notion that all the parts of plants are mere modifications of leaves, faintly shadowed forth by Linnæus in his *Species Plantarum*, became the subject of a special and most original dissertation by the German poet Göthe, in 1790. This doctrine was believed by the botanists of that day to be worthy only of the poetical fame of its illustrious author; but he lived to see his opinions received, almost without change, by every botanist of reputation.

After the artificial system of Linnæus followed the natural system of Jussieu. Vegetable anatomy became an important branch of inquiry in the hands of Kieser; the researches of Knight and others gave a new character to vegetable physiology; and the early part of the present century has seen the science by these and other means assume an entirely new appearance. Our knowledge of the vital functions of plants reposes upon the sure basis of exact observation and careful experiments; the theory of the plan upon which the organs of vegetation and fructification are severally combined into so many numerous forms is settled upon the clearest evidence; and classifications, to a great degree freed from the trammels of prejudice or narrow views, have assumed that position in science to which their importance, when rightly studied, entitles them.

The only two botanical arrangements now in use are the Linnæan and the Natural. The former is an attempt at classifying plants according to their agreement in some single characters, without reference to their resemblances or differences in any other respect, just as words are arranged in a dictionary by the accordance of their initial letters; the other is a scheme for placing next each other all those plants which have the greatest resemblance, and at the greatest distance those which are most dissimilar. To effect this, every kind of structure that plants possess is made use of; distinctions derived from great physiological peculiarities are considered fundamental, and form classes; subordinate to them are characters derived from diversities of external structure, and they are valued according to their permanence or frequency, &c. The final result being the making up of the vegetable kingdom into associations, called natural orders, which are supposed to consist of genera more closely allied to each other than to any thing else. For an explanation of the details of these two kinds of classification the reader is referred to the separate works that have been published on the subject; space can be given in this place only to a very general account of them.

The sexual system of Linnæus depends upon the number and relative position or degree of combination of the stamens and styles. It has been so often explained, and is so rapidly falling into disuse, that we shall content ourselves with the shortest possible description of the classes and orders.

Class I.	Stamen 1	Monandria.
II.	Stamens 2	Diandria.
III.	Stamens 3	Triandria.
IV.	Stamens 4	Tetrandria.
V.	Stamens 5	Pentandria.
VI.	Stamens 6	Hexandria.
VII.	Stamens 7	Heptandria.
VIII.	Stamens 8	Octandria.
IX.	Stamens 9	Enneandria.
X.	Stamens 10	Decandria.
XI.	Stamens 12—19	Dodecandria.
XII.	Stamens 20 or more, inserted into the calyx	Icosandria.
XIII.	Stamens 20 or more, inserted into the receptacle	Polyandria.
XIV.	Stamens 2 long and 2 short	Didynamia.
XV.	Stamens 4 long and 2 short	Tetradynamia
XVI.	Stamens united by their filaments into a tube	Monadelphia.
XVII.	Stamens united by their filaments into two parcels	Diadelphia.
XVIII.	Stamens united by their filaments into several parcels	Polyadelphia.
XIX.	Stamens united by their anthers into a tube	Syngenesia.
XX.	Stamens united with the pistil	Gynandria.
XXI.	Stamens and pistils in separate flowers, but both growing on the same plant	Monœcia.
XXII.	Stamens and pistils not only in separate flowers, but those flowers situated upon two different plants	Diœcia.
XXIII.	Stamens and pistils separate in some flowers, united in others, either on the same plant, or two or three different ones	Polygamia.
XXIV.	Stamens and pistils either not ascertained, or not to be discovered with any certainty, insomuch that the plants cannot be referred to any of the foregoing classes	Cryptogamia.

The characters of the orders depend upon the number of the styles, or of the stigmas, if there be no style, in the first thirteen classes; such are accordingly named,—

Monogynia	style 1
Digynia	2
Trigynia	3
Tetragynia	4
Pentagynia	5
Hexagynia	6
Heptagynia	7
Octogynia	8
Enneagynia	9
Decagynia	10
Dodecagynia	12
Polygynia	more than 12.

In the 14th class, Didynamia, the orders depend upon the nature of the ovary. In *Gymnospermia*, the first order, the ovary is divided into four lobes, from the base of which proceeds a single style, and within each of which is contained a single seed. In *Angiospermia*, the 2nd order, the ovary is not lobed, and is usually two-celled, and many-seeded.

In the 15th class, Tetradynamia, the orders are characterized by the form of the fruit: *Siliquosæ* have a long pod; *Siliculosæ* have a short one.

The orders of the 16th, 17th, and 18th classes, Monadelphia, Diadelphia, and Polyadelphia, depend upon the number of the stamens, and have the same nomenclature as the thirteen first classes.

The orders of Syngenesia are determined by the ar-

rangement of their flowers, and by the sex of their florets: thus—

Polygamia has flowers crowded together in heads.

1. *Polygamia æqualis* has each floret hermaphrodite, or furnished with perfect stamens and pistil.
2. *Polygamia superflua* has the florets of the disk hermaphrodite; those of the ray female only.
3. *Polygamia frustranea* has the florets of the disk hermaphrodite; those of the ray sterile.
4. *Polygamia necessaria* has the florets of the disk male, of the ray female.
5. *Polygamia segregata* "has several florets, either simple or compound, but with a proper calyx, included within one common calyx."

Monogamia has the flowers separate, not crowded in heads. This order is generally abolished by Linnæan botanists, but for no good reason.

The orders of the 20th, 21st, and 22nd classes are distinguished by the number, &c. of the stamens.

The two orders of the 23rd class depend upon whether the genera are monœcious or diœcious.

The last class, *Cryptogamia*, is divided into orders according to the principles of the natural system, namely, 1. Filices; 2. Musci; 3. Hepaticæ; 4. Algæ; 5. Fungi.

With regard to the natural system of botany, that formed by Jussieu out of the views of Ray, Tournefort, and others, in combination with very numerous observations of his own, is the basis of what is at present understood by that name. It has, however, been much modified by succeeding systematists, and will undoubtedly undergo many more changes in its details. The view taken of the subject by De Candolle, the learned professor at Geneva, is thus stated by himself:—"I have established in my *Theorie Elémentaire*, that the proof of a classification of plants being natural is furnished when similar results are arrived at, whether from considerations drawn from the *reproductive* organs or from those of *vegetation.* Considered with reference to the organs of reproduction (or fructification), the vegetable kingdom has been divided by Linnæus into two grand series, the *Phanerogamous* and the *Cryptogamous.* These series are not merely distinguished because in the first the sexual organs are visible to the naked eye, and in the latter are microscopical. Such a difference, which might depend only upon the absolute size of the organs, could be in itself of little moment; but it is connected with a real difference of structure. Phanerogamous plants have their organs of fructification arranged upon a more or less symmetrical plan, and surrounded by integuments themselves also arranged symmetrically. Cryptogamous plants have the sexual organs disposed without order, and surrounded by integuments scarcely perceptible, and still more disorderly; or they have no sexual organs that have been proved to be so."

Phanerogamous plants have long been divided into *Dicotyledons*, or plants whose embryos present cotyledons opposite or verticillate upon the same plane, and whose minimum is consequently 2; and into *Monocotyledons*, whose cotyledons or earliest leaves are alternate, so that the minimum is 1, or that the first, when there are two, is more particularly intended to nourish the young plant.

Cryptogamous plants should in like manner be divided into two classes, the Ætheogamous and the Amphigamous. For the first I take the name of *Ætheogamous*, invented by Beauvois, but limiting its application. This term, which signifies plants with unusual fructification, suits well enough the class here indicated, and which is characterized by having sexual organs distinct and visible under the microscope, but formed upon a plan totally different from that of Phanerogamous plants; such are Equisetaceæ, Ferns, Lycopodiaceæ, Mosses, and Hepaticæ. I give the second class the name of *Amphigamæ*, to indicate the doubtful nature of their fructification; some authors have called them Agamæ, but that is, I think, to assert more than is quite certain. The character of Amphigamæ is to present to view no sexual organ, even under the microscope; but we cannot affirm that the spores that they produce have not received a sort of impregnation in the very cells which generated them. It is for the sake of expressing this doubt that I employ the word Amphigamæ. Thus with respect to their organs of reproduction, plants are clearly divided into four great classes. Let us next examine them with reference to their organs of vegetation. The first division that may be established is deduced from the absence or presence of vessels; and in this view I separate plants into two series—the *vascular*, which have vessels and stomates manifest during their whole life; and *cellular*, or those which consist of nothing but cellules either throughout their life or in their first foliaceous organs. Vascular plants are divided into *Exogens*, of which the wood increases by the addition of new layers placed on the outside of the older; and *Endogens*, whose trunk increases by the addition of new fibres to the centre of the cylinder already formed. Cellular plants, in like manner, are subdivided into *semi-vascular* and *cellular*. Under the first of these names I comprehend the orders which grow with leafy cotyledons, but composed of cellular tissue only, and destitute of stomates. Eventually they assume organs in which vessels and stomates exist: this development, which gives them some resemblance to Endogens, takes place rapidly in Equisetaceæ, Ferns, and Lycopodiaceæ; and the observations of anatomists have shown that the same thing occurs, but later and less perfectly, in Mosses and Hepaticæ; so that it is a matter of some doubt whether they ought to be referred to the semi-vascular or succeeding class. *Cellular* plants have long been known to be destitute of both vessels and stomates, and to present only a homogeneous mass, where the distinction of stem, leaves, and roots can only be established analogically.

Looking back at this explanation, it is obvious that the vegetable kingdom may be represented by the following table.

Divisions formed by the Organs of Fructification.		*Divisions formed by the Organs of Nutrition.*
I. PHANEROGAMOUS,	*or*	VASCULAR.
Class 1. Dicotyledons,	*or*	Exogens.
2. Monocotyledons,	*or*	Endogens.
II. CRYPTOGAMOUS,	*or*	CELLULAR.
3. Ætheogamous,	*or*	Semivascular.
4. Amphigamous,	*or*	Cellular.

Or, if it is preferred, in this other form, which is almost equally regular:—

I. SEXUAL, being furnished with sexual organs,	*or*	Having vessels and stomates at some period of their existence.
Class 1. Dicotyledons,	*or*	Exogens.
2. Monocotyledons,	*or*	Endogens.
3. Ætheogamous,	*or*	Semivascular.
II. Without distinct sexes,	*or*	Without either vessels or stomates at any age.
4. Amphigamous,	*or*	Cellular.

But notwithstanding the apparent clearness of this system, and the importance of the arguments upon which it is founded, it is far from being unobjectionable. In the first place, the distinction drawn between the two classes of Cryptogamic plants is unfounded, both as regards the presence or absence of both vessels and sexes. Ferns and Lycopodiacæ, in which the vascular system is most developed, have no more trace of sexes than Fungi; and on the other hand, in Mosses and Hepaticæ, in which there is the most distinct formation of something analogous to sexes, there is no trace whatever of a vascular system. The difference, then, between Amphigamæ and Ætheogamæ falls to the ground. and in fact is analogically bad; for there are vascular and cellular orders in both the great classes of Exogens and Endogens, which ought therefore themselves to be subdivided into vascular and cellular, in order to form a consistent system; and this difference appears to be connected with a very general tendency, visible in the vegetable kingdom, to produce an impoverished or degraded condition of all great types of structure. Thus, among Exogens, Onagracæ are merely cellular in Hippuris and Myriophyllum, Urticaceæ in Ceratophylleæ, and the orders Callitrichaceæ and Podostemaceæ are other instances of the same fact; and, in Endogens, Naiadaceæ and Pistiaceæ, or at least Lemna, are as completely cellular as Algaceæ.

In the next place, circumstances of greater importance are omitted by M. De Candolle from his statement than some of those included in it. If Cryptogamic are to be separated from Phanerogamous plants by their vegetation, it is rather by their manner of growth than by any peculiarity in their vascular system. Phanerogamous plants might be called *Pleurogens*, from their growing by the sides as well as at the ends, thus increasing symmetrically both in length, density, and thickness. Cryptogamous plants grow either by simple elongation, without increasing materially in density; or they expand irregularly in all directions, and hence have been termed *Acrogens.* No circumstance can well be more important than the manner in which impregnation takes place. In common Exogens there is an ovarian covering, through the tapering apex of which, called style, impregnation takes effect by aid of a part called the stigma; but in other Exogens impregnation is effected by direct contact between the egg or ovule and the pollen; and a simple mode of veining in the leaves, together with a very small development of the vascular system, accompany this. Hence such plants, called *Gymnosperms*, ought to be regarded as a class of as much importance as Exogens themselves. Again, among plants in some respects participating in the organization of Endogens are species called *Rhizanths*, having a fungoid vegetation, a nearly total absence of the vascular system, and a most remarkable method of propagation. With the ordinary sexes of Endogens they are said to combine the spores of Cryptogamic plants, and thus

hold a sort of middle station between the two great series of plants recognised by Linnæus. Such a kind of vegetation is far too important to be omitted from consideration in determining the classes, as the fundamental divisions of the vegetable kingdom are termed.

For these reasons the writer of the present notice has proposed a material modification of De Candolle's statement, which may be expressed as follows.

PLANTS,

According to their Fructification.		*According to their Vegetation.*
I. Having flowers and sexes (Phanerogamous),	*or*	I. Their axis increasing symmetrically in density and breadth as well as length (Pleurogens).
a. Minimum of cotyledons 2,	*or*	*a.* Stem in concentric layers (Exogens).
Class 1. *Dicotyledons*,	*or*	*Veins of leaves netted.*
Class 2. *Gymnosperms*,	*or*	*Veins of leaves netted or forked.*
b. Minimum of cotyledons 1,	*or*	*b.* Stem a confused mass of wood and cellular tissue.
Class 3. *Monocotyledons*,	*or*	*Veins of leaves parallel, and not netted.*
c. Acotyledons,	*or*	*c.* Vegetation fungoid.
Class 4. *Rhizanths.*		Class 4. *Rhizanths.*
II. Having neither flowers nor sexes,	*or*	II. Their axis increasing by simple elongation or irregular expansion.
Class 5. *Cryptogamic plants*,	*or*	Class 5. *Acrogens.*

For the details of this system the reader is referred to the *Natural System of Botany*, 2nd ed.

BOTA'NIC GARDEN. A garden devoted to the culture of a collection of plants, with reference to the science of botany. The legitimate object of gardens of this description appears to be to collect and cultivate, at the public expence, all the species and varieties of plants that can be cultivated in the given climate, with or without the aid of glass; and then to distribute these to private individuals throughout the district by which the botanic garden is supported. The most complete system of this kind ever established appears to have been that of France soon after the revolution. All the botanical articles that could be procured from other countries were sent to the botanic garden at Paris; and after they had borne seeds or been propagated there, the progeny was distributed among the provincial botanic gardens, of which there is one or more in every department. After being propagated in the provincial botanic gardens, the seeds or progeny were given out, free of expence, to whoever in the district to which the garden belonged thought fit to apply for them. As the useful species and varieties were as much attended to in these gardens as those which were cultivated only in a scientific point of view, the greatest facilities were thus given to the spread of every useful grain, pulse, culinary vegetable, and fruit, over the whole of France. Something of the same kind may be considered as taking place in Great Britain; but it is more the effect of accident than the result of design, as the giving out of plants is not considered in Britain as an essential part of the system of management of a royal or government botanic garden.

BO'TANY BAY RESIN. A yellow aromatic resin which exudes from the trunk of the *Acarois resinifera* of New Holland.

BOTRYLLA'RIANS, BOTRYLARIÆ. (Gr. βοτρυς, *a bunch of grapes.*) In Zoology, a family of singular compound Tunicaries or Ascidians, in which several distinct individuals are arranged in a circle round a central aperture common to the rectum of each, while the mouths are distinct and placed at the circumference.

BOTRYO'IDAL. (Gr. βοτρυς, *a bunch of grapes; ειδος, like.*) When a part is clustered like a bunch of grapes.

BO'TRYOLITE. (Gr. βοτρυς, *a cluster of grapes; λιθος, stone.*) Botryoidal siliceous borate of lime.

BO'TTOM HEAT. A term applied in Horticulture to the temperature communicated to certain soils by fermenting and decomposing substances placed underneath them: leaves, fresh dung, and the refuse bark of the tan-yard, are often used for this purpose; and the system is applied to pine-apples, melons, cucumbers, and other plants grown in pits or frames.

BOTTOM RAIL. (Sax. botm.) In Architecture, a term used for denoting the lowest horizontal rail of a framed door.

BO'TTOMRY. In Commercial Law, is in effect a mortgage of a ship, being an agreement entered into by an owner or his agent, whereby, in consideration of a sum of money advanced for the use of the ship, the borrower undertakes to repay the same, with interest, if the ship terminate her voyage successfully; and binds or hypothecates the ship for the performance of the contract. The instrument by which this contract is effected is sometimes in the shape of a deed poll, and sometimes in that of a bond. On bottomry contracts the lender runs the risk of the voyage, and in consideration of the risk the interest he may take is unlimited. The master has authority to hypothecate a ship or its freight (*see* RESPONDENTIA) at a foreign port, in case of necessity, for the purposes of the voyage. In such case, if the loan be not repaid within the time prescribed, the agent of the lenders applies to the Court of Admiralty, with certain affidavits, and procures authority to arrest the ship, which may be sold, if necessary, under the authority of the court. Where several loans of this description have been made on the same voyage, the last lender is entitled to priority of payment out of the proceeds of the sale.

BOU'DOIR. (Fr. bouder, *to pout.*) In Architecture, a small room or cabinet, usually near the bed-chamber and dressing room, for the private retirement of the master or mistress of the house.

BOU'GET, WATER-BUDGET, or DOSSER. In Heraldry, a bearing supposed to represent a vessel for carrying water

BOU'LTIN. (Fr.) In Architecture, a name given to a moulding whose section is nearly a quadrant of a circle, whose diameter being horizontal, the contour is convex in respect of a vertical to such diameter. It is more usually called the egg or quarter round.

BOU'NTY. In Commerce and the Arts, a premium paid by government to the producers, exporters, or importers of certain articles, or to those who employ ships in certain trades, when the profits resulting from these respective branches of industry are alleged to be insufficient. Bounties on *production* are usually given in the view of encouraging the establishment of some new branch of industry, or of fostering and extending a branch that is believed to be of paramount importance. Bounties on *exportation* and *importation* are granted to the exporters of certain British commodities on their taking oath, or in some cases giving bond, not to reland the same in England. Public opinion was formerly very divided as to the advantage of granting bounties; but at present the impolicy of such a practice appears to be almost universally admitted. For it will be found that in all old settled and wealthy countries, numbers of individuals are always ready to embark in every new undertaking, if it promise to be really advantageous, without any stimulus from government; and if a branch of industry already established be really important and suitable for the country, it will assuredly be prosecuted to the necessary extent without any encouragement beyond the natural demand for its produce. For further details upon this subject, see the article TARIFF.

BOU'NTY, QUEEN ANNE'S. The produce of the first fruits and tenths due to the crown (*see* art. FIRST FRUITS), which were made over by Queen Anne to a corporation established in the year 1704 for the purpose of augmenting poor livings under 50*l.* a year.

BOUSTROPHE'DON. (Gr. βοῦς, *an ox; στρεφω, I turn.*) A word descriptive of a mode of writing common among the early Greeks until nearly the middle of the fifth century before Christ; viz. in alternate lines from right to left and from left to right, as fields are ploughed in furrows having an alternate direction, from whence the derivation. *See* ALPHABET.

BOUT. In Agriculture, is one turn or course of a plough in ploughing a ridge.

BO'VEY COAL. A species of bituminous wood found at Bovey Hayfield, near Exeter.

BOW. An ancient weapon of offence, made of wood, horn, steel, or some other elastic substance, by which arrows are thrown. The force with which the arrow is propelled is proportioned to that with which the bow is bent, and to the quickness with which it recovers its former position.

BOW or BAY WINDOW. (Sax. boga, *a bow.*) In Architecture, a window projecting from the general face of a building, of a curved or polygonal form on the plan.

BO'WLDERS. Rounded masses of stone lying upon the surface, or loosely imbedded in the soil.

BO'WLINE. A rope from near the middle of the weather edge or leech of a sail, leading forward. Its use is to keep the leech forward, that the wind may get at the after side of the sail when very oblique to its direction.

BOWS. The two sides of the fore extremity of a vessel, as the starboard and larboard bows.

BO'WSPRIT. In Naval Architecture, is a kind of mast which rests slopewise on the head of the main stern, having its lower end fastened to the partners of the fore mast. It carries the sprit-sail, sprit top-sail, and jack-staff. It is exposed to violent action, especially from being struck by heavy seas, into which the ship, in plunging, dips it; and though very firmly secured by the bob-stays and side ropes called *shrouds*, is very often *carried away* or *sprung*.

BOX. (Πυξος, the Greek name of the plant.) The hard

compact wood of *Buxus sempervirens*, so much used by wood engravers, and for the turner's purposes. This evergreen bush or small tree is found all over Europe, even upon the chalk hills of England; but it acquires its largest dimensions in the south. It is from Turkey that the principal part of the wood is imported into England, under a duty of 5*l*. a ton: whether or not all this is really furnished by *Buxus sempervirens* is not known. It is not improbable that *Buxus balearica*, a larger species, too tender to thrive in this country, may furnish a part at least of that which comes from the Mediterranean. It is said that the wood of this species is coarser and of a brighter yellow than that of the common species. The box plant is best known for its use in gardens as edging to borders; the kind so employed is a dwarf variety of *Buxus sempervirens*.

BOX DRAIN. An underground drain, regularly built with upright sides and a flat stone or brick cover, so that the close section has the appearance of a square box.

BOX HAULING. In Navigation, is bringing a ship when close-hauled round upon the other tack, when she refuses to tack and there is not room to wear. By throwing the head sails aback she gets sternway; the helm thereupon being put a-lee, the ship's head falls rapidly off from the wind, which she soon brings aft; she is then speedily rounded-to with but little loss of ground.

BO'XING OFF. Throwing the head sails aback to force the ship's head rapidly off the wind.

BO'XING THE COMPASS. Repeating the points in order.

BO'XINGS. *See* LINING.

BRA'CCATE. (Bracca, *breeches*.) In Ornithology, when the feet are concealed by long feathers descending from the tibiæ.

BRACE. In Sea language, a rope fastened to the extremity of the yard, for the purpose of traversing the sails when it is necessary to change their position.

BRACE. (Fr. embrasser, *to embrace*.) In Architecture, an inclined piece of timber used in trussed partitions and in framed roofs, in order to form a triangle by which the assemblage of pieces composing the framing is stiffened. If a brace is used to support a rafter, it is called a strut. When braces are used in roofs and partitions they should be disposed in pairs, and introduced in opposite directions.

BRACE. (Fr. embrasser, *to embrace*.) In Music, the line or bracket at the beginning of each set of staves which ties them together in a vertical direction.

BRACHALY'TRA. (Gr. βραχυς, *short*; ελυτρον, *sheath*.) The name of an extensive group of Coleopterous insects, including all such as have the elytra so short as not to exceed one third the length of the abdomen. To this section belongs the well-known species called the devil's coach-horse (*Staphylinus oleus*).

BRA'CHIAL. (Lat. brachium, *the arm*.) Belonging to the arm; as brachial nerves, vessels, &c.

BRACHI'NUS. A genus of Coleopterous insects, now the type of a family (*Brachinidæ*), including those singular beetles which from their defensive anal explosions are termed "bombardiers." Of these there are five British species, the best known of which is the *Brachinus crepitans* of Linnæus.

BRA'CHIOMIS. The name given by Müller to a genus of Rotiferous Infusorial Animalcules, now subdivided into many distinct genera.

BRA'CHIOPODS, BRACHIOPODA. (Gr. βραχιων, *an arm*; πους, *a foot*.) An order of Acephalous or headless bivalve Mollusks, characterized by having the mantle organized so as to be serviceable for respiration, and by having two long fleshy, ciliated, spiral arms, or labiate processes; whence Cuvier conceived the name, which in his system designates a distinct class of Acephala. *See* PALLIOBRANCHIATES.

BRA'CHIUM. (Lat.) In Mammalogy, is restricted to the second segment of the anterior extremity, which is articulated proximally with the scapula, and distally with the antibrachium. In Entomology, signifies the first pair of legs of Hexapods, the direction of which is usually towards the head.

BRA'CHYCATALECTIC. (Gr. βραχυς, *short*, and καταληκτικος, *deficient*.) A verse wanting two syllables to complete its length (in Greek and Latin poetry).

BRACHY'GRAPHY. (Gr. βράχυς, *short*, and γράφω, *I write*.) The art of writing by abbreviations. (*See* TACHYGRAPHY.) The notæ Tironianæ, among the Romans, were a species of short-hand invented by one Tiro, a freedman of Cicero.

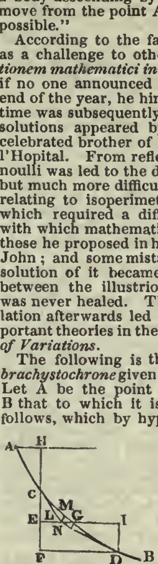
BRACHY'PTEROUS. (Gr. βραχυς, *short*; πτερον, *a wing*.) In Ornithology, when the folded wings of a bird do not reach to the base of the tail.

BRACHY'STOCHRONE. (Gr. βραχυς, *short*, and χρονος, *time*.) The name given by John Bernoulli to the curve which possesses this property, that a body setting out from a given point A, and impelled merely by the force of gravity, will arrive at another point B in a shorter time by moving in this curve, than if it followed any other direction. The problem of the *brachystochrone* is famous in the history of the new geometry. It was first proposed by John Bernoulli in the Leipsic *Acta Eruditorum* for June 1696, in the following terms: —

"Two points, A and B, being given in the same vertical plane; it is required to assign the path through which a body descending by its own gravity, and beginning to move from the point A, will arrive at B in the least time possible."

According to the fashion of that age, it was proposed as a challenge to other mathematicians, *ad cujus solutionem mathematici invitantur;* with the declaration that if no one announced the nature of the curve before the end of the year, he himself would make it known. The time was subsequently extended to a year, within which solutions appeared by Newton, James Bernoulli (the celebrated brother of the proposer), and the Marquis de l'Hopital. From reflecting on this problem, James Bernoulli was led to the discovery and solution of a kindred but much more difficult class of questions; namely, those relating to isoperimetrical figures, the investigation of which required a different kind of analysis from that with which mathematicians were yet acquainted. One of these he proposed in his turn as a challenge to his brother John; and some mistakes into which the latter fell in the solution of it became the occasion of an angry quarrel between the illustrious brothers, which unfortunately was never healed. The prosecution of a similar speculation afterwards led Lagrange to one of the most important theories in the higher mathematics — the *Calculus of Variations*.

The following is the solution of the problem of the *brachystochrone* given by James Bernoulli. (*Opera*, p.768.) Let A be the point from which the body is to move, B that to which it is to go, and A C D B the path it follows, which by hypothesis is wholly situated in the same plane. It is not necessary, however, that the plane be vertical. Take any small portion of the curve C D; then it is obvious that if A B be the path through which the body will descend from A to B in the least time possible, it must also pass from C to D in a shorter time than if it followed any other direction. For suppose



it to pass from C to D by another path, C L N D, in shorter time than by C M G D; then it must also pass from A to B in shorter time through A C L N D than through A C M G D, which is contrary to the hypothesis. This being premised, let A H be drawn horizontally through A, C H perpendicular and D F parallel to A H through the points C and D; also let C F be divided into two equal parts in E, and complete the parallelogram E F D I; the object is to find the point G in the straight line E I, or (which comes to the same thing) the inclination of the two elements of the curve C G and G D to each other, so that the time of descent through C G + time of descent through G D (which may be thus denoted, t C G + t G D) may be a minimum. For this purpose assume another point L in E I, so that G L may be regarded as infinitely small in comparison of E G; and having drawn C L and D L, let L M and G N be respectively perpendicular to C G and D L. Now, variable quantities when they are infinitely near their maxima or minima, may be regarded as constant; therefore t C L + t L D = t C G + t G D, and consequently t C G − t C L = t L D − t G D. By the theory of the descent of heavy bodies,

$$CE : CG = tCE : tCG,$$

and $CE : CL = tCE : tCL$;

therefore,

$$CE : CG - CL \text{ (or } MG) = tCE : tCG - tCL.$$

But by similar triangles,

$$MG : GL = EG : CG;$$

therefore, combining the two last proportions,

$$(1)\quad CE : GL = EG \times tCE : CG \times (tCG - tCL).$$

In like manner,

$$EF : GD = tEF : tGD$$

$$EF : LD = tEF : tLD;$$

therefore,

$$EF : LD - GD \text{ (or } LN) = tEF : tLD - tGD.$$

But $LN : GL = GI : GD$;

therefore,

$$(2)\quad EF \text{ (or } CE) : GL = GI \times tEF : GD \times (tLD - tGD).$$

From the two analogies (1) and (2), we have now $EG \times tCE : CG \times (tCG - tCL) = GI \times tEF : GD \times (tLD - tGD)$; or, $EG \times tCE : GI \times tEF = CG \times (tCG - tCL) : GD \times (tLD - tGD)$. But it was proved that $tCG - tCL = tLD - tGD$; and by the laws of falling bodies, t C E is reciprocally proportional to $\sqrt{HC}$, and t E F reciprocally as $\sqrt{HE}$; therefore by substitution,

$$\frac{EG}{\sqrt{HC}} : \frac{GI}{\sqrt{HE}} = CG : GD,$$

a known property of the common cycloid; which, there-

fore, is the brachystochrone, or curve of quickest descent. In the modern analysis the investigation of the brachystochrone is usually proposed as an example of the method of *Variations.*

BRA'CHYURES, BRA'CHYU'RA. (Gr. βραχυς, *short*, and ουρα, *a tail.*) A tribe of Decapodous Crustacea, in which the tail or post-abdomen is short, and folded beneath the trunk; commonly called "crabs."

BRA'CKET. (From brachietto, Ital.) In Architecture, a projecting piece for carrying a superincumbent weight. In large cornices executed in plaster the series of projecting pieces to which the laths are nailed is called bracketing.

BRA'CON. A Fabrician genus of Hymenopterous insects of the parasitic tribe of Pupivorous Ichneumons: it is now the type of a family (*Braconidæ*), distinguished from the true Ichneumons by having the maxillary palps five-jointed, and the labial ones either three or four-jointed, and by wanting the internal discoidal cell of the upper wings. The genera of this family are *Bracon* proper; *Aphidius*, the species of which prey upon the plant-lice; *Stephanus*, *Cœlinius*, *Spathius*, *Perilitus*, *Hybrizon*, *Leiophron*, *Agathis*, *Microdus*, *Hormius*, *Ichnentes*, *Microgaster*, and *Blacus*.

BRACT. An altered leaf, which is placed at the base of a flower on the outside of the calyx. It is the first attempt made by the common leaves to change into the floral organs. In general the bract is small and inconspicuous, but it occasionally acquires a considerable size and a brilliant colour, as in *Salira comosa* and *splendens*, and the Brazilian pine-apple, and more especially in the various kinds of Arum, where it constitutes the large enveloping leaf, called spath, in which the spadix of those extraordinary plants is enveloped. This word forms the adjectives *bractiscent*, assuming the appearance of a bract; *bractial*, furnished with bracts; *bractiolate*, having little bracts. A cupule is a collection of bracts united into a cup; an involucre is the same organs arranged in a whorl. The flowers of grasses and cyperaceous plants consist of nothing but little bracts called *paleæ* and *glumes.*

BRA'DYPODS, BRADY'PODA. (Gr. Βραδυς, *slow*, πους, *foot; slow-footed.*) A family of Macronyhous or Edentate Mammals, including the two-toed and three-toed sloths.

BRA'HMANS. (Βραχμανες among the Greeks, *Bràhman* in the Indian dialects, and *Bramin* among the Europeans.) The first or highest of the four castes of Hindoos, said to have proceeded from the mouth of Brahm (the seat of wisdom). They form the learned or sacerdotal class; and its members have maintained a more extensive sway than the priests of any other nation. Their chief privileges consist in reading the Veda or sacred volume, in instituting sacrifices, in imparting religious instruction, in asking alms, and in exemption from capital punishment. The whole life of the Brahmans is devoted to the study of the sacred writings, and is divided into four periods. The first begins at the age of seven, when the duty of the young novitiate consists in learning to read and write, in studying the Veda, and in familiarising himself with the privileges of his order. In the second stage of a Brahman's life he is allowed to marry, and to engage in commercial speculations. In the third stage, his religious duties become more numerous, and must be rigidly performed. But in the fourth period, the Brahman is admitted to personal communication with the Deity; and this stage is reckoned so pre-eminently holy, that in a single generation it imparts a greater stock of religious importance than is attainable by any other means in a thousand years. (*Menou's Instit.*) The origin of the Brahmans is merged in obscurity. While some ancient writers regard them as a branch of the old Gymnosophists (*Str. Geo.* t. ii. p. 1038.), Diodorus Siculus maintains that they are of much earlier origin. According to the accounts of the best Jewish writers, adopted by Shorestani (an Arabian author of great repute), and sanctioned by the authority of the learned Dr. Hyde (*De Rel. Vet. Persarum*, 31, 32.), the progenitor of the Brahmans was the patriarch Abraham, who in their language is styled Brachman or Brahman. But whatever may have been the origin of the Brahmans, it is certain that the whole learning of India was for ages in their hands. Many of the Grecian sages travelled into India to learn wisdom in that great storehouse of knowledge; and, among others, Pythagoras seems to have borrowed from them the greater part of his mystical philosophy; nay, it is even doubtful whether Aristotle himself did not derive both the materials and the arrangement of his system of logic from the same source. Of ancient Brahminical science the principal remains are their astronomical and trigonometrical methods, both of which have given rise to frequent and learned discussion. Among the modern Brahmans we look in vain for the deep learning that characterized the ancient members of this order; for, with the exception of metaphysical disquisitions, which have always been a favourite study among them, the learning of the present race of Brahmans is exceedingly meagre, being limited almost entirely to the construction of the almanack. Nor is it merely in point of learning that the modern Brahmans have degenerated from their ancestors. Their morals too are wofully deteriorated; and while they are the sole depositaries and ministers of a religion which in point of purity and sublimity of doctrine yields only to the Christian, their conduct is characterized by the most vile and licentious practices; a spirit of avarice, falsehood, and revenge is every where visible; and in many cases superstition and fanaticism have been exchanged for infidelity and atheism. But in spite of these grievous defects, this system maintains its ground; and neither the march of time, the inroads of the conqueror, nor any of the causes that operate in modifying or undermining other institutions, have been able to weaken or subvert the influence of the Brahmans. Whether Great Britain be destined, by the introduction and dissemination of education and Christianity, ultimately to effect what has hitherto baffled every effort, it is not for us to prognosticate; but, assuredly, whatever may be successful in eradicating the Brahminical system, and in substituting in its room a religion whose ministers will practise what they teach, will have achieved the brightest moral triumph in the annals of history. (See *Mills's British India; Asiatic Researches*, passim; *Coleman's Hindoo Mythology; Sir William Jones's History.*)

BRAIN. The chemical examination of the brain of animals was first undertaken by Vauquelin, who found in the human brain 80 water, 7 albumen, 4·53 white fatty matter, 0·70 red fatty matter, 1·12 osmazome, 1·5 phosphorus; acids, salts, and sulphur, 5·15. An elaborate dissertation upon the composition of brain has more lately been published by M. Couerbe (*Annales de Chim. et Phys.* lvi. 160.) He finds a large proportion of *cholesterine* in it; and asserts, as the result of repeated examinations, that the proportion of phosphorus in the brain of persons of sound intellect is from 2 to 2·5 per cent.; in the brain of maniacs it is from 3 to 4·5, and in that of idiots only from 1 to 1·5 per cent.

BRAIN, HUMAN, ANATOMY OF. The brain, or the general mass of nervous matter which occupies the cavity of the skull, constitutes about one thirty-fifth of the weight of the body; it is divided by anatomists into the *cerebrum*, which occupies the whole of the superior part of the cavity of the cranium; the *cerebellum*, which occupies the lower back part; and the *medulla oblongata*, which is the smallest portion, lying at the base of the cranium, beneath the cerebrum and cerebellum, and, passing out of the great foramen of the occipital, becomes as it were the origin of the spinal marrow. The brain is covered by three membranes, two of which are termed *matres*, from the old idea of their giving rise to all the other membranes of the body. The external membrane, more firm than the others, is termed *dura mater:* it is very dense and fibrous, and adheres every where to the inner surface of the cranium, to which it is connected by its vessels; its inner surface is smooth, and it sends off several folds, or *processes*, as they are called, which descend between certain portions of the brain. Of these the principal is the superior longitudinal process, or *falx cerebri*, which descends from the fore to the back part of the skull, between the hemispheres of the brain; from its posterior termination it sends off a layer or expansion, which extends across the back of the skull, and is called the *tentorium*, separating the cerebrum from the cerebellum; from the middle of the tentorium another membranous expansion descends between the lobes of the cerebellum, and terminates at the edge of the great occipital hole, or *foramen magnum*; this is termed the *falx cerebelli*. There are certain spaces or *sinuses* formed in the layers of the dura mater, which perform the office of veins in regard to the blood returning from different parts of the brain, by which any venous pressure upon the substance of the brain is prevented.

When the dura mater is removed, a thin transparent membrane investing the surface and convolutions of the brain is brought to view, which from the delicacy of its texture has been called the *arachnoid* membrane; it is not apparently vascular, and does not pass into the depressions between the convolutions; and it is difficultly separable from the third membrane, or *pia mater*, which is also extremely tender and delicate, but is highly vascular, and from it the blood vessels merge into the substance of the brain, ramifying with great minuteness upon its surface; it lines all the convolutions and cavities of the brain. On removing the upper part of the cranium, and turning aside the dura mater, the brain is seen, divided longitudinally into two ovoid hemispheres, separated, as already stated, by the falx; upon the under side each hemisphere is seen to be divided into three lobes; the two anterior lobes rest upon the orbital plates of the frontal bone; the middle lobes lie upon the fossæ formed by the temporal and sphenoid bones; and the posterior lobes rest upon the tentorium. The superficial convolutions of the brain are divided by clefts of about an inch in depth. On cutting into its substance, the exterior part of the brain appears of a different colour

from the interior, and has been termed the cineritious or cortical substance; it is greyish brown, very soft, and exhibits no appearance of a fibrous texture. Some suppose that it is glandular, and constituted almost entirely of vessels and cellular membrane; it covers the whole of the brain, and is about the tenth of an inch in thickness. The inner substance, termed the white or medullary part of the brain, is of a firmer texture, highly vascular, and when minutely examined appears fibrous, the fibres decussating with each other, and occasionally combining to form commissures.

The *cerebellum*, when viewed from below, is of an elliptical shape, its longest diameter being from side to side, and is divided into two hemispheres separated by the falx cerebelli. In the centre of the upper part of the cerebellum there is a prominence, termed the *vermiform process;* and the whole surface is fissured or sulcated, the pia mater passing between the fissures and conveying vessels to the substance, whilst the arachnoid tunic is merely extended over them.

Such is an outline of the anatomy of the human brain; the details can only be fully understood by reference to illustrative plates upon an adequate scale, which would be incompatible with the plan of this work.

It has been already stated that in man the brain averages in weight 1-35th of the body; it weighs, in fact, about two pounds and a half: in quadrupeds its relative bulk is remarkably smaller; in the dog it averages 1-120th of the weight of the animal; in the horse 1-450th; in the sheep 1-750th; and in the ox 1-800th. This statement has been adduced to show the direct relation between the bulk of the brain and the quantity of mind, the above animals being ranged in the order of their docility and intelligence.

On making a vertical section of either hemisphere of the cerebellum, a central white substance becomes apparent, which ramifies in an arborescent form, and is called *arbor vitæ;* the exterior covering is grey. In front of the cerebellum is a protuberance, termed *pons Varolii* or *tuber annulare;* it is divided by a central groove into two halves, and connected with the cerebrum and cerebellum each by two thick white chords called *cruræ:* the former, or crura cerebri, pass from the tuber forwards and outwards, under the middle part of each hemisphere, in which they are lost; and the latter, the crura cerebelli, are continued backwards and outwards, and terminate in either hemisphere of the cerebellum. The portion of the brain between the tuber annulare and the foramen of the occipital bone is called the *medulla oblongata*, and is continued into the spinal chord; on its anterior surface are four contiguous projections; the two interior ones are called *corpora pyramidalia*, and the two exterior *corpora olivaria.* On carefully removing the membranes which cover the medulla oblongata, and gently opening its middle groove, several white bands are seen passing obliquely from one side to the other, and mutually interwoven, and are termed the *decussating bands.*

The two sides of the brain are mutually connected by commissures or medullary bands, and those of the cerebellum by the pons varolii. The principal connection of the hemispheres of the cerebrum is by a broad medullary band, called the *corpus callosum.* The occasional intervals which separate the parts of the brain are termed *ventricles*, the largest of which are the two *lateral ventricles* in the interior of each hemisphere; their figure is irregular, and they are separated by a tender layer of cerebral matter termed the *septum lucidum;* they are lined by the pia mater. The *middle* or *third ventricle* is a fissure between two convex eminences, situated at the middle and back of the lateral ventricles, and termed *thalami optici.* The *fourth ventricle*, or *ventricle of the cerebellum*, is a cavity between the cerebrum, the tuber annulare, and the medulla oblongata.

BRAIRD. In the agriculture and gardening of Scotland, the term braird is applied to the springing up of seeds, which, when they come up well, are said to have a fine braird.

BRAKE. In Agriculture, a large harrow.

BRA'MA. (Hin.) The name of a divinity in the Hindu Mythology, the fables concerning whom are so numerous, that an accurate development of his character has been hitherto unattainable. As we learn from the Sanscrit lexilogists, the epithets applied to this divinity are very numerous: some of the most usual being "*Swayambhu*, the self-existent, *Parameshti*, who abides in the most exalted places, *Pitamaha*, the great father, *Prajápati*, the lord of creatures, *Lokesa*, the ruler of the world," &c. But the most distinct account of his nature and attributes is to be found in *Coleman's Mythology of the Hindus*, where he is represented as the grandfather of the gods, and equivalent to the Saturn of the Romans. *Brahm*, the highest divinity of the Hindus, to whose name so deep reverence is attached that it is considered criminal to pronounce it, is said to have given birth to Brahma, Vishnu, and Siva, simultaneously; and to have allotted to the first the province of creating, to the second that of preserving, and to the third that of destroying. Accordingly, ever since the creation of the world Brahma has had little or nothing to do, and it will not be till the tenth avatar or incarnation that his services will be put in requisition, when this world is to undergo total annihilation. Meanwhile, however, the other deities, Vishnu and Siva, are constantly engaged in their respective duties of preservation and destruction; and the Hindoos, with that recklessness of the future which is common to them with more civilised communities, lavish all their adoration upon those divinities from whom they expect to derive immediate advantage. Hence, throughout all India, the worship of Brahma is neglected; his altars are overturned, his temples destroyed; in short, nothing has been left but his name, and even that none of the best. Brahma is usually represented with four heads and four hands, either reclining upon a lote tree (the emblem of creation among the Hindoos), or riding upon a swan.

BRAN. The husk of wheat which immediately covers the grain, and which remains in the bolting machine. It is gently laxative; an infusion of it, under the name of *bran tea*, is frequently used as a domestic remedy for coughs and hoarseness. *Calico printers* employ bran and warm water with great success to remove colouring matter from those parts of their goods which are not mordanted.

BRA'NCHIÆ. (Βραγχια, *the gills of a fish.*) The term applied to all vascular organs of an animal body which are destined to submit the circulating fluid in a state of minute subdivision, for the purpose of respiration, to the influence of air contained in water.

BRANCHI'OPODS, BRANCHIO'PODA. (Gr. βραγχια, *gills;* and πους, *a foot.*) An order of Crustaceans, in which the locomotive extremities fulfil the functions of gills.

BRANCHIO'STEGANS, BRANCHIOSTEGI. (Βραγχια, *gills;* στεγω, *I cover.*) A tribe of cartilaginous fishes, comprehending those in which the gills are free, and covered by a membrane; including the sturgeon and chimæra.

BRA'NDY. The spirituous liquor obtained by the distillation of wine. When pure it is perfectly colourless, and only acquires a pale brown or yellow tint from the cask. The deep colour of common brandy, intended to imitate that which it acquires from great age in the cask, is generally given by the addition of burned sugar. The average proportion of alcohol in brandy varies from 48 to 54 *per cent.* The best brandy is made in France, the preference being generally given to that shipped from Cognac. The imports of brandy for home consumption amount to about 1,400,000 gallons a year; but there can be no doubt that the quantity would be much larger, were it not for the oppressive duty of 22*s*. 6*d*. a gallon, with which it is charged.

BRASS. An alloy of copper and zinc. The proportions vary according to the required colour: four parts of copper and one of zinc form an excellent brass. It is usually made by heating copper plates in a mixture of native oxide of zinc, or calamine and charcoal.

BRA'SSAGE. A sum formerly levied to defray the expense of coinage, and taken out of the intrinsic value of the coin. The term is supposed to be derived from *brachiorum labor.*

BRA'SSART. In Plate Armour, the piece which protected the upper arm, between the shoulder-piece and the elbow.

BRASSICA'CEÆ. (Brassica, one of the genera.) One of the names of Cruciferous plants, which see.

BRAZI'L NUT. A South American fruit, commonly sold in the markets of London; it is the seed of a large fruit tree, called *Bertholletia excelsa.*

BRAZIL WOOD. A valuable wood, imported from South America and the West Indies, where it is produced by certain species of *Cæsalpinia*, especially *C. echinata* and *Braziliensis;* large trees with repeatedly pinnated leaves, showy yellow flowers, and long richly coloured stamens. It is used for the preparation of a red dye, but the consumption of it in this country is inconsiderable. It fetches from 60*l*. to 80*l*. a ton in the London market, exclusive of the duty of 2*l*. a ton.

BREACH. In Fortification, a gap or opening made in any part of the walls of the besieged place by the cannon or mines of the besiegers.

BREAD. (Germ. brod.) This important article of food is made of the flour of different grains; but it is only those which contain gluten that admit of conversion into a light or porous and spongy bread, of which *wheaten bread* furnishes the best example. When flour is made into a tough paste or *dough* by the addition of a little water, rolled out into thin cakes, and more or less baked, it forms *biscuit.* For the formation of *bread* a certain degree of fermentation, not unlike vinous fermentation, is requisite, care being taken to avoid acetous fermentation, which renders the bread sour, and to most persons disagreeable. If dough be left to itself in a moderately warm place (between 80° and 120°), a degree of fermentation comes on, which, however, is sluggish, or,

if rapid, *acetous;* so that to effect that kind of fermentation requisite for the production of the best bread, a *ferment* is added, which is either *leaven* or dough which is already in a fermenting state, and which tends to accelerate the process in the mass to which it is added; or *yeast*, the peculiar matter which collects in the form of scum upon beer in the act of fermentation. Of these ferments leaven is slow and uncertain in its effect, and gives a sour and often slightly putrid flavour. Yeast is more effective; and when clean and good, it rapidly induces *panary fermentation;* but it is often bitter, and sometimes has a peculiarly disagreeable smell and taste.

All, then, that is essential to make a loaf of bread is dough to which a certain quantity of yeast has been added. This mixture is put into any convenient mould or form, or merely shaped into one mass; and after having been kept for a short time in rather a warm place, so that fermentation may have begun, it is subjected to the process of baking in a proper oven. Carbonic acid is generated; and the viscidity or texture of the dough preventing the immediate escape of that gas, the whole mass is puffed up by it, and a light porous bread is the result. Along with the carbonic acid traces of alcohol are at the same time produced, but so insignificant and impure as not to be worth notice; hence the attempts which have been made to collect it upon the large scale have entirely failed in an economical point of view. Other flour besides that of wheat will, under similar circumstances, undergo panary fermentation; but the result is a heavy, unpalatable, and often indigestible bread; so that the addition of a certain quantity of wheat flour is almost always had recourse to. It is the *gluten* in wheat which thus peculiarly fits it for the manufacture of bread, chiefly in consequence of the tough and elastic viscidity which it confers upon the dough.

It is well known that *home-made bread* and *baker's bread* are two very different things: the former is usually sweeter, lighter, and more retentive of moisture: the latter, if eaten soon after it has cooled, is pleasant and spongy; but if kept for more than two or three days, it becomes harsh and unpalatable. The cause of this difference may perhaps be obvious from the following details of the operations of the wholesale baker.

In making his dough he takes the water, or part of it, which he intends to use, and having slightly warmed it, dissolves in it a certain portion of salt; then he adds the yeast, and then a certain quantity of flour. This mixture is set aside in a warm place, where it soon begins to ferment. This process is called *setting the sponge;* and according to the relation which the water in it bears to the whole quantity to be used in the dough, it is called whole, half, or quartern sponge. The evolution of carbonic acid causes the sponge to heave and swell; and when the surface bursts it subsides, and then swells again, and so on; but the baker is careful to use it before this fermentation has communicated sourness to the mass. He then adds to the sponge the remaining quantity of flour, water, and salt which may be required to form dough of proper quality and consistence, and incorporates the whole by long and laborious kneadings till the entire mass acquires uniformity, and is so tough and elastic as to bear the pressure of the hand without adhering to it. It is then left for a few hours, during which fermentation goes on; and the inflated mass is again kneaded, so as to break down any lumps or portions which had accidentally escaped diffusion in the first operation, and to confer perfect uniformity on the whole. The dough is then weighed out into loaves, which are shaped, and put aside in a warm place for an hour or two, during which they swell up to about double their original size; they are then put into the oven and baked; during which operation they again enlarge considerably in bulk, in consequence of the dilatation of the previously generated carbonic acid pent up in the dough; for, as soon as the mass is exposed to the heat of the oven, the fermentation is put an end to.

If we compare the baked loaf with the flour of which it is composed, we shall find that panary fermentation has produced a considerable change in the latter. The gluten and the starch, which (exclusive of a trace of sugar) were the components of the flour, have mutually acted upon and altered each other; the toughness and viscidity of the gluten is gone, and the starch no longer forms a gelatinous mixture with hot water; a little sugar is generally formed, as well as alcohol; but the principal cause of the change in the characters of the flour is the evolution of carbon and of oxygen in the form of carbonic acid, the production of which is independent of the presence of external oxygen (or of air). Small quantities of alum are also, it is said, invariably used by the London bakers, with the view of whitening or bleaching the bread; for it may be observed, that whatever may be the quality of the flour which is used, home-made bread is always of a comparatively dingy hue. According to Mr. Accum (*On the Adulteration of Food*), the requisite quantity of alum for this purpose depends upon the quality of the flour. The mealman, he says, makes different sorts of flour from the same kind of grain. The best flour is chiefly used for biscuits and pastry, and the inferior kinds for bread. In London no fewer than six kinds of wheaten flour are brought into the market; they are called fine flour, seconds, middlings, coarse middlings, and twenty-penny. Beans and peas are also, according to the same authority, frequently ground up with London flour. The smallest quantity of alum used is from three to four ounces to the sack of flour of 240 pounds.

Another article occasionally employed in bread making is carbonate of ammonia. As it is wholly dissipated by the heat of the oven, none remains in the baked loaf. It renders the bread light, and perhaps neutralizes any acid that may have been formed (exclusive of carbonic acid); but it is too dear to be much employed. To some kind of biscuits it gives a peculiar shortness, and a few of the most celebrated manufacturers use it largely. The French chemists have accused the bakers of employing sulphate of copper or blue vitriol, for the purpose of improving the colour of the bread; but so dangerous and easily detected an addition can scarcely be supposed to be common. According to Mr. E. Davy, bread, especially that of indifferent flour, is materially improved by the addition of a little carbonate of magnesia, in the proportion of twenty to thirty grains to the pound of flour; it requires to be very intimately mixed with the dough. The most nefarious adulteration of bread consists, however, in the addition of certain insipid and colourless earthy substances, with a view of increasing its weight; such as pipe-clay, porcelain-clay, chalk, and plaister of Paris. These, however, are probably very rarely resorted to; though in one instance the writer of this article had occasion to examine a quantity of *biscuits*, which were adulterated with gypsum to the amount of 10 *per cent.*

BREAK. (Teut. brache.) In Architecture, any projection from the general surface of a building.

BREA'KERS. Waves that break, or fall over, from the shallowness of the water. In a gale, the tops of the seas generally break in this way more or less, from the progressive motion of the water at the surface before the wind, which is exceedingly dangerous for open boats. This is never confounded with the falling over of the whole wave, as the surf falls over on the beach.

BREA'KING JOINT. In Architecture, that disposition of stones and bricks in their courses by which vertical joints are not allowed to fall over each other. *See* Diagrams to BOND, ENGLISH and FLEMISH.

BREAKWA'TER. An artificial bank of stones, or the hull of a vessel, sunk to break the sea before its entrance into a roadstead or harbour. The breakwater at Plymouth is a great work of this kind. It is built across the sound, which it completely defends from a very heavy sea from the channel in south-westerly winds, and which formerly caused the loss of many ships. It is composed of large stones dropt from vessels constructed for the purpose. The sea, which for a time offers serious obstacles to the construction, works the stones together, and washes up shingle and sand, which, with the growth of sea-weed, consolidate the whole. The outer mole of the harbour of Civita Vecchia, still in good repair, was formed by the Emperor Trajan exactly in the same way as the breakwater at Plymouth. (*Plinii Epist.* lib. vi. ep. 31.) The breakwater at Cherbourg, constructed by Napoleon, is one of the greatest modern works of this class.

BREAM. The name of a soft-finned fish, common it many of the lakes and rivers of England, and one that breeds freely and thrives in ponds, if there be sufficient depth of water. It is the type of a particular subgenus of the Carp family (*Cyprinidæ*), which Cuvier has characterized under the name of *Abramis*. *See* ABRAMIS.

BREA'MING. In Nautical language, signifies cleaning the bottom of a vessel by fire. When the vessel is aground, fire being applied to the bottom loosens the pitch, or composition of sulphur and tallow, with which the bottom is sometimes covered to defend it from the worms, and which is then scraped off, together with the barnacles, grass, weeds, &c. that adhere to it.

BREA'STING. Breasting up a hedge is cutting the face of it on one side, so as to lay bare the principal upright stems of the plants.

BREAST PLOUGH. A kind of spade or shovel, with a cross piece at the extremity of the handle, which is applied to the breast, and by which the operator skims off a thin slice of turf from a grassy surface, as if he were ploughing. Turf thus obtained is chiefly used in thatching.

BREA'STSUMMER. (From Sax. bꞃeoꞅꞇ, and summer; *quære*, trabs summaria?) In Architecture, a beam which supports an exterior wall, the beam itself being carried by wooden or iron posts.

BREAST-WORK. In Fortification, an elevation of earth thrown up round a fortified place to protect the garrison from the enemy's fire.

BRE'CCIA. (It.) A rock composed of an agglutination of angular fragments.

BREECH OF A GUN. The solid part behind the bore.

BRE'ECHING, or BREECH BAND. Part of the harness of a carriage horse, by means of which he is enabled to push the carriage to which he is attached backwards, or to support its pressure in going down a hill.

BREEZE-FLIES. *See* ŒSTRIDÆ.

BREHON LAWS. The ancient laws of the Irish are so termed, from an Irish word signifying *judges*. It is supposed that some of the numerous written collections of these laws which still exist are of great antiquity; as old, perhaps, as the earlier ages of the Christian era. Prior to the Anglo-Norman invasion, Ireland was entirely governed by these laws. For an account of the nature of these laws, see *Lord Lyttleton's Henry II.* vol. v. p. 28., and the authorities there referred to.

BRE'NTUS. A Fabrician genus of Coleopterous insects, belonging to the Weevil tribe, or *Curculionidæ*; now the type of a family, called *Brenthidæ*, including about eight genera and seventy species. These insects are peculiar to hot climates: only one species, the *Brentus Italicus*, is found in Europe, and this has been referred by Germar to a particular sub-genus, *Arrhenodes*, all the other species of which are natives of the new world.

BRE'TTICES. In coal mines, wooden plankings to prevent the falling in of the strata.

BREVE. (Ital.) In Music, a note formed thus 𝅜 without a tail, and equivalent to two semibreves, or four minims. It is also that measure of quantity contained in two beats of the hand up and two down, but this only in common time with the mark 𝄵.

BRE'VET. In the French, signifies a royal act in writing conferring some privilege or distinction; as brevet d'invention, a patent. It is applied, in England, to a commission giving nominal rank higher than that for which pay is received; thus, a brevet major serves and draws pay as captain, &c.

BRE'VIARY. A book containing the offices of daily prayer according to the usage of the R. C. church. The offices are seven; viz. matins, lauds, first, third, sixth, and ninth vespers, and the compline. Anciently all Catholics were required to recite the breviary daily. The injunction is now confined to the clergy; of whom it is still strictly exacted.

BRE'VIPENNATES, *Brevipennes*. (Lat. brevis, *short*; penna, *quill*; *short-quilled*.) An epithet applied by Cuvier to distinguish the first family of his order *Grallæ* (Echassiers); the ostrich is the type of this family. *See* CURSORES.

BREW'ING. *See* FERMENTATION.

BRI'BERY. In English Law, is a term comprehending the offences of judges, ministerial officers, &c., receiving rewards or considerations to act contrary to their respective duties, which are severally misdemeanors at common law, and also punishable under several statutes. But in its most ordinary signification, it is the giving or receiving money to procure votes at parliamentary elections, or elections to public offices of trust. The statutes which at present chiefly regulate the offence of bribery at parliamentary elections are 2 G. 2. c. 24., and 49 G. 3. c. 118. The latter statute imposes a penalty of 1000*l.* on any one (if not returned, incapacity to serve in parliament for that place if returned) who "shall give or cause to be given, directly or indirectly, any sum of money, &c., upon any engagement that the person receiving shall procure, or endeavour to procure, &c., the return of any member," and imposes a fine of 800*l.* on the person receiving the bribe on such a promise or agreement. The former makes it an offence in any person "to procure or corrupt another to vote;" and it has been recently held, that the corruption is complete, as far as the corrupter is concerned, by the act of giving the money, whether the voter intend or not to act according to the wish of the briber.

BRICK. (Dutch bricke.) In Architecture, a mass of clay earth, sometimes mixed with coal ashes, chalk, and other substances, formed in a mould, and burnt in a kiln or clamp. The earth used for this purpose is of two sorts. The one a stiff clay, with little or no extraneous mixture, which produces a hard red brick; the other a yellowish-coloured fat earth, called loam, which produces a grey-coloured brick. The clay is usually tempered in a clay mill. For the sea coal ashes that are mixed with it in London, they substitute in the country a light sandy earth. In making the paste as little water should be introduced as possible. In moulding them, which is done in a wooden mould, a clever workman will mould about five thousand in fifteen hours. The kiln in which they are burnt is a large building, about 13 feet long, 10 feet 6 inches wide, and 12 feet high, furnished with a proper furnace. When otherwise burnt, the *clamp*, as it is called, is formed of the bricks themselves, generally oblong on the plan, and the foundations made with place bricks. Each course of bricks is laid on a layer of *breeze* or cinders; and flues are formed, filled with coals, breeze, and wood. The burning continues from twenty to thirty days. The size of bricks, when burnt, is required by the statute to be 8¼ inches long, 2¼ inches thick, and 4 inches wide. The different varieties of bricks are, *malms*, which are of a yellowish uniform colour and texture; *seconds*, not quite so uniform in colour and texture as malms; *red* and *grey stocks*, the former being burnt in kilns, both of a quality rather inferior to seconds; *place bricks* or *peckings*, sometimes called sandel or samel bricks, which are those furthest from the fire, and rarely well burnt, — these should never be used in a building where durability is required; *burrs* or *clinkers*, which are masses of several bricks run together in the clamp or kiln from the violent action of the fire; *fire bricks*, of a red colour, about 9 inches long, 4½ inches broad, and an inch and a half thick, — they are made for use in furnaces to resist the action of the fire, and from having been formerly manufactured in the neighbourhood of Windsor, they are sometimes called Windsor bricks; *paving bricks*, made for the purpose their name implies; *compass bricks* are circular on the plan, chiefly used in walling wells, and the like; *Dutch clinkers* or *Flemish bricks*, chiefly used in stables; the Dutch clinker is 6 inches long, 3 inches broad, and 1 inch thick.

BRICKLA'YING. In Architecture, the art of building with bricks, which is of very great antiquity. Pausanias mentions many structures in Greece which were built of bricks; and in Rome such buildings were very common. The walls of Babylon, attributed by Herodotus to Semiramis, were also of brick.

BRICKNO'GGING. In Architecture, brickwork carried up and filled in between timber framing.

BRICK TRIMMER. (Sax. ꞇꞃımman, *to build.*) In Architecture, a brick arch abutting against the wooden trimmer in front of a fireplace, to guard against accidents by fire.

BRI'DEWELL. A house of correction for offenders is commonly so called in England. The name is derived from the locality of the ancient London house of correction, which was an hospital, founded by Edward VI. on the site of St. Bride's well, in Black Friars, a well-known object of pilgrimage in Roman Catholic times. The original Bridewell is under the control of the lord mayor, and used as a receptacle for vagrants, place of punishment for apprentices, &c., within the jurisdiction of the city.

BRIDGE. (Sax. bꞃıᵹᵹe.) In Architecture, a structure for the purpose of connecting the opposite banks of a river, gorge, valley, &c. &c., by means of certain materials, forming a roadway from one side to the other. It may be of stone, brick, iron, timber, suspended chains or ropes; or the roadway may be formed by means of boats. Long previous to the introduction of bridges constructed upon geometrical principles, the modes of crossing rivers by throwing the trunks of trees across them, or by suspension of ropes, or twisting together the branches of trees from bank to bank, were so obvious that they must have been resorted to at an early period. The former method, however, could only have been practised over narrow streams, whilst the latter might have been carried to almost any required extent. Mungo Park found this mode employed in Africa; and in South America rope bridges of bujuco, or thongs made from the hides of oxen, are in use at the present day. Don Antonio de Ulloa tells us, that over some of the rivers of Peru the bujuco bridges are of such dimensions that loaded mules in droves pass over them, and especially on the river Apurimac, forming the high road for the trade carried on between Lima, Cuzco, and other places to the southward. Though such bridges are the contrivance of man in a less civilised state, they are the only means by which many streams whose currents are deep and rapid can be crossed; and the stupendous suspension bridges of the present day are but improvements on the simple scheme of the untutored architect of a savage tribe. When a stream is neither deep nor rapid, its breadth seems to present no obstacle to forming a roadway over it. Large stones placed across at intervals, on which other stones or beams of timber may be laid horizontally, would be the first step. Of this species appears to have been the bridge which, according to Herodotus, Nitocris constructed at Babylon over the Euphrates, and which is said by Diodorus Siculus to have been five furlongs in length. Of this sort also are many of the bridges in China. The bridges of the Chinese, however, appear to have been rather too highly extolled in the accounts of Du Halde and the missionaries, as may be gathered from the information obtained of the Foo-chow-foo bridge, during the voyage of the ship Amherst in 1832. It appears, from the testimony of Captain Parish, that the use of the arch with wedge-shaped stones converging towards the centre of the curve must have been known to the Chinese at a very early period.

In tracing the history of bridges among different nations, we shall see that local causes had great influence on the species of construction adopted by them.

A nation may have reached the highest point of art in its other public monuments, and have nevertheless done nothing worthy of our admiration in the construction of a bridge. In Egypt, for example, intersected as it is by a large and wide river subject to periodic inundations, the construction of bridges would have been as difficult as it would have been useless. All the intercourse which commerce required was easily carried on by the assistance of boats; and as respects the passage over the canals which abounded in the country, their depth and breadth were so small as to require none but the most simple expedients for connecting their opposite banks, nor any which involved the employment of science. In Greece, no vestige of a bridge occurs whose date is anterior to its occupation by the Romans; but this, had they even been acquainted with the use of the arch, might be accounted for on reasons directly the reverse of those which operated in Egypt. Greece is intersected by no river of any magnitude; and even those which seem to have some title to the name, are rather mountain torrents than those immense sheets of water, swelled in their course by innumerable tributary streams, that are to be found in other parts of the world. Here scarcely more could be wanted than a single arch, whose abutments would be found in the solid rocks which the stream separated.

Following up the history of bridges into Italy, we find a country much watered by large rivers, where the architecture of bridges became a necessary study, not only for the accommodation of the cities with which it abounded, but also for the service of the frequent military expeditions of the restless conquerors who occupied its lands. Rome, from its earliest foundation, must have put in requisition considerable skill in bridge architecture over the Tiber, rapid and subject as it is to sudden floods. The earliest bridges here were of timber; such was that which joined the Janiculum to the Mons Aventinus, and was called the Pons Sublicius, from the *sublicæ* (stakes) of which it was formed. (*Liv.* i. 33.) Without enumerating the bridges of Rome, some of which are still standing to attest the science of their architects, we must mention the Pons Narniensis, on the Flaminian way, near Narni, and about sixty miles from Rome. It was built by Augustus; and vestiges of it remain to the present day, one arch above 150 feet span and 100 feet high being still entire. But of works of art, perhaps the most wonderful ever raised was the bridge built by Trajan over the Danube. It consisted of twenty piers, whose height from their foundation was 150 feet, and 170 feet apart; its breadth being sixty feet. This stupendous work was demolished by Hadrian, the successor of Trajan, under the pretence that it might serve as a passage for the barbarians, if they became masters of it; but some writers have said it was through envy of the fame that attached to its founder. Over the Tagus in Spain an ancient Roman bridge, near Alcantara, is still partly standing. It consisted of six arches of eighty feet span, extending altogether 600 feet in length, and some of the arches 200 feet high above the water. Of the temporary bridges of the Romans, the most famous was that of timber thrown by Cæsar over the Rhine.

From the fall of the Roman Empire to the revival of the arts, the history of bridge architecture is, with the exception of the Moorish works in Spain, of no interest. It appears from Gautier, who uses the authority of Mag. Agricola of Aix, that when the arts began to revive in Europe an order was founded by St. Benezet, under the title of Brethren of the Bridge; and that under them was begun, in 1176, the bridge at Avignon, consisting of eighteen arches, and about 3000 feet in length. During the contentions of the Popes in 1385 some of its arches were destroyed, and in 1602 three others fell. In 1670 the ice destroyed all but the third pier, which, with the Chapel of St. Nicholas upon it, still remains. In 1354 a bridge of three arches was constructed at Verona, the roadway sloping from the city: the largest of its arches, which are segmental, is 160 feet span; but a still larger arch was built at Vielle-Brioude in France, over the Allier, in 1454, of nearly 184 feet span, which is the largest stone arch upon record. Among the most celebrated bridges of Italy, is that of the Rialto at Venice, whose span is 98½ feet. It was begun in 1588, and finished in 1591, from the designs of Antonio dal Ponte (*Sansovino's Venice*), though by most authors absurdly attributed to M. A. Buonarroti. In this city alone there are no less than 339 bridges; but they are mostly of small spans. We must not omit in this place the bridge Della Santissima Trinità at Florence, by Ammanati, which, as Milizia truly observes, has not been surpassed since the revival of architecture. It is of three arches, the middle one of 96 and the two side ones of 86 feet span, the width of the piers being 26 feet 9 inches; the breadth of the carriage and footways between the parapets is 33 feet. It has been usual for writers to call the form of the arches of this bridge cycloidal; but from our own measurements and most particular investigation, we can assert that they are not of that form. They are very slightly pointed, after the fashion of what is called the Tudor arch of this country; the point at the summit, which is extremely obtuse, being hidden by the ram's head sculptured on the key-stones. During the two last centuries, the French have advanced their bridge architecture to very great perfection; but more particularly in the latter part of the last century, in which appeared Perronet, the father of the modern system of the art, whose elegant designs have not since been improved upon either in France or any other country. His is the beautiful bridge of Neuilly over the Seine. It consists of five arches, each about 128 feet span and 32 feet rise: it was finished in 1774, and remains a splendid monument of the powers of its architect. Some of the more modern specimens of their bridges do great honour to the French school, in which beauty of form is united with sound engineering.

In England, the progress of bridge architecture has kept pace with that of the Continent; and if our bridges cannot boast the elegance in design of our lively neighbours, we are fully equal to them in boldness of conception and execution of the work. Indeed, if the designs of the late Messrs. Telford and Rennie had been equal to their engineering skill, no country in the world would have been able to compete with what we should have been able to exhibit. And here must not be forgotten the bridge over the river Taaf, near Llantrissart, in Glamorganshire, celebrated for its great span; the work of William Edwards, a country mason, in 1755. The chord line is 140 feet, and the versed sine 35 feet. As we can allow but short space for an account of the bridges which within the last eighty years have been built in this country, we must be content with the mention of that over the Thames, called the Southwark bridge, which is a stupendous exhibition of engineering skill, and far better in design than many of the other works of the late Mr. Rennie. This bridge is of cast-iron, and consists of three arches, the chord of the centre arch being 240 feet, and its versed sine 24 feet, or one tenth of its span. The frame-work of the arch at the vertex is 6 feet in height. We are not aware of any cast-iron bridge whose dimensions exceed those of this bridge, and do not think it therefore necessary to mention minor ones, of which there are many fine specimens in Great Britain.

Of timber bridges the boldest and most ingeniously constructed in Europe was that at Schaffhausen, in Switzerland, destroyed by the French in 1799. It was designed and executed by Ulric Grubenmann, a common carpenter of Tueffen, in 1758. The total length of this bridge was 364 feet, but it was relieved by a pier in the middle of the river. In America are some extraordinary specimens of timber bridges. Such is the Trenton bridge, over the Delaware, built in 1804, by Burr: its chord line is 200 feet, and its versed sine 32 feet, the height or thickness of the timber framing at the crown being only 32 inches. The bridge called the Colossus at Philadelphia, over the Schuylkill, is 340 feet span, with a versed sine or rise of only 20 feet, and the thickness of the timber at the vertex only 7 feet. It is the work of a person named Wernwag. Besides these two, there are many other timber bridges in America worthy the notice of the reader, which we regret we have not space to notice.

We shall close this portion of our subject by a short account of the suspension bridge over the Menai Strait, by the late Mr. Telford, as being the giant of its species, and rendering unnecessary any enumeration of others. It consists of one opening of 560 feet between the points of suspension, the height between high water and the under side of the roadway being 100 feet. The platform is 30 feet in breadth. The whole is suspended from four lines of strong iron cables by perpendicular rods 5 feet apart. On the tops of the pillars the cables pass over iron rollers, and are fixed under ground to iron frames, which are retained in their places by masonry. The weight of the whole bridge between the points of suspension is 489 tons. In Suspension bridges it has been found that the most trying circumstances under which they can be placed, as affecting the stability of their equilibrium, is the heavy and measured tread of a long line of infantry, whose feet drop at the same instant of time.

In the building of bridges, where piers are required in the stream for the support of the arches, it is important to place them as nearly as possible at right angles to the stream or current; and the piers should be made convex towards the stream, for their better resistance to floods. The position of a bridge moreover, should not be in a narrow part, nor one liable to swell with tides or floods, inasmuch as the contraction of the waterway increases the depth and velocity of the current, and may thus endanger the navigation as well as the bridge itself. It is usual to construct bridges with an odd number of arches, and this on several accounts; among which are, that the stream being usually most

powerful in the middle, an egress through that part is best provided for by having a central arch; and again, if the bridge be not perfectly horizontal, symmetry is gained by rising from the sides to the centre, and the whole roadway may be made one continued curve. When a bridge is equally high throughout, much saving of centering is made, because the arches being all equal two sets of centres will be sufficient. If, however, the bridge be higher in the middle than at the extremities, the arches on each side the centre one must diminish similarly, so as to be respectively symmetrical; and by this arrangement beauty is gained, and the centering for one side equally suits the other. It is desirable to construct a bridge with as few arches as circumstances will allow, that there may be a free passage for the water, as well as for the vessels that have to pass up and down, not to mention the saving of materials and labour where there are fewer piers and centres. When a single arch can be compassed, no more should be permitted. (For the mode of estimating the equilibrium of an arch, see the article ARCH.) The piers should be of sufficient solidity to resist the thrust or push of the arch, independent of other arches, so that the centering of an arch may be struck without danger of overturning the pier left naked; and the piers should also be spread as much as possible on their bases, and diminish gradually upwards from their foundations. The method of laying the foundations in a river is now usually by means of coffer-dams, which are large enclosures, made by piling round the space to be occupied by the pier, so as to render it water-tight, and then pumping out the water, and keeping the space dry till the pier is built up to the ordinary level of the water; but if the ground about be loose, this method cannot well be practised, and recourse is had to caissons, which are a species of flat-bottomed boat, in which the pier is built up to a certain height, and then sunk over the place where it is intended to remain, the bed of the river being dredged out to receive it, or piles driven on which it may lodge when the sides of the chest or caisson are knocked away In constructing the centres great care must be taken to make them incapable of bending or swerving while the arch is being turned, otherwise the form of the arch will be crippled. We here subjoin a table of some of the most celebrated bridges in Europe, chiefly in reference to their dimensions, and the relative spans and heights of their arches.

BRI'DGING JOISTS. *See* JOISTS.

BRIEF. (Lat. brevis, *short.*) A word applied originally to a small written scroll; but it is used at present in several significations. In modern German the word brief signifies a letter.

1. In Ecclesiastical Law, letters addressed from the pope to temporal princes or communities on subjects of discipline or public affairs, are termed apostolical briefs. The name appears to have originated either in the concise formula with which they begin ("dilecto filio salutem et apostolicam benedictionem"), or in the difference that exists between this smaller kind of instrument and the ample bullæ (bulls) of the popes. Apostolical briefs are usually written upon paper, though sometimes parchment is used. They are sealed in red wax with the seal of the Fisherman (sub annulo Piscatoris), which is a symbol of St. Peter casting a net into the sea. (*Ciampini, Dissertatio de Abbrev. Munere*, cap. iii.)

2. In Law, the term brief is applied to an abridged narration of the facts of a case prepared for trial, with or without a reference to points of law involved in it, drawn up for the preliminary instruction of an advocate.

3. The term brief is applied in England to king's letters, issued to the archbishops, bishops, clergy, magistrates, and parochial officers, to authorize collections of money at the doors of the several churches and chapels throughout the country, in individual cases wherein application has been made for such assistance towards the building or repair of a particular church. This custom is supposed to have commenced after the disuse of papal briefs consequent on the Reformation. Within the last few years this practice has been dropped, and a king's letter is sent round at certain intervals to collect money for the use of the Incorporated Society for the Building of Churches generally throughout the country. The last collections were made in 1829, when something more

than 40,000*l.* was received; and in 1834, when the sum collected amounted to rather more than 30,000*l.*

BRIG. The general term for a vessel having two masts, with a boom mainsail, being otherwise square-rigged; that is, having her sails brought to yards hung horizontally by the middle.

BRIGA'DE. This term either implies the union of two or more regiments or battalions in one corps, or of a certain number of men or guns in one subdivision. A brigade of infantry may consist of from one to six battalions, and a brigade of cavalry of two or three regiments. Six pieces of ordnance form a brigade of artillery; and the horse artillery consists of twelve troops, to each of which is attached one such brigade of guns. A brigade of sappers consists of eight men. The commander of a brigade is called a brigadier-general.

BRI'GANTINE. A name often applied to a small brig of a foreign nation.

BRIGHT. (Sax. beorht.) In Painting, shining with light; a term applied to a picture in which the lights preponderate over the shadows.

BRILLA'NTE. (Ital.) In Music, prefixed to a movement, denotes that it is to be played in a gay and lively manner.

BRI'MSTONE. *See* SULPHUR.

BRI'STOL STONES, BRISTOL DIAMONDS. These are small and brilliant crystals of quartz, found in the vicinity of Bristol, and occasionally used for ornamental purposes.

BRI'TISH GUM. When starch is exposed to a temperature of about 600° it becomes of a brownish colour, and so far altered in its chemical characters as no longer to form a blue colour with iodine; it is also soluble in cold water. In this state it is used, under the above name, by calico printers.

BRO'ADCAST. Sowing seeds by casting them or scattering them abroad, so as to distribute them evenly over the entire surface of the soil, in opposition to sowing in drills or rows. The operation of sowing broadcast is generally performed by the hand, the operator carrying the seeds in a bag or sowing sheet, or in a basket. There are also machines for sowing broadcast, but they are not much in use. In general, all corns and grasses are sown broadcast; while pulse, and broad-leaved plants grown for their roots or leaves are sown in drills or rows. The term is sometimes applied to planting, but it is more generally restricted to sowing.

BRO'ADSIDE. A nautical term, signifying the discharge of the whole of the artillery on one side of a ship of war.

BRO'KEN-BACKED. A ship is said to be broken-backed when, in consequence of being loosened from age or injury, her frame droops at either end.

BRO'KEN-WINDED. A ruptured state of the air cells, chiefly on the edges of the lungs, in the horse, in consequence of which the expiration occupies more time than the inspiration of the air, and is laboriously and generally spasmodically effected. It is a disease which may admit of palliation, but not of cure; the animal becomes gradually less capable of exertion, and if urged on, he drops and dies.

BRO'KER. In Mercantile Law, a person employed about contracting for the disposal of property without being put in actual possession of it, as is the case with a factor. (*See* FACTOR.) But all agents answering to this definition are not brokers, nor has the term any very exact legal signification. Particular classes of brokers are, bill or exchange brokers, stock brokers, insurance brokers, pawnbrokers, and brokers who sell or appraise household furniture for rent. By 8 & 9 W. 3. c. 20. brokers in the city of London must be licensed by the mayor and aldermen, and grant a bond with a penalty of 500*l.* on their admission. According to mercantile usage, if goods within the city of London are sold by a broker to be paid for by a bill of exchange, the vendor, if not satisfied with the solvency of the purchaser, has a right within a reasonable time to annul the contract.

BRO'KERAGE. The per-centage paid the broker for his trouble in effecting a sale, or in negotiating any particular business.

BROME'LIA'CEÆ. (Bromelia, one of the genera.) A natural order of Endogenous plants inhabiting the tropical parts of the world, where they grow in the rich vegetable soil of forests, or upon the branches of trees, to which they cling by their twisting slender roots. They usually have hard leaves covered with a scurfiness easily rubbed off, and are so arranged as to be able to hold the water that lodges in their centre. Many of them will grow for months, and flower, when suspended in the air, after being severed from their roots. Their flowers are usually white, crimson, blue, or purple, and often exceedingly handsome. In the genus *Ananassa* the bracts and flowers are so fleshy, that they all grow together into a solid mass, and thus form the well-known fruit called the pine apple. *Tillandsia usneoides* is a curious species of this order, hanging down in long grey threads from the branches of trees in American forests, and so seldom flowering that it might be taken for some species of lichen; it is easily dried, and then used for stuffing mattresses, &c.

BROMINE. (Gr. βρωμος, *a strong odour.*) An undecompounded substance discovered in 1826 by M. Balard of Montpelier. In its general chemical habitudes it much resembles chlorine and iodine, and is generally associated with them. It exists, but in very minute quantities, in sea-water, and in the ashes of marine plants. It is usually extracted from *bittern* by the agency of chlorine. At common temperatures it is a very dark reddish liquid, of a powerful and suffocating odour, and emitting red vapour. Its specific gravity is about 3. It boils at 116°, and congeals at 4°. The density of its vapour is 5·5; 100 cubic inches at mean temperature and pressure weighing 167·25 grains. It is an electro-negative; it has bleaching powers, and it is very poisonous. Its equivalent number is about 78; it combines with hydrogen to form *hydrobromic acid gas*, 100 cubic inches of which weigh 84·7 grains. With oxygen it forms the *bromic acid.* Its combinations are termed *bromides;* they have not hitherto been applied to any use, but some of them are probably possessed of powerful medical qualities.

BRO'NCHIA. (Gr. βρογχος, *the throat.*) The smaller ramifications of the windpipe.

BRONCHI'TIS. Inflammation of the bronchia.

BRONCHOCE'LE. (Gr. βρογχος, *the throat,* and κηλη, *a tumour.*) A tumour on the fore part of the neck, being a morbid enlargement of the thyroid gland. From its prevalence in Derbyshire it is sometimes called the *Derbyshire neck*, and it is a very common disease among the inhabitants of mountainous districts, especially of the Alps. It has been attributed to some peculiarity of the water of those districts, but upon no satisfactory evidence. Iodine has lately been administered successfully in the cure of this and other glandular enlargements, but it is a medicine requiring to be used with caution.

BRONCHO'TOMY. (Gr. βρογχος, and τεμνω, *I cut.*) The operation of making an opening into the trachea in order to prevent suffocation.

BRONZE. (It. bronzo.) In Sculpture, a material used for casting statues, groups, &c., in a mould similar in principle to that wherefrom all plaister casts are produced. From the extraordinary dimensions which involve the chief differences between the operations of casting in brass and plaister, much intelligence and care on the part of the sculptor is necessary to produce the fac-simile of the work on which his labour has been expended. The material employed for the purpose is a compound chiefly consisting of copper, tin, and other metals. The process of procuring the cast depends on circumstances requiring much nice arrangement; but the reader will immediately conceive that though the difficulty of making such a mixture insinuate itself into every part of the often colossal mould is great, it is no more in reality than many of the large cast-iron foundings which are every day effected; though, from the nature of the human and other animal forms, it is difficult to conduct such an operation with any thing like a degree of certain attainment of the object without extraordinary means.

BRO'NZITE. A variety of diallage of a metallic or *bronze* colour.

BROOM. The *Spartium scoparium* or *Cytisus scoparius* of botanists, is an evergreen, green-branched shrub, native of sandy soils throughout Europe. It is sown extensively in this country as a shelter for game, and among the other plants in young plantations as a screen from the wind and a protection till the more important species can establish themselves. Its branches, which are tough, are made up into brooms, to which they have given their name.

BROWN. (Sax. brun.) In Painting, a dark dusky colour inclining towards red, of various degrees of depth, of which there are many sorts.

BROWN COAL. An imperfect kind of coal, which burns with a peculiar bituminous odour resembling that of peat. Its ligneous structure is sometimes so distinct that it has been called *bituminous wood.*

BROW'NISTS. The followers of Robert Brown, who in the year 1581 seceded from the English church, and established a sect upon the principle that every congregation should form a church independent (in matters of discipline and doctrine) of all others. In matters of doctrine he did not differ from the church; to which indeed he returned, and took preferment after some years. The Brownists underwent great persecution under Elizabeth, and retired in considerable numbers to Holland. From them, however, have sprung the Congregational Brethren and Independents, a very powerful sect in England at the present day. *See* INDEPENDENTS.

BROWN SPAR. A magnesian carbonate of lime tinged by oxide of iron and manganese.

BRU'CHUS. A Linnæan genus of Coleopterous insects, of the tribe *Rhyncophora*, now the type of a family (*Bruchidæ*), with the following characters: — upper lip distinct; head produced anteriorly into a broad flattened snout; palpi filiform; antennæ filiform or serrate; eyes notched; wing-sheaths not covering the extremity of the

body. The insects of this family deposit their eggs in the young grains or seeds of leguminous plants; the time of the hatching of the eggs is when the seeds have approached to maturity, and then the larvæ begin to feed voraciously upon them. One species, the *Bruchus granarius*, infests our peas; and the ravages of this insect, and the *Bruchus pisi*, have been so extensive as to call for legislative inteference: in France, for example in the year 1780, the sale of peas in the market was prohibited, in consequence of the damaged and unwholesome condition of those vegetables through the operations of the species of *Bruchidæ* above cited.

BRU'CIA. A vegeto-alkaloid, discovered by Pelletier and Caventou in the bark of the *Brucea antidysenterica;* and also associated in small relative proportion with *strychnia* in the nux vomica and St. Ignatius's bean. It is very bitter and poisonous.

BRU'NSWICK GREEN. A pigment obtained by exposing metallic copper to the action of muriate of ammonia. It is a compound of chloride and oxide of copper. Is is also generated by the action of sea water upon copper, as in the green matter which incrusts the copper sheathing of ships.

BRUSH. (Fr. brousse.) In Painting. *See* PENCIL.

BRU'TA. The term by which Linnæus designated an order of Mammals, including the elephant, manatee, and walrus, with the quadrupeds now forming the order *Edentata* of Cuvier.

BRYO'NIA. A bitter and somewhat poisonous principle, extracted from the root of the *Bryonia alba.*

BR'YONY. (Gr. βρυω, *I grow rapidly.*) A wild climbing plant belonging to the Cucurbitaceous order, with a large woody perennial root, and annual stems, which resemble those of a gourd, except that they are more slender, clinging to bushes by means of their twisting tendrils. The berries are scarlet, with a disagreeable odour when bruised. The leaves have five angular lobes, and are three or four inches broad, with many callous tubercles. The roots are violently purgative: they are now disused. It has been known to produce violent vomiting, tormina, profuse watery evacuations, and fainting. Cases are mentioned by Orfila and others where over doses have proved fatal. Bryonine, an active extractive principle, is among the most dangerous of vegetable poisons.

BU'BO. (Gr. βουβων, *the groin.*) A tumour very frequently occurring in the glands of the groin, and also in the arm pit. It is often the result of local absorption of irritating matter, as in venereal buboes; or is symptomatic of constitutional disease, as in the plague, scrofula, and some fevers.

BUBONO'CELE. (Gr. βουβων, *the groin*, and κηλη, *tumour.*) A rupture forming a tumour in the groin.

BU'CCANEE'RS. (Fr. boucanier, from boucan, a word of the Caraïb Indians, signifying meat preserved in a particular manner, which was adopted, together with the custom, by the French in the West Indies.) The pirates who infested the coasts of the West Indies and South America during the 17th and 18th centuries were so called. The association of these pirates is said to have commenced as early as the middle of the 16th; but in 1625 they obtained possession of St. Kitt's, and afterwards of Tobago, which thenceforward became for a long time the head quarters of the buccaneers, who formed a sort of seafaring republic, composed chiefly of English and French adventurers. Their chief object was war against the Spaniards, and plunder of their ships and settlements. After the peace of Ryswick, in 1697, they gradually disappeared from the seas. The *History of the Buccaneers of America*, by James Burney, is a well known and entertaining work. By French writers these pirates are commonly called *Flibustiers*, apparently a corruption of the English word *freebooters.*

BUCCINA'TOR. (Lat. buccina, *a trumpet.*) A muscle of the cheek called into action in various motions of the mouth, and especially in blowing a wind instrument.

BU'CCINUM. (Buccinum, *a trumpet* or *shell-fish.*) The name of a Linnæan genus of Vermes Testacea, characterized by having a shell with a smooth non-plicated columella, and with a fissure or short respiratory canal inflected towards the left. The mollusca with shells corresponding to this character are ranked amongst the Pectinibranchiate Gastropods by Cuvier, and have been subdivided into the following subgenera: —*Buccinum* proper, Brug., of which the whelk, *Buc. undatum*, is an example; *Nassa*, Lam.; *Eburna*, Lam.; *Ancillaria*, Lam.; *Dolium*, Lam.; *Perdix*, Mart.; *Harpa*, Lam.; *Purpura*, Brug.; *Monoceros*, Lam.; *Ricinula*, Lam.; *Concholepas*, Lam.; *Cassis*, Brug.; *Morio*, Montf.; *Terebra*, Brug.

BU'CCO. (Lat. bucca, *cheek.*) The name of a genus of Lygodactyle birds, called barbets. The scientific term relates to the tumefaction of the sides of the base of the bill; the trivial English name is derived from the bristly feathers which surround the base of the bill, and project beneath the chin like a beard. The genus is now the type of a family, including the barbets proper (*Bucco*), the Brazilian barbets or tamatias (*Tamatia*), and the barbicans of Buffon, which are limited to the warmer parts of India and Africa.

BUCENTAU'R. (Gr. βους, *an ox;* κενταυρος, *a centaur.*) A mythological monster, half man and half ox, as the Greek etymology of the word imports. This was also the name of the state galley of the Venetian doges, in which they annually sailed over a portion of the Adriatic on Ascension Day, and, dropping a ring into the sea, espoused it in the name of the republic, with the words, "Desponsamus te, mare, in signum veri perpetuique dominii."

BU'CEROS. (Gr. βους, *an ox*, and κερας, *a horn.*) A genus of Syndactylous Insessorial birds, remarkable for the prodigious size of the mandibles, the superior of which in some species supports a large horn-like protuberance. The birds of this genus are commonly called horn-bills; they are peculiar to the old world, and perform the same offices in wild nature as the toucans of America.

BU'CKA. A strong-smelling leaf imported from the Cape of Good Hope, and used medicinally as an antispasmodic. It is produced by *Diosma crenata* and some allied species.

BU'CKWHEAT. (A corruption of beechwheat.) A kind of grain, produced by the *Polygonum fagopyrum* of botanists. It has a triangular form, and is not unlike beechmast. In some countries it is cultivated as food for man, and even in this country its flour is said to enter into the composition of the thin cakes called crumpets; but its chief value is as food for pheasants, which are so fond of it that they may be decoyed from their preserves by its employment. It is said that some estates have been rapidly stocked with this description of game, at the expense of the neighbouring coverts, by the aid of a few fields of buckwheat.

BUCO'LICS. The Greek term for pastoral poems, meaning literally the songs of herdsmen (βουκολοι). We have considerable remains of this species of poetry in the poems of Theocritus, Bion, and Moschus, and the Eclogues of Virgil. The metre universally employed is the hexameter or heroic; but in pastoral poetry an easier flow of the lines was studied than in epics, and this was generally accomplished by introducing a larger proportion of the metrical feet called dactyls in the former than in the latter; but no rules were laid down on this point. This species of poetry has been cultivated also by most modern nations, and in England, France, and especially in Germany, with great success. Indeed, the last-mentioned country can boast among others of a Gessner, whose Idyls have been pronounced by some modern critics to be models of pastoral poetry, combining the most finished harmony of numbers with a simplicity and tenderness of sentiment and expression worthy of Theocritus himself.

BU'DDHISM. A religion which prevails over a great part of Asia; and, according to the estimates of some geographers, has a much greater number of worshippers than any other form of faith among mankind. China, the peninsula beyond the Ganges, Japan, and various Indian islands, are chiefly peopled by Buddhists. The founder of this religion, according to tradition, was an Indian prince, to whom the title of Buddha, or "The Sage," is assigned by his worshippers. The period to which his life is assigned is variously estimated, according to a variety of oriental traditions; but several of them coincide in referring it nearly to the tenth or eleventh century before Christ. Buddhism was expelled from India by the persecutions of the Brahmans, between the fifth and seventh centuries of our era. The doctrines of the Buddhists seem mainly to rest on the principle, that the world, and sensible objects contained in it, are manifestations of the Deity, but of a transient and delusive character; that the human soul is an emanation from Deity; that after death it will again be bound to matter, and subjected to the miseries and accidents of this life, unless the individual to whom it belongs by the attainment of wisdom through prayer and contemplation succeeds in liberating it from that necessity, and secures its absorption into that divine essence from which it sprang.

BU'DGET, in a general sense, means a condensed statement of the income and expenditure of a nation, or of any particular public department. In this country, however, the term is usually employed to designate the speech made by the chancellor of the exchequer when he gives a general view of the public revenue and expenditure, and intimates whether government intend to propose the imposition or repeal of any taxes, &c.

BU'FFALO. (Lat. bubalis.) A term originally applied to a species of antelope; but afterwards transferred, in the age of Martial, to different species of the ox. In modern zoology the Buffaloes, or the "Bubaline group" of the genus *Bos*, include those species which have the bony core of the horn excavated, with large cells or sinuses communicating with the cavity of the nose; the horns are flattened, and bend laterally with a backward direction, and are consequently less applicable for goring than in the Bisons,

or Taurine group of oxen: the head is large, with a narrow but convex forehead, and terminates in a broad muzzle. The Buffaloes are of large size, but low in proportion to their bulk; they have no hunch on the back, and only a small dewlap on the breast: the hide is generally black; the tail long and slender. The Buffaloes occupy the warm and tropical regions of the earth; they avoid hills, and prefer the coarse vegetation of the forest and swampy regions to those of open plains; they love to wallow and lie for hours sunk deep in water; they swim well, and cross the broadest rivers without hesitation; their gait is heavy, and they run almost always with the nose horizontal, being principally guided by the sense of smelling. In their combats, they usually strike or butt with the forehead, and when their opponent is thrown they endeavour to crush him with their knees; they trample on the body; and their vindictive fury is so lasting, that they will return again and again to glut their vengeance upon the same inanimate corpse: they herd together in small flocks, or live in pairs, but are never strictly gregarious in a wild state. The females bear calves two years following, but remain sterile the third; they propagate at four and a half years old, and discontinue after twelve. Their extreme aversion to red colours has been remarked both in India and at the Cape. The Arnee Buffalo (*Bos Arni*) is the species in which the horns attain the greatest size: there is a pair of horns in the British Museum considered by Col. Smith (from whose excellent description of the Ruminantia in the translation of the *Animal Kingdom* of Cuvier the preceding observations are chiefly derived) to be of the true or Great Arnee: each of these horns measures along the curve from base to tip, six feet three inches; circumference at the base, eighteen inches.

BUG. *See* CIMEX.

BU'GLE HORN. (From bucula, *a heifer*.) A musical wind brass instrument, latterly improved by keys, so as to be capable of all the inflexions of the scale.

BUHL. Ornamental furniture, in which tortoise-shell and various woods are inlaid with brass. The name is derived from its inventor.

BULB. (Gr. βολβος.) A collection of fleshy scales, arranged like those of a bud, of which the bulb is a slight modification, separating spontaneously from the stem to which it belongs, and emitting roots from its base. It is usually found underground, as in the hyacinth; but sometimes upon the surface of the stem in the axils of the leaves, as in the bulbiferous lily. The old botanists used to distinguish two sorts of bulbs, the tunicated and the solid: the former is the only one to which the name is now applied; the latter is the cormus, as in crocus.

BULBO'DIUM. A kind of underground stem, resembling a rhizoma.

BU'LBOGE'MMA. A name for those bulbs which grow on the stems of plants, as in the tiger lily and other species of that genus.

BU'LBOTU'BER. That kind of stem which the old botanists called a solid bulb, and the moderns more generally a cormus. It is a round solid underground stem, clothed with the withered remains of leaves, and producing buds on its surface, as in crocus.

BU'LE. (Gr. βουλη, *a council.*) By this name the Athenian senate was designated, the constitution of which was as follows:—When the people were divided into four tribes, each of these, according to the regulation of Solon, elected 100 representatives, thus making in all a deliberative body of 400 members. But when Cleisthenes increased the number of tribes to ten, the complement of the senate was raised to 500, fifty of which were sent by each tribe; when the tribes were finally increased to twelve, 100 more senators were added. All free-born Athenian citizens above thirty years of age were eligible to this office; but they were obliged to undergo a strict examination of their characters and morals. The senate was originally instituted by Solon to be a check on the assembly of the whole people (εκκλησια), before which, according to the Athenian constitution, no measures were allowed to be brought before they had first met with its approbation. *See* PRYTANES.

BULI'MIA. (Gr. βου, a syllable denoting *greatness* in compound words, and λιμος, *hunger*.) A morbid appetite for food.

BULKHEAD. The sea term for any partition, as of wood, canvass, or other material.

BULL, PAPAL. (Lat. bulla.) An instrument, ordinance, or decree of the pope, equivalent to the proclamations, edicts, letters patent, or ukases of secular princes. Bulls are written on parchment, to which a leaden seal is affixed, and are granted for the consecration of bishops, the promotion to benefices, and the celebration of jubilees, &c. The publication of papal bulls is termed fulmination; and it is done by one of three commissioners, to whom they are usually addressed. The bull is thus described by Matthew Paris:—Anno Dom. 1257. In bulla domini Papæ stat imago Pauli a dextris crucis in medio bullæ figurata, et Petri a sinistris.

BULL, GOLDEN. In German History, a term applied particularly to a statute or enactment of the emperor Charles IV., published A. D. 1356, in two diets held in succession at Nurimberg and Metz, for the purpose of fixing the laws in the election of the emperor, and of regulating the number and privileges of the electors. (Churfürsten.) The original copy of this instrument (which was long regarded as the Magna Charta of the German Empire, and continued in operation till its dissolution in 1806) is preserved at Frankfort on the Maine, and has a seal of gold appendant; whence the appellation Golden Bull is derived.

BU'LLA. (Lat.) A stud or boss, but more particularly an ornament in the shape of a heart, worn round the neck by noble Roman children till they were seventeen years old; when they assumed the manly dress of the toga, and suspended the bulla as a consecrated offering to the *lares* or household gods.

BU'LLA. (Lat. bulla, *a bubble*.) A genus of Acerous Gastropodous Mollusks, the shell of which is more or less globose, or inflated like a bubble; having no visible or projecting spire, which is concealed by the large external whorl, which is elevated above the rest. The columella makes a convex prominence, which gives a crescentic form to the aperture of the shell; the animal breathes by gills, but has no respiratory tube or siphon, and consequently the margin of the aperture of the shell is entire, or without a fissure or canal. All the species of bulla are remarkable for a shelly apparatus of three pieces which converts the stomach into a gizzard or triturating cavity. These gastric calcareous pieces have been described as a bivalve shell of a new genus.

BU'LLETIN. (Mod. Lat. bulleta.) In Diplomatics, a term equivalent to schedule, and variously applied to different sorts of public acts. In modern times, this name has been applied, especially in France, to reports of a state of facts issued by authority; as bulletins of health, bulletins of military events, &c.

BU'LLION. Uncoined gold and silver.

BULL'S EYE. In Architecture, a small circular opening or window.

BULL'S NOSE. In Architecture, the external angle of a polygon, or of two lines which meet at an obtuse angle.

BU'MBOAT. A boat allowed to attend a ship regularly to supply the sailors with articles of provisions, clothing, &c.

BUOYS. Vessels formed of wood, cork, or some light substance, moored or anchored so as to float over a certain spot, in order to indicate the situation of a shoal or sand bank, and mark out the course a ship is to follow. When used for this purpose, buoys are usually close vessels in the form of a cone, of large dimensions, in order that they may be seen from a distance; and generally painted of some particular colour, in order that they may be more readily distinguished from one another. Public buoys in this country are placed by warrant of Queen Elizabeth under the management of the Corporation of the Trinity House, and the amount of revenue annually collected for their use is between 11,000*l.* and 12,000*l.* Private buoys are used for the purpose of indicating the situation of ships' anchors (to which they are fastened by a rope), in order that the ship may be prevented from running foul of the anchor, and that the anchor and cable may be recovered when the latter happens to be broken, or has been cut.

BU'PHAGA. (Gr. βους, *ox*; φαγω, *I eat*.) A genus of Conirostral Passerine birds, of which the African beef-eater (*Buphaga Africana*) is the sole example. It derives its name from its habit of sedulously extracting from the backs of cattle the larvæ of æstri and other Dipterous insects which are deposited therein. The French name of this bird, "pique-bœuf," or "cattle-picker," more correctly denotes the peculiar habits of the bird than the scientific generic term.

BUPRE'STIS. (Lat. buprestis, *a noxious insect*.) The name of a Linnæan genus of Coleopterous Serricorn insects, now the type of a family (*Buprestidæ*), including the most splendid and brilliant beetles. Of this family upwards of a thousand species are known: by the French they are termed "Nichards."

BU'RDEN. (Fr. bourdon, *a staff*.) In Music, the drone or bass in some musical instruments, and the pipe or string that plays it. The bass pipe in the bagpipe is so called. Hence, that part of a song that is repeated at the end of every stanza is called the burden of it.

BUREAU'. (Fr.) Originally a writing table; afterwards applied to the office of any public or private functionary where business is transacted.

BUREAU'CRATIE, or BUREAUCRACY, is the system by which the business of administration is carried on in departments, each under the control of a chief, in contradistinction to those systems in which the officers of government have a co-ordinate authority.

BURE'TTE. An instrument occasionally used in the chemical laboratory, and in the assay office, for the purpose of dividing a given portion of any liquid into 100

or 1000 equal parts. (*Gay Lussac*, *Instruction sur l'Essai des Chlorures de Chaux.*)

BU'RGAGE TENURE. In Law, an ancient tenure proper to boroughs; under which tenements are held of the king, or other person, at a rent certain. In several boroughs such holdings conferred the electoral franchise previous to the Reform Act.

BU'RG-GRAVE. (Germ. burg, *castle;* graf, *count.*) In the German Empire, a castellan or lord of a castle, having the right of private justice, imposing taxes, &c.

BU'RGHERS and ANTIBURGHERS. In Ecclesiastical History. Owing to an undue exercise of patronage, which took place under the authority of the church of Scotland, or to the induction of a clergyman into a parish (Kinross) against the declared sentiments of the congregation, a schism took place in the church, which occasioned a secession from that establishment, and ultimately led to what is called the Burgher and Antiburgher denominations. Several clergymen, after years of painful discussion, having protested against the violent procedure in question, and having thrown off subordination to the ecclesiastical authorities, were deposed (1740) from the office of the ministry and their parishes declared vacant. (*Gillan's Acts of Assembly*, sect. *Patronage.*) These clergymen, eight in number, though cut off from all connection with the church, enjoyed the unabated confidence of their respective congregations, who almost to a man adhered to them. Previously to their final separation from the establishment, namely, in 1733, four of that number had virtually proclaimed their independence, and had constituted themselves into an ecclesiastical court, called the *Associate Synod.* To the deposed ministers and their adherents the name of *Seceders* was applied; and hence the origin of the *Secession Church* in Scotland. And so rapidly did this body increase, that so early as 1745, they formed themselves into a synod, which consisted of three different presbyteries. But while their numbers were thus augmented, and while the sphere of their influence was rapidly extending, a breach took place among themselves, which was characterized by as much agitation and violence as that which had recently caused their ejection from the established church. The Secession Synod having instituted an inquiry into the lawfulness of certain oaths, not imposed by parliament, but generally practised, a question arose as to the nature of the oath imposed in royal burghs on persons when admitted to the privileges of a burgess. The great point of debate was, whether it was lawful for a Seceder to swear the following clause: — "I profess and allow with my heart the true religion presently professed within this realm, and authorized by the laws thereof. I shall abide thereat, and defend the same to my life's end, renouncing the Roman religion called Papistry." The Synod was divided into two parties on this subject. The one contended, that though they had condemned the manner in which the established church was at present administered, they had not expressed and did not feel any objection to her standards; that, in seceding, they had not set up a new religion, but that, on the contrary, they had merely endeavoured to maintain in their original strictness and purity her constitutional principles both theological and ecclesiastical. The other party took a totally different view of the question, and insisted that the oath, being administered by members of the established church, must necessarily be taken in the sense in which it was understood by them; namely, as including all the corruption and inconsistencies that attached to that establishment, and as consequently incompatible with Seceding principles and the solemn testimony they had raised against her errors and backsliding. This dispute, which commenced at the meeting of the Synod in 1745, continued to be maintained with increasing acrimony for two years, or till 1747. The party that were in favour of the oath were called *Burghers;* the party that opposed it were termed *Antiburghers.* In vain did the Burghers offer to agree to a declaration discharging Seceders from swearing the oath as inexpedient under existing circumstances. The Antiburghers peremptorily refused any compromise, and insisted on an act being passed by the Synod declaring it sinful for a Seceder to adopt the oath. Nay, to such an extent was the controversy carried, and so violent were the opinions entertained on the side of the Antiburghers, that the ministers of this party had meanwhile made the oath a test of church communion, and had debarred from the Lord's Table such as maintained its lawfulness. At the spring meeting of the Synod in 1746, the party just named succeeded in carrying a vote to the effect that the oath was subversive of Secession principles. The Burghers protested against this decision. But at a meeting of the Synod in the subsequent year, the Antiburghers, being in a minority in a division on the same subject, withdrew in a body; Mr. Mair, one of their number, having previously protested that "hereby the Burghers had forfeited all their synodical powers, and that the whole power of the Synod devolved on himself and his party and such as clave to them." Next day, the Antiburghers held a synod composed exclusively of their own adherents, twenty-two in number, including ministers and elders, constituted themselves into a distinct and separate sect of Christians, and refused all connection or conference with the opposite party, except on the condition that the latter should appear as penitents at their bar. Nay, they libelled and cited them to this effect; but as the one party did not recognize themselves as responsible to the other, nothing resulted from the step; and the two bodies, followed by their respective congregations, constituted themselves into separate and independent churches. (*Brown's Hist. Acc. of the Rise and Progress of the Secession.*)

But, while the Secession was thus divided into two conflicting parties, the Burghers and Antiburghers, they both continued their separation from, and condemnation of, the established church. They adopted, it is true, her standards, namely, the Westminster Confession of Faith, the Catechism, Larger and Shorter, the Directory for Public Worship, and form of Presbyterian government; but they abrogated patronage unconditionally, and vested the choice of a minister exclusively in the members of each separate congregation. Indeed, the chief practical difference that obtained between the church of Scotland and the Seceding bodies consisted in the one cleaving to patronage, and in the other having abolished that system, and introduced popular election in its stead. Besides, though the church has always been governed by kirk sessions, presbyteries, synods, and a general assembly, the Burghers and Antiburghers, owing to the comparative paucity of their numbers, never adopted a general assembly. With them the synod was the supreme court, whose authority was final in all religious and ecclesiastical matters. The Seceders also were stricter Calvinists, and adopted more rigid discipline as to admission to church-membership, and to *sealing ordinances* (baptism and the Lord's Supper), than the church party had perhaps ever done. (*Ib.*)

Both the Burghers and Antiburghers continued each as rapidly to increase after their separation as the Secession had done when it formed one body; and the animosity which had characterized their disjunction gradually subsided. Indeed, by the time that the generation which witnessed this unhappy schism had passed away, all traces of hostility or opposition had disappeared. The burgess oath, too, which had been the cause of their disunion, fell into desuetude or had ceased to be imposed. The views of the two parties being otherwise identical, and both coinciding in their opposition to the established church, it is not to be wondered at that a wish became general among the members of both parties for a re-union. Overtures to that effect were accordingly made by their respective synods; and after having had many conferences and much discussion on the subject, this happy result was, without any compromise on either side, effected in 1820; and the two bodies, now united, assumed the denomination of the *United Associate Synod of the Secession Church.* At that time, the Burgher persuasion comprehended 10 presbyteries, embracing 120 congregations; and the Antiburghers 11 presbyteries, consisting of 141 congregations. Since their union, their conjoint influence and extension have been considerably on the increase; so that at this date (1841) the Associate Synod comprises no fewer than 360 congregations, with an equal number of ministers. They have not hitherto introduced a general assembly; nor do we hear that they intend to do so. But as they form a numerous, so they are a most respectable body of Christians; and their clergy are eminent not more for professional assiduity than for learning and talents. They are hostile to the establishment of a national church, and are in favour of what is now denominated voluntaryism. They nominate professors of divinity within their own body for the instruction of young men intended for the ministry; but these young men pursue their philosophical and literary studies at any of the Scottish Universities. Their curriculum of study, like that of the established church, extends to eight years. (*M'Culloch's Stat. Acc. of the British Empire*, vol. ii. pp. 425—7.)

BURGH MOTE. (Borough meeting.) A Saxon term for the borough court. *Bergh mote* is the title of a court of miners, held in Derbyshire.

BU'RGLARY. (Lat. burgi latrocinium, *robbery committed in a burg or fenced place.*) In Law, is the breaking and entering the dwelling-house of another in the night time, with intent to commit a felony. If the goods were actually stolen, it is usual to add a count for larceny in an indictment for burglary. This offence is punishable by transportation or imprisonment.

BU'RGOMASTER. (Germ. burgermeister, *chief of the citizens.*) The usual title of the chief municipal officer in German and Dutch towns. In the German free cities, the president of the executive council is styled burgermeister; but in many towns of importance, the title stadt-director (town-governor) has been recently substituted in its stead.

BURLE'SQUE. (Ital. burlare, *to jest.*) The Italian poesia burlesca signifies merely comic or sportive poetry;

but the term, in French and English, is more commonly restricted to compositions of which the humour consists in a ludicrous mixture of things high and low: as high thoughts clothed in low expressions; or, vice versâ, ordinary or base topics invested in the artificial dignity of poetic diction. The humour of parody or travestie (*see* PARODY) arises from the burlesque. *Burletta*, a slight comic musical drama, is derived from the same origin.

BU′RNET. A British plant, whose leaves have been used as a food for sheep. It grows on poor calcareous soils, where few other plants will succeed; and in this its principal value consists, together with its being perennial and remaining green all the winter. It is the *Poterium sanguisorba* of botanists.

BURNING GLASSES and BURNING MIRRORS. The name given to glasses or mirrors so formed as to collect the sun's rays which fall on them into a point or small surface, and thereby produce an intense heat, and set fire to combustible substances. The point at which the rays meet, and where the greatest heat is produced, is called the *focus* or *burning point*. The rays of light or heat may be concentrated either by refraction or reflection: in the former case they must pass through a transparent refracting substance, as glass formed into a proper shape; in the latter they fall on a concave polished surface of silvered glass or bright metal. Reflectors made of glass are usually termed mirrors, those of metal *speculæ*.

In preparing a burning glass, the first thing to be considered is the figure necessary to collect all the rays into the smallest possible space. Descartes, in his *Optics*, showed that a disk of glass, convex on the one side and concave on the other, the convex side being a portion of an elliptic surface, and the concave a portion of a sphere, would cause parallel rays falling on its convex side to converge in a single point; but the practical difficulties of forming a glass accurately into this shape are insuperable: both sides are therefore ground into portions of a sphere. In a refracting mirror the focal length depends on the curvature, or the radius of the sphere, and the refractive power of the substance of which the lens is formed; the focal length in a double convex lens of glass is exactly equal to the radius of curvature. The true form of the reflecting mirror is parabolic, and this form is frequently attempted in metal, which can be cast or hammered nearly into the proper shape; but, as in the case of the refractor, it is the spherical form only which is attempted in glass. The focal distance is equal to the radius of the concavity at the centre of the mirror.

Although the forms given by theory could be obtained in practice with mathematical precision, the solar rays could not even then be collected into a single point; the focus would still have a sensible magnitude. The reason of this is, that the rays which fall on the lens or mirror are not all parallel. Those which come from different parts of the sun's disk are very sensibly convergent, forming an angle of 32 minutes of a degree, equal to the apparent diameter of the sun. Hence the focal image must be of such a magnitude that lines drawn from its opposite edges to the centre of the lens or mirror must form an angle of 32′. Supposing, therefore, the glass or mirror to have a proper form, the space covered by the focus will be proportional only to the focal distance, and entirely independent of the magnitude of the lens or mirror. Hence it follows, that if a portion of the exterior edge of the lens or mirror were covered, the magnitude of the focal image would remain unaltered. The figure of the image is also always circular, independently of the shape of the lens; for example, if one half of the lens were covered, the image would be round as before, though the intensity of the light would then be reduced to one half.

In preparing telescopes or microscopes, where distinctness of vision is the most essential object, it is indispensable that the figure of the lens or mirror be perfectly true. In burning glasses perfect accuracy of figure is not so much required: it is only necessary that the rays be concentrated, the confusion of the image being of no consequence. The effect, however, depending on the number of rays that are brought within the limits of the focus, will necessarily be diminished by the aberration as well as imperfection of figure. When the lens is accurately constructed, and all the rays fall within the focus, the heating power of the solar rays is increased in the proportion of the square of the diameter of the lens to the square of the diameter of the focus. But it is found that, supposing the concentration the same, a much greater effect is produced by a focus of considerable magnitude than a very small one. A glass, for instance, of two inches diameter, with a concentrating power of 300, will produce a much feebler effect than another six inches diameter of the same power; the latter will inflame paper in two or three seconds, while the former will hardly inflame it at all. The reason is that when the heat is concentrated in a very small space it is rapidly dispersed into the surrounding mass; as the focus is increased the accumulation increases in a greater ratio than the dispersion, and the temperature rises. Hence a body in a mass of charcoal, or other substance of very slow conducting power, is fused much more readily than when exposed on all sides to the atmosphere, or imbedded in metal.

The method of exciting heat or producing fire by the concentration of the sun's rays was known from remote antiquity; but the most famous recorded achievement of this kind is that of Archimedes, who is reported to have burned by means of mirrors the Roman fleet in the harbour of Syracuse. Considerable doubts have prevailed respecting the truth of the relation, chiefly grounded on the circumstance that although the setting fire to the fleet is positively affirmed by Dion, Diodorus Siculus, Pappus, and others, no mention is made of it by Livy, Polybius, or Plutarch, who are otherwise minute in detailing the mechanical contrivances of Archimedes, and who were not likely to pass over so notable an occurrence without notice. Descartes went so far, indeed, as to treat the whole relation as fabulous, affirming the thing to be impracticable. Its practicability was, however, experimentally demonstrated by the celebrated Buffon, who, by a combination of plane reflecting mirrors, produced results which must be regarded as of still greater difficulty. With 168 mirrors, each about 6 inches square, he set fire to planks of beech 150 feet distance, and with the faint rays of the sun at Paris in the month of March. It is not necessary to suppose that Archimedes could not place his apparatus within that distance of the fleet of Marcellus; besides, by multiplying the number of glasses, the concentration of the rays may be increased almost to any extent. All this, however, does not prove the actual fact related of Archimedes. Buffon, with all the resources afforded by the advanced state of the arts in the middle of the 18th century, and after a number of experiments, succeeded, with considerable difficulty, in constructing an apparatus by means of which he could inflame combustible substances at a considerable distance. The low state of the arts in the time of Archimedes must have rendered the undertaking considerably more difficult. The silence of those historians who have detailed his other mechanical contrivances can hardly be accounted for, supposing the relation to be true. It seems, therefore, that though something of the kind was contemplated, and to a certain extent practised, the effect has been much exaggerated.

Among those who have amused themselves, in modern times, with the effects of burning glasses or mirrors, are reckoned Baron Napier, the illustrious inventor of the logarithms, Kircher, Dr. James Gregory, Sir Isaac Newton, and numerous others. The most powerful solid lens ever constructed was the work of Mr. Parker, an ingenious London artist. It was made of flint glass, was 3 feet in diameter, 3¼ inches thick at the centre, its focal distance 6 feet 8 inches, the diameter of the burning focus 1 inch, and its weight 212 pounds. The rays refracted by this lens were received on a second, the diameter of which in the frame was 13 inches, and its focal length 29 inches. The diameter of the focus of the combined lenses was half an inch; consequently, by the addition of the second lens, the burning power was increased four times. With this lens some of the most refractory substances were fused in a very short space of time: for example, 10 grs. of common slate in 2 seconds; 10 grs. of cast iron in 3 sec.; 10 grs. of lava in 7 sec.; 10 grs. of jasper in 25 seconds, &c. This glass was afterwards carried to China by one of the officers who accompanied Lord Macartney, and left at Pekin. (For detailed information on this subject, the reader may consult the article BURNING GLASSES in the *Ency. Brit.* 7th edition.)

BU′RSARS. (Lat. bursa.) Originally clerks or treasurers in convents: in more modern times, persons enabled to prosecute their studies at a university by means of funds derived from endowments. It is a singular circumstance that the latter acceptation of this term originated among the Poles, who, even in the 14th century, were accustomed to supply young men of talent with the means of travelling to Germany, and there studying philosophy under the guidance of the monks. This practice was soon adopted by other nations; and, there is now perhaps, no civilised country in which it does not exist, under the name of bursaries, fellowships, exhibitions, scholarships, &c. These endowments are of two kinds: either furnishing the student with the means of prosecuting his studies during the academical curriculum; or enabling him to devote himself, without distraction, to literary pursuits even after the expiration of this period. The Scottish and the Continental universities have adopted the former method; but at Oxford and Cambridge both kinds prevail. The following statistical observations on this subject, in reference to the principal universities of England and Ireland, are extracted from a paper compiled by the Rev. H. L. Jones, M. A., from the most authentic private as well as public documents, and read at Newcastle in August 1838, before the British Association for the Advancement of Science: — In Oxford

there are 24 heads of colleges with a revenue of 18,350*l.*; 557 fellows with 116,560*l.*; 393 scholarships with 6,030*l.*; 199 college officers with 15,650*l.*; 885 benefices and incumbents with 136,500*l.* The revenues of Cambridge, containing 17 colleges, are for an equal number of heads 12,650*l.*; 431 fellows, whose revenue is 90,330*l.*; 793 scholarships with 13,390*l.*; 179 college officers with 17,750*l.*; 252 prizes of the value of 1,038*l.*; 591 benefices and incumbents with 93,300*l.* In Dublin the head of Trinity College receives 2,000*l.*; 25 fellows, 25,400*l.*; 70 scholars, 2,100*l.*; 10 college officers, 20,000*l.*; 62 benefices and incumbents, 9,300*l.* These honours, however, are not open to general competition, being restricted in most cases, by the will of the testator, to natives of certain countries, or to the alumni of particular schools.

At Edinburgh University there are but few bursaries. George Heriot's Hospital (the most wealthy institution in Edinburgh) grants ten bursaries of 20*l.* per annum each, for four years, to individuals not connected with the hospital, who, after a comparative trial before a committee of the governors of the institution, are found duly qualified. There are, besides, a few bursaries of 7*l.* and 10*l.* each, given by the city of Edinburgh to students in the first year of their academical course; two of 10*l.* each to students named Stewart in the second year, and one of 100*l.* to a student selected from those called M'Pherson in the fourth year. To these may be added two ancient bursaries instituted for the benefit of Poles resident in Scotland, which, after lying dormant upwards of a century, were discovered and brought to light in 1837. At St. Andrews, there are several bursaries in the gift of the university; and at Aberdeen, besides the interest of 7000*l.* devoted to the maintenance of certain students at that university, there are a few valuable exhibitions to Cambridge. At Glasgow the most important endowments of this kind are a few exhibitions to Oxford; and those left by Dr. Williamson for Englishmen not connected with the established church. In France and Italy there are no bursaries allowed for the maintenance of students; but any individual, on the payment of a trifling sum, may frequent all the lecture rooms of the professors, who of course are maintained by government.

But it is in Germany that the system of bursaries is in full vigour. There every faculty in the different universities, every public academy, every cloister (for cloisters are still maintained even in the Protestant parts of Germany, though not for the education of priests), every noble family of importance, have bursaries, or, as they are called, Freytische (free tables), at their disposal. These vary in value from 10*l.* to 40*l.* a year, and cease at the expiration of the literary curriculum. As the different bodies or individuals in whom the presentation to these emoluments is vested may select the beneficiary at pleasure, little regard is paid to the real merit or the necessitous condition of the latter.

Whether endowments tend to the promotion of science and learning, is a question that is often discussed, but has not hitherto been solved. Those who maintain that endowments are prejudicial found their arguments on the well-known axiom of Smith, — that in no employment ought the competition to be increased beyond what it naturally demands. Now, as endowments allure into the learned professions, and particularly into the church, a host of individuals who would otherwise have adopted a different occupation, the unavoidable consequence is that the market is glutted, and the supply becomes greater than the demand. Besides, there are and ever will be sufficient numbers to work of their own accord in the accumulation of learning, and this spontaneous industry will be sufficient to keep up an adequate supply to be distributed throughout the country; for supply always equals demand, and demand is always commensurate with the real wants of the people. On the other hand, the advocates of endowments, while they admit the correctness of the above-mentioned axiom as a general rule, maintain that there are many exceptions. In every scientific occupation, they allege, the profits should be proportioned to the time and the labour bestowed in its prosecution. Now, from abstruse studies, such as the higher branches of mathematics, metaphysics, and classical literature, no adequate remuneration results; so that none but the wealthy can pursue these studies, and a reference to history will prove that this class has not been the foremost in classical or scientific attainment. Hence external encouragement is necessary at once to compensate for that want of remuneration to which such studies are exposed, and to divert into this channel a mass of applicable talent which would otherwise be turned to pursuits of more immediate profit and attraction.

BU'RSCHE. (Germ.) A youth, especially a student at a university.

BU'RSCHENSCHAFT. A league or secret association of students, formed in 1815, for the purpose, as was asserted, of the political regeneration of Germany, and suppressed, at least in name, by the exertions of the governments.

BURSCHEN COMMENT. The code of laws adopted by the students for the regulation of their demeanour amongst themselves, &c.

BURSERA'CEA. A natural order of fragrant trees and shrubs inhabiting the tropical parts of the world. They all are resinous and fragrant, although related botanically to Rhamnaceous plants which have no such properties. Indian frankincense, olibanum, colophon, the balsams of Acouchi, Gilead, and Mican, gum elim, and other similar substances, are obtained from plants of this order; besides oil, pitch, and turpentine, resembling the vegetable secretions bearing those names in Europe. They all have alternate unequally pinnate dotless leaves, and racemes or panicles of small green flowers. Their fruit is usually a drupe.

BURTHEN, or BURDEN, OF A SHIP. The weight of merchandise, &c. she is intended to carry. *See* TONNAGE.

BU'SHEL. An English measure of capacity, containing 8 gallons. By act of parliament, 5 George 4. c. 74., the Imperial gallon is declared the standard measure of capacity, and is directed to be made such as to contain 10 lbs. avoirdupois of distilled water, weighed in air at the temperature of 62° of Fahrenheit's thermometer, the barometer standing at 30 inches; or to contain 277 cubic inches and 274 thousandth parts of a cubic inch. Consequently the Imperial bushel contains 80 lbs. of distilled water, or 2218·192 cubic inches.

By the same act the bushel is declared the standard measure of capacity for *coals, culm, lime, fish, potatoes*, or *fruit*, and all other goods or things commonly sold by heaped measure, and is prescribed to contain 2815 cubic inches; the goods to be heaped up in the form of a cone to a height above the rim of the measure of at least three fourths of its depth.

The Winchester bushel, used in this country from the time of Henry VII. to 1826, contained 2150.42 cubic inches. The Imperial bushel is therefore to the Winchester bushel as 2218·192 to 2150·42, or as 1 to ·969447. Hence to convert Winchester bushels into Imperial, multiply by ·969447. *See* MEASURES.

BU'SHMEN. (Dutch, Bosjesmannen, *men of the wood.*) A name given by the Dutch colonists to some roaming tribes akin to the Hottentots, in the vicinity of the Cape of Good Hope. The description given by Governor Janssens of this people is very interesting. So deep are they sunk in barbarism as to be unacquainted even with the construction of huts or tents: "the burning sky being their canopy, and the scorching sand their bed." They are of a dark copper complexion, small in stature, and of a singularly malicious, wild, and intractable disposition.

BUSI'RIS. In Egyptian Mythology, a fabulous personage, of whose origin, exploits, and character Apollodorus, Herodotus, Diodorus Siculus, and other ancient writers have given a most discrepant account. His history is so intimately blended with that of Osiris, that we must refer the reader to that article for further particulars.

BU'SKIN. (Probably bootikin, or *little boot.*) A species of covering for the leg, or rather for the ancle and foot: generally used by English writers as a translation of cothurnus, caliga, and various other Greek and Latin words denoting different kinds of boots, &c. Hence *buskin*, in the sense of *cothurnus*, stands for the tragic drama, that species of dress having been worn in antiquity by tragic actors, in contradistinction to *soccus*, the boot or sock worn by comedians, and used for the comic drama.

> Great Fletcher never treads in *buskins* here,
> Nor greater Jonson dares in *socks* appear.
>
> DRYDEN.

BUST or BUSTO. (It. busto.) In Painting and Sculpture, the head, breast, and shoulders of the human figure.

BU'STARD. *See* OTIS.

BU'TTER. (Gr. βουτυρον, from βους, *a cow*, and τυρος, *cheese* or *coagulum.*) The oily part of milk: 100 parts of cream contain about 4·5 of butter and 3·5 curd; they are separated by the process of churning, during which the butter aggregates. Butter soon becomes sour and rancid, unless purified by melting and straining it so as to separate adhering curd; it is generally preserved by the addition of salt. Its *elain* or oily part has been called *butyrine.* When converted into soap it is said, in addition to the usual products, to afford three odorous volatile compounds, which have been termed by Chevreul the *butyric, capric*, and *caproic acids.*

BU'TTERFLY. The common English name of an extensive group of insects, as they appear in their last and fully developed state, when they constitute the most beautiful and elegant examples of their class. These insects belong to the order *Lepidoptera*, and to the section *Diurna* of Latreille, or the genus *Papilio* of Linnæus. (See those words.)

The changes of an animal form produced by the progressive expansion of the inclosed organs of the body,

and the successive shedding of the outer case or skin, are in no instances so striking or so extraordinary as in the present group of insects. These changes or metamorphoses, as they are commonly but incorrectly termed, have been a favourite theme to the divine and the poet, and a most attractive subject of research to the naturalist. The transition of the humble grub to the gorgeous imago is the subject of the following beautiful passage in the classical work (the *Introduction to Entomology*) of Kirby and Spence: — "Were a naturalist to announce to the world the discovery of an animal which for the first two years of its life existed in the form of a serpent; which then, penetrating into the earth, and weaving a shroud of pure silk of the finest texture, contracted itself within this covering into a body without external mouth or limbs, and resembling more than any thing else an Egyptian mummy; and which, lastly, after remaining in this state, without food and without motion, for three years longer, should at the end of that period burst its silken cerements, struggle through its earthy covering, and start into day a winged bird, — what, think you, would be the sensation excited by this piece of intelligence?" The subterraneous locality of the insect in its passive state, and the silken shroud, are, indeed, less applicable to the butterflies than to other insects; but the circumstances attending the transformations of these beautiful objects are not less remarkable than those of the beetles and moths.

The eggs of the butterfly are deposited on such plants as afford the nutriment most appropriate to the caterpillars that are to be excluded from them; thus the common white butterfly (*Pieris brassicæ*, Latr.) and other species oviposit upon cabbages, and hence have been termed *Brassicariæ:* the gaudy peacock-butterfly lays her eggs upon the nettle. The eggs are coated with a glutinous secretion as they are excluded from the parent, and thus provided with the means of adhesion to the leaves or stems of the plants selected.

The larvæ are long and cylindrical, and consist of thirteen segments, including the head; they have eight feet, and nine spiracles on each side. Those feet which are attached in pairs to the first three segments of the trunk inclose the parts which are developed into the permanent legs of the future butterfly; the remaining five pairs of feet are membranous, short and thick, and are finally lost with the moultings of the skin, whence they are called "pro-legs" by Kirby. The sides of the head are studded with twelve simple globular eyes, extremely minute, and very unlike the single large compound eye of the perfect insect. The mouth is provided with an apparatus characteristic of the mandibulate class of insects, having a pair of large and strong horny jaws working in a horizontal plane, and representing the "mandibulæ;" beneath these a pair of smaller and softer jaws or "maxillæ," and a fleshy lower lip or "labrum" united to the latter, and which is perforated by the outlets of the ducts of the complicated apparatus for secreting the silk. Such a condition of the "instrumenta cibaria" or mechanism of the mouth is in perfect harmony with the habits of the caterpillar, and with the part assigned to this larva or masked Lepidopterous insect in the great theatre of nature. It is there destined to crop and devour the solid succulent parts of the otherwise too luxuriant vegetation, and must have aws amd teeth to perform its task. In its subsequent and final character the butterfly luxuriates on the exquisitely elaborated juices of the flower, and has the power to raise itself above the dull earth, and to transport itself through aërial space.

> Where he arriving round about doth fly
> From bed to bed, from one to other border;
> And takes survey, with curious busy eye,
> Of every flower and herb there set in order.
> Now this, now that, he tasteth tenderly,
> Yet none of them he rudely does disorder;
> Ne with his feet their silken leaves deface,
> But pastures on the pleasure of each space.
>
> SPENSER.

But to exchange a solid for a fluid diet, the instruments of mastication must be converted into those of suction, and the mandibulate insect be transformed into the haustellate one. This is effected by an excessive elongation of the maxillæ, which are grooved each on that side which is turned towards its fellow; and, by the union of their opposed margins, these grooves are converted into a capillary canal, by which the nectar is pumped up into the mouth. When not in action, this siphon is coiled up in a series of spiral turns, and is protected by the other parts of the mouth, which retain their rudimental condition. The nymphs are almost always naked, and of an angular form; they are generally suspended by the tail, and reflect more or less of a golden lustre, whence they are termed *chrysalides* and *aureliæ*. Reaumur has given the best account of the singular operations by which the butterflies attach their aurelian cases to the points of suspension, and afterwards extricate themselves from these cases when their transformation is completed.

Some butterflies have all their six feet in the imago state well developed, and alike in both sexes; and the chrysalis, in addition to the ordinary terminal or posterior attachment, is looped up in a horizontal position by a silken band or sling passing round the body. The internal margin of the hinder lower pair of wings is concave or folded, and the tarsal hooks or spurs are well developed. These are the butterflies proper, the *Papiliones equites* of Linnæus. Those "knights" which bear red spots on the chest are the "Trojans" of Linnæus, and those without red spots on the chest bear the name of the Grecian heroes. Some of these butterfly-knights have the anterior pair of feet remarkably shorter than the others; and this arrest of development would seem to be compensated by greater powers of flight. The butterflies of the section thus characterized, or the *Nymphalidæ*, are also remarkable for the brilliancy of their colouring. Numerous other sections and subdivisions have been founded by modern entomologists upon characters afforded by modifications of the antennæ, palpi, and other parts. In the "Plebeian" butterflies of Linnæus the larvæ are oval, the chrysalides short, and the tarsal spurs of the imago are extremely small.

BU'TTER TREE. A remarkable plant found by Park in the interior of Africa, especially in Bambarra, yielding from its kernels, by pressure, a white, firm, rich butter, which, even in that climate, will keep well for a year without salt. Another species is the Phulwara tree of India (*Bassia butyracca*), whose seeds produce a firm, agreeable, buttery substance, of about the consistence and colour of hog's lard; it is used medicinally in rheumatic affections. The Illupie tree of Coromandel (*Bassia longifolia*), and the Madhuca tree of Bengal (*Bassia latifolia*), are other species having similar properties. They are large tropical trees, belonging to the natural order *Sapotaceæ*, and their timber is sometimes of excellent quality.

BU'TTERS, MINERAL. A name given by the old chemists to some of the *chlorides* on account of their soft butyraceous texture when recently prepared; such as *butter of antimony, of arsenic*, and *of bismuth.*

BU'TTERS, VEGETABLE. The concrete fixed oils, such as those of the cocoa and chocolate nuts, of the nutmeg, &c., which are solid at common temperatures, are often distinguished by the above term.

BU'TTON. The round mass of metal collected at the bottom of a crucible after fusion, or which remains in the cupel in the process of assaying, is called by this name.

BU'TTRESS. (Fr. aboutir, *to lie out.*) In Architecture, a mass of brickwork or masonry, built to resist the horizontal thrust of another mass. Buttresses are much used in Gothic architecture, to resist the thrust of the vaulting which covers the naves and aisles of cathedrals. When open they are called flying buttresses.

BUTTS. Short ridges of different lengths, which necessarily occur in the angle of a field when the direction of the ridges is not parallel to one of the sides.

BU'ZZARD. *See* FALCO.

BY'ARD. A piece of leather crossing the breast, used by the men who drag the sledges in coal mines.

BY-LAWS, or BYE-LAWS. (The first syllable from the Danish By, *town* or *hamlet.*) Orders and constitutions of corporations, courts-leet and courts-baron, commoners, or inhabitants of vills, &c., of which the effect is to impose obligations not enforced by common or statute law. The validity of by-laws rests on the authority of the parties making them, established either by immemorial custom, or by their corporate character; for the power of making by-laws is inherent in a corporation. But the superior courts of law have the power of annulling a by-law, if it be unreasonable, or in restraint of trade, or imposing a charge without any apparent benefit to the party, &c. By the Municipal Corporations Amendment Act (5 & 6 W. 4. c. 76. s. 90.) by-laws are to be made by the town council of the borough, and to be valid unless disallowed by the king in council within forty days.

BYRE. A word used in Scotland for a cow house.

BY'RRHUS. A Linnæan genus of minute Clavicorn Coleopterous insects, now the type of a family, including those pests of museums which feed in the larva state on bird-skins, preserved insects, &c. The genera in this family are *Byrrhus* proper, *Simplocaria, Oomorphus, Syncalapta, Nosodendron, Aspidiphorus, Trinodes*, and *Anthrenus*. Of the latter genus there are six British species, of which the *Anthrenus musæorum* may be regarded as the type.

BY'SSIFERS, *Byssifera.* (Lat. Byssus, and fero, *I carry.*) A family of Lamellibranchiate Acephalous Mollusks, comprehending those species which are attached to foreign bodies by means of a byssus.

BY'SSOLITE. (Gr. βυσσος, *flax*, and λιθος, *a stone.*) A soft fibrous mineral from the Alps.

BY'SSUS. (Gr. βυσσος, *fine flax.*) A fasciculus of shining semitransparent horny or silky filaments, secreted by a gland at the base of the foot in certain Lamellibranchiate Bivalves, and serving as an organ of adhesion to submarine rocks or other foreign bodies.

BYSSUS. A name formerly given to all those filamentous plants which inhabit cellars and other under-

ground close places, and on which no fructification is found; it was also applied to vegetation of a similar kind when found growing in the air. It is now certain that a large number of these supposed plants are merely the young state of certain kinds of fungi, or other plants of a low organization; and, although a few species are still retained in the genus, as *Byssus floccosa*, and others, it is by no means certain that they are really of a different nature.

BYZA'NTINE HISTORIANS. A series of Greek historians and authors, who lived under the Eastern Empire between the 6th and the 15th centuries. They may be divided into three classes: 1. Historians whose works form a continuous history of the Byzantine Empire from the fourth century of the Christian era down to the Turkish conquest of Constantinople. They are nearly thirty in number, with various shades of literary merit; but their works constitute the almost only authentic source of the history of that eventful period. 2. General chroniclers or historians, whose works, embracing a wider range than those of the former, treat chiefly of the chronography of the world from the oldest times. 3. Authors who confined their attention to the politics, statistics, antiquities, manners, &c. of the Romans. These two classes combined amount also to about thirty, and their writings give an excellent illustration of the times of which they treat, whether as historians, chroniclers, antiquaries, or politicians. The works of the Byzantine historians, &c. were collected and published by order of Louis XIV. in 36 vols. folio, Paris, 1645-1711. Another and more complete edition was published at Venice in 1729 and the following years. Besides these many of the Byzantine historians were published separately at different places. But all that had previously been done to evince the importance of these historians, by the publication of their works, was destined to be eclipsed in our own times. The late professor Niebuhr of Bonn, eminently fitted for the task by his attainments both natural and acquired, projected a new edition of the Byzantine Historians (*Corpus Scriptorum Historiæ Byzantinæ. Editio emendatior et Copiosior*, 8vo. Bonnæ, 1828), which he superintended till his death. Upwards of 34 volumes have already appeared; and the editorial management of the work is entrusted to Becker, Dindorf, and other distinguished philologists.

C.

C, the third letter of the English and most other European alphabets, is borrowed immediately from the Latin alphabet, in which it first appears; but is derived originally from the *κ* or *γ* of the Greeks. In English it is pronounced like *s* before *e* and *i*, and like *k* before *a*, *o*, *u*, and may consequently be considered as superfluous in the alphabet. According to orthographers there are few letters so susceptible of interchanges as this letter, and much ingenuity has been expended in exhibiting its convertibility. As an abbreviation, C is used in ancient MSS. for Caius, Cæsar, Consul, Civitas, &c.; and as a numeral for a hundred. It was the symbol of condemnation in the Roman tribunals (being abbreviated for *Condemno*); and was consequently termed *litera tristis*, in contradistinction to A (used for *Absolvo*), symbolical of acquittal, and thence called *litera salutaris*.

C. In Music, the name of one of the notes in the scale. It is a character also used for the signification of the time. *See* Music.

CAA'BA. The famous square stone in the temple of Mecca, the object of the adoration of the entire Mohammedan world. According to the tradition of the Arabs, it is the first spot on earth which was consecrated to the worship of the Deity, having been presented by the angel Gabriel to the patriarch Abraham on the occasion of the building of the temple. As is well known, Mohammed enjoined all his followers to visit the shrine of Mecca once in their lifetime; and to preserve continually on their minds a sense of their obligation to perform this duty, he directed that in all the multiplied acts of devotion which his religion prescribes, true believers should always turn their faces towards this holy place, called Kebla. It may be added, that the eastern authors frequently designate the temple in which the square stone is concealed, with all its appendages, as Caaba.

CABA'L. (Fr.) In History, was applied originally to the five cabinet ministers of Charles II.—Clifford, Ashley, Buckingham, Arlington, and Lauderdale — whose initials happened to form the word; and it has since been used for a junto of individuals, who, too insignificant in point of numbers to form a party, endeavour to effect their purposes by underhand measures.

CA'BALA. A Hebrew word signifying the oral tradition which the Rabbins conceive to complete the system of scriptural interpretation. They maintain that it was delivered in the first instance to Adam, and again to Abraham and Moses, by direct revelation; but that since the time of Esdras the memories of the priests and elders have sufficed to preserve it in all its purity. As the Masora details the literal explanation of the language of scripture, so the Cabala reveals the hidden truths of which it is the symbol. Every sentence, word, and letter of the inspired volume contain, according to these interpreters, a figurative as well as a direct sense. The former is also not uncommonly manifold; and a word may be interpreted according to the arithmetical power of the letters which compose it, which species of cabala is called *gematria*; or according to the meaning of each individual letter, the entire word thus constituting a sentence, which is called *notaricon*; or finally according to certain transpositions of the letters, which is denoted by the term *themurah*. What the mysterious doctrines of the cabala which were thus discovered actually were, is not very clearly ascertained; but the system seems to have been an invention of the philosophising Jews of the latter centuries preceding our era, with the view of accommodating the speculations of the Gnostics to the religion of the Old Testament.

The Christian cabalists in later times practised a kind of magic under this name, pretending to the power of divination by certain combinations of scriptural characters.

CABA'LLUS. In Mythology. *See* Pegasus.

CABIA'I. In Zoology, the name under which the Capibara or water-hog (*Hydrochorus capibara*, Erxl.) is described by Buffon. *See* Capibara.

CA'BINET. In Politics, the governing council of a country: from the cabinet or apartment in which the ruler transacts public business and assembles his privy council. In England a few of the ministers only are *ex officio* members of the cabinet. The ministers who are raised to this honour are styled by way of eminence Cabinet ministers, and are more immediately responsible for the acts of the sovereign, as well as for public measures. The distinction between the king's cabinet ministers and the rest of his privy council seems not to have been established in public usage in England before the reign of William III.

CAB'IRI. In Pagan Mythology, sacred priests or deified heroes, venerated by the Phœnicians originally as the founders of religion. Various opinions have been entertained concerning the nature and origin of the Cabiri; but from the multiplicity of names applied to them, together with the profound secrecy observed in the celebration of their rites, an almost impenetrable veil of mystery has been thrown around their history. They seem to have been men who, having communicated the art of melting metals, &c., were deified by a grateful posterity. Their worship was chiefly cultivated in the island of Samothracia, whence it was afterwards transferred to Lemnos, Imbros, and certain towns of Troas. (*Strabo*, x. 473.) They were styled the offspring of Vulcan, though their name was derived from their mother Cabera, daughter of Proteus. Their number is variously given. Those who were initiated in their rites were held to be secured against all danger by sea and land. Their distinguishing badge was a purple girdle. An ingenious account of the Cabiri has been given by Professor Müller of Göttingen, in a dissertation appended to his work on Orchomenus, wherein he rejects the Phœnician or oriental origin of the Cabiri, and regards their worship as purely Pelasgic, and down to a certain point the principal religion of the Greeks.

CA'BLE. (Gr. *καπλιον*, *a rope.*) The rope or chain by which the anchor of a ship is held. Cables in Europe, until within a recent period, were usually made of hemp, but of late years iron chains have come much into use. A hempen cable of 12 inches girth, and length 120 fathoms, weighs 3075 lbs. Since the weights of two cables of equal lengths will be as their sections, or squares of the girths, it is easy to deduce the following rule for the weight of any hempen cable: — Multiply the square of the girth in inches by 21·3 (or 21 nearly enough), the product is the weight in lbs. Since also as the breaking strain, or resistance against the force to part the cable, will be as the section, it will be as the weight, and will be found nearly by dividing the weight in lbs. by 100; the quotient is the breaking strain in tons. This rule is of course liable to great uncertainty from the quality or wear of the cable. Chain cables possess great advantages over hempen cables; they are not liable to be destroyed by chafing on rocky grounds, nor to become rotten and insecure from alternate exposure to the air and water; and by reason of their greater weight the strain is exerted on the cable rather than on the ship. In order that the ship may be enabled to let slip her cable in case of necessity, chain cables are furnished with bolts at distances from each other of a fathom or two, which can be readily withdrawn. A chain of which the section is 1 inch in diameter breaks with 16 tons; such a chain is equivalent to a 10 inch hemp cable nearly. And the dimensions of the chain cable corresponding to any hemp cable are therefore easily found by merely dividing the circumference of the hemp

cable by 10. The strength of every part of the chain is proved before it leaves the manufactory. The first patent for a chain cable was taken out in 1808 by Mr. Slater, a surgeon in the Royal Navy.

CA'BLED. In Architecture, the filling up the lower part of the flute of a column with a cylindrical piece like a cable.

CABO'MBEÆ. (Cabomba, the name of one of the genera.) In Botany, the name given by Richard to the natural order now called *Hydropeltideæ*.

CA'CHALOT. In Ichthyology, a name for the spermaceti or sperm whale (*Physeter macrocephalus*, Linn.).

CACHE'T, LETTRES DE. In France, under the ancient government, letters signed with the private seal (cachet) of the king. As warrants for the detention of private citizens, they appear to have been rarely employed before the 17th century. In the reign of Louis XIV. their use became frightfully common. But in other respects they had been not unfrequently made use of, even in earlier times, to interfere with the course of justice; as, by way of injunction to a party not to exercise certain authority, or pursue certain legal steps, &c. Lettres de cachet were never so multiplied as under the administration of Cardinal Fleury: not less than 80,000 are said to have been issued, without any legal judgment, in the proceedings against the Jansenists. Fifty-nine are said to have been issued against the family Mirabeau in the reigns of Louis XV. and XVI., of which twenty-two against the famous count himself. So scandalously were they abused, that there is an instance of a countess obtaining one for the imprisonment of her maid, who had repeated some scandal against her! They were abolished Jan. 15. 1790.

CACHE'XIA. (Gr. κακος, *bad*, and ἕξις, *a habit*.) A bad state or habit of body; whence the term *cachexiæ*, or cachectic disorders.

CA'CHOLONG. A milk-white chalcedony, originally found on the borders of the river Cach in Bucharia. Cholong, in the language of the Calmucks, is said to signify a stone.

CACHU'NDE. A celebrated Chinese medicine, composed chiefly of aromatic stimulants.

CA'CODÆ'MON. (Gr. κακοδαίμων, *an evil spirit*.) *See* DÆMON.

CACO'PHONY. (Gr. κακος, *bad*, and φωνη, *a sound*.) In Rhetoric, a defect of style, consisting in a harsh or disagreeable sound produced by the meeting of two or more letters or syllables, or by the too frequent repetition of the same letters or syllables: *e.g.*

And oft the ear the open vowels tire. — POPE.

CACTA'CEÆ. (Cactus, one of the genera.) A small natural order of Exogens, remarkable for their gay and large flowers, and for the grotesque forms of some of the species. They are found wild in hot dry countries, in arid situations, where they are enabled to exist because of the thickness of their skin, which allows very little moisture to be lost through it. Many of the species are like succulent Euphorbias, from which they are however known by their not milking when wounded. All the species are harmless; some have eatable fruit; and one, the *Opuntia cochinillifera*, is the favourite haunt of the cochineal insect.

CA'CUS. In Fabulous History, the son of Vulcan, a robber of Italy, whose dwelling was in the Aventine wood. His exploits form the subject of a fine episode in the 8th book of the *Æneid*. He was represented as a frightful monster of enormous strength, who, after a long life of crime, was at length slain by Hercules, from whom he had stolen some oxen. To express his gratitude for his victory, Hercules erected the *Ara Maxima;* and Evander, with his infant colony of Arcadians, performed divine honours to Hercules as their benefactor.

CA'DDICE-WORMS, or CASE-WORMS. The larvæ or grubs of the Trichopterous insects are so called, on account of being inclosed in a sheath or case. This is always composed of extraneous substances glued together by a cement excreted from the skin of the grub; and different species of the caddis-worm protect themselves by means of different materials thus joined together. Some, which pass their larva state under water and creep along the bottom, combine bits of sticks or rushes with small pebbles or shells, to make their cases heavier than water; others, which float on the top and gather their food from thence, form a slight and slender tube of a narrow slip of grass, which is rolled round the body in a spiral direction, with the edges so nicely fitting as to seem but one piece. In every case the worm adheres by a pair of hooks at its hinder extremity to the bottom of the sheath, and only protrudes the head and two following segments, the skin of which is harder than that covering the rest of the body. Those which creep at the bottom drag themselves along by means of their mandibles. At the conclusion of their existence as grubs, they moor their case to some large stone or other fixed and submerged body, and close the outlet by a net-work of silken threads, which prevents the entry of any inimical intruder, but admits the water necessary for respiration. They then cast their outer skin, and for a while remain in the usual passive condition of a pupa; and now the organizing energy is vigorously effecting the wonderful changes which lead to the full perfection of the insect. But, as it would be obviously dangerous to the air-breathing imago to be excluded in its first feeble state under water, the pupa here exhibits a locomotive power which is without a parallel in other orders of the metamorphotic insects: being provided with a pair of small and sharp hooks at the head, it cuts the threads with which in a previous state it had confined itself, and creeping out of the water casts off its pupa skin, and emerges a May-fly or *Phryganea*.

CA'DENCE. (Ital. cadenza, *a falling*.) In Music, the conclusion of a song, or of some parts thereof, in certain places of the piece, dividing it as it were into so many numbers or periods. The cadence takes place when the parts fall or terminate on a note or chord naturally expected by the ear, just as a period closes the sense in the paragraph of a discourse. A cadence is either perfect or imperfect. The former when it consists of two notes sung after each other, or by degrees conjoined in each of the two parts, the harmony of the fifth preceding that of the key note; and it is called perfect, because it satisfies the ear more than the latter. The latter imperfect; that is, when the key note with its harmony precedes that of the fifth without its added seventh. A cadence is said to be broken or interrupted when the bass rises a major or minor second, instead of falling a fifth.

CADE'T. (Fr.) A pupil in a military academy, whose aim is to qualify himself, by a due course of study, to enter the service of Her Majesty or that of the East India Company as an officer of the line, artillery, or engineers. In this country there are three grand institutions for the education of cadets: Sandhurst for the British line; Woolwich for the artillery and engineers; and Addiscombe for the Indian army, both line and artillery. The academy at Sandhurst was instituted by George III for the purpose of affording general and professional instruction to the sons of private or military gentlemen, with the view of their obtaining commissions in the British army without purchase. Before the commission is conferred, the cadet must undergo an examination before a competent board in the classics, mathematics, military drawing, &c. The expenses of this academy were formerly defrayed by government; but a change was recently introduced, by which the sons of private gentlemen must pay an annual sum of 125*l*., and the sons of general or other officers less sums in proportion to their rank.

The academy at Woolwich was established with the view of qualifying cadets for the artillery or engineers; and to this institution the master-general of the ordnance has the sole right of granting admission. As the nature of the establishment at Woolwich requires the prosecution of a more strict and professional course of study than at Sandhurst, the attention of the cadets is specially directed to geography; general history, ancient and modern; modern languages; military drawing and surveying; mathematics; engineering and fortification. After the lapse of four years, generally, the cadets undergo an examination in the above-mentioned branches of science; when the most distinguished are selected for the engineers, the others for the artillery. And here it may be observed, that not merely the cadet academy, but the whole vast establishment at Woolwich, its arsenal, its repository, its laboratory, are component parts of one and the same great school of military science.

As the college of Addiscombe is established for the education of officers of the line, artillery, and engineers for the Indian army, the plan of instruction pursued there combines the two systems adopted at Sandhurst and at Woolwich. In order to become a cadet in this institution, it is necessary to have the promise of a commission from a director of the East India Company; and after a prescribed examination, an appointment is obtained in one of the branches of the Indian army, according to the merit or pleasure of the cadet. We may here incidentally remark, that no cadet, even after being thoroughly versed in the theory of military science, is suffered to join the engineers either of the Queen's service or that of the E. I. Company, before he has gone through a regular course of practical instruction in sapping, mining, and the whole processes of a siege, as well as in other departments of field engineering, pontooning, the construction of military bridges, &c., in the admirable establishment for these purposes at Chatham. (*United Service Jour.*)

In France the academies for cadets which existed previously to the French Revolution have been merged in the Polytecnic schools.

The Dutch possess two institutions of this nature; one at Breda, the other at Delft.

In the United States there is one on nearly the same principle as that at Addiscombe.

In Germany every small state has a military school:

while those at Berlin, Vienna, and Munich are on so extensive a scale as to challenge a comparison with any similar institutions in Europe. In Germany, too, the word cadet has a wider signification than in this country, being applied to those persons who, without having frequented a military school, join the army in the expectation of obtaining a commission when they have gained a competent knowledge of the service.

In Russia there is a famous academy for cadets, which was instituted by Anna at St. Petersburg in 1732; and since its foundation has afforded instruction in military science to upwards of 9000 pupils, many of whom have acquired celebrity in the annals of Russian literature.

CA'DI. (In Arabic, *a judge.*) Among the Turks the inferior judges are styled Cadi. The Spanish Alcayde or Alcalde is derived from the same root.

CA'DMIUM. A white metal, much like tin; it fuses and volatilizes at a temperature a little below that at which tin melts. Specific gravity about 9. Its ores are associated with those of zinc. It was discovered in 1818 by Professor Stromeyer of Gottingen. Its equivalent number is 56. It forms a yellow salifiable oxide, composed of 56 cadmium + 8 oxygen = 64 oxide of cadmium. Its scarcity prevents its employment in the arts, but the oxide has been used as a pigment.

CADU'CEUS. In Antiquity, a rod of laurel or olive with a representation of two snakes twisted round it. It was the symbol of peace, and formed the chief badge of the Grecian heralds, whose persons were held sacred. In Mythology, the Caduceus was the symbol of Mercury, thence called Caducifer, to whom it was said to have been presented by Apollo in return for his invention of the lyre.

CADU'CIBR'ANCHIATES. (Lat. caducus, *fading;* branchiæ, *gills.*) Those Batrachians which undergo a metamorphosis, and lose their branchial apparatus before arriving at the period of maturity; as the frog, toad, salamander, and newt.

CADU'COUS. (Lat. cado, *I fall.*) In Botany, when a part is temporary, and soon disappears or falls off.

CÆ'CA. (Lat. cæcus, *blind.*) In Comparative Anatomy, the blind processes of the alimentary canal are generally so called. Those in fishes occur at the beginning of the intestines, where they are often numerous and long, representing the pancreas. In birds they are found near the termination of the intestines, and are generally two in number. In mammals the cæcum is commonly single, and situated at the beginning of the large intestines; it is of enormous size in the herbivorous species with simple stomachs. In the lower animals the intestinal glands which communicate with the intestines generally retain their primitive form of cæca.

CÆ'CUM. (Lat. cæcus, *blind.*) In Human Anatomy, the first portion of the large intestines, in which the *ileum* terminates by a valve. The cæcum is a kind of appendage to the intestinal canal, open at one end only, whence the name *blind gut;* it has a small process attached to it, called the *appendix cæci vermiformis.*

CÆ'SAR. This title, originally the name of a branch of the Julian family at Rome, was assumed as a mark of dignity by the emperors after Nero. It became subsequently the title of the presumptive heir to the empire, and the next title of dignity after Augustus; but was superseded in the Greek empire under Alexis Comnenus by that of Sebastocrator. In the West, it was assumed by the emperors of Germany; and, in German "Kaiser," is now the peculiar title of the emperor of Austria, who has succeeded to several of the dignities of the former.

CÆSA'REAN OPERATION. The extraction of the child from the womb by an operation. Julius Cæsar is said to have been thus brought into the world.

CÆSU'RA. (Lat. cædo, *I cut.*) In prosody, a metrical break in the verse, occasioned by the separation of the first syllable of a foot, forming the last of a word, from the next syllable, forming the first of another. In the Latin hexameter the principal cæsura, without which the line is unmusical, occurs generally after the tenth, sometimes not until after the fourteenth time (each long syllable containing two times, each short syllable one: *see* RHYTHM); thus,

Arma virumque cano | Trojæ qui primus ab oris
Speluncæ vivique lacus | at frigida Tempe.

The slight pause which follows the syllable at which the interruption takes place is termed the cæsural pause. In English verse a line is frequently musical without any cæsura at all; *i. e.* in which the pause takes place always at the end of a foot. But a cæsura in the middle of the third, and in the middle of the fourth foot of an heroic verse, are by no means uncommon, and particularly appropriate in blank verse, in which they represent the two common cæsuræ of the Latin hexameter.

I sing the sofa | I who lately sang
Of man's first disobedience | and the fruit.

In the first of these lines the cæsura is in the third, in the latter in the fourth foot.

CAFFE'IN. A bitter crystallizable substance contained in coffee. A portion of it volatilizes during the roasting of coffee. It has not been applied to any use.

CAHIE'R. (Fr.) Derived by some from the Lat. *codex*, by others from *quaternio*. It signifies in its proper sense a number of sheets of paper loosely tied together. In French history, it denotes the reports and proceedings of certain assemblies; as those of the clergy, the states general, the notables, &c. The famous cahiers presented by the states general to the king of France at their convocation on the 24th of June, 1789, contain the best account of the then state of France. They were systematized and condensed in a book in 3 volumes, called "L'Esprit des Cahiers," to which the reader is referred.

CAI'NCIC ACID. A peculiar acid discovered by Pelletier and Caventou in the bark of the cainca root, a Brazilian shrub employed for the cure of intermittent fever.

CAI'NITES. A strange sect of heretics, who appeared about 159, A.D. They probably originated in some of the various schools of Manicheism; and, if their doctrines are truly reported to us, they are said to have asserted that the power which created heaven and earth was the evil principle; that Cain, Esau, Korah, the people of Sodom, and others whom the Old Testament represents as victims of peculiar divine judgments, were in fact children of the good principle, and enemies of the evil. Some of them are said to have published a gospel of Judas on the same principle. The Quintilianists, so called from a lady named Quintilia, of whom Tertullian speaks, were an offset of this sect.

ÇA IRA, ÇA IRA. (Literally, *it* (the Revolution) *shall go on.*) The burden of a famous revolutionary song, which was composed in the year 1790 in denunciation of the French aristocracy. The tune and sentiments of this song were much inferior to those of the Marseillaise Hymn ("Allons enfans de la patrie"), the object of which was to rouse the French to defend their country against foreign aggression.

CAIRN. A word of Celtic origin, used to denote the piles of stones of a conical form so frequently found on the tops of hills, &c. in various districts; erected probably, as Sir R. C. Hoare observes, in general, for the mere purpose of memorials, although some have assigned to them a peculiar character, as receptacles for the bodies of criminals burnt in the wicker images of the Druids, &c. According to some antiquaries, *cairn* is distinct from *carnedd*, the Welsh name for heaps of stones on the tops of high mountains (Carnedd David, Carnedd Llewellyn, &c.), which are said to have been sacrificial. Some cairns are undoubtedly sepulchral. In common language, a cairn is distinguished from a barrow, the former being a heap of stones, the latter a mound of earth; but in all probability they had for the most part the same object, and the difference of materials was merely occasioned by local circumstances. *See* BARROW.

CAIRNGO'RM STONE. A yellow or brown variety of rock crystal or crystallized silica, from the mountain Cairngorm in Scotland.

CA'ISSON. (Fr.) In Architecture, a sunken panel in a flat or vaulted ceiling, or in the soffit of a cornice. In ceilings they are of various geometrical forms, and often enriched with rosettes or other ornaments. *Caisson*, in bridge building, is a large chest or vessel in which the piers of a bridge are built. This sinking as the work advances, its bottom at last comes in contact with the bed of the river, when the sides are disengaged, its construction being such as to admit of their being thus detached without injury to the floor or bottom.

CA'JEPUT OIL. A volatile oil obtained by distilling the leaves of the *Melaleuca minor*, a shrub abundant in Amboyna and Borneo, whence the oil is imported. This oil is of various shades of green, highly pungent and aromatic, and powerfully stimulant and diaphoretic. It has been much extolled as a remedy in the Asiatic cholera, but other essential oils are probably as effectual.

CA'LAMARY. (Calamus, *a pen;* theca calamaria, *the pen-fish.*) A Cephalopod; so called because it has a horny substance shaped like a quill in its back, and contains an ink-bag in its visceral sac: it is the *Loligo vulgaris* of Cuvier.

CA'LAMINE. A native carbonate of zinc, *Lapis calaminaris*. It is a zinc ore used in the manufacture of brass.

CA'LAMUS. (Gr. καλαμος, *a reed.*) A name occasionally employed in botany for such simple fistular stems, without articulations, as occur in rushes and similar plants.

CA'LAMUS AROMA'TICUS. The rhizoma of the *Acorus calamus*, common over the whole of Europe in moist situations; it is usually known under the name of *sweet flag*. An infusion of the root is a good aromatic tonic. It yields a very small portion of essential oil when distilled with water (scarcely exceeding a thousandth part of its weight), which is used by perfumers.

CALA'THIUM, or CALATHIDIUM. (Gr. καλαθος, *a cup.*) Is a botanical term, employed by some German

botanists to denote that kind of depressed contracted inflorescence which is found in composite flowers. It is in reality an umbel with all the flowers sessile.

CALATRA'VA, ORDER OF, IN SPAIN, so denominated from a castle taken from the Moors, was instituted by Sancho III. King of Castile, in 1158. The kings of Spain are perpetual grand masters of this order of knighthood.

CA'LCAR. (Lat. calcar, *a spur.*) This term is applied by botanists to all hollow prolongations downwards of leaves or the parts of a flower. The long hollow horns which hang down from one of the sepals of a Tropœlum, or from the labellum of an Orchis, or the curved bodies enclosed within the hood of an Aconite flower, are described by this name.

CALCA'REOUS SOIL. (Lat. calx, *lime.*) Soil of which lime forms a principal component part. Kirwan alleges that no soil will continue long fertile that does not contain some proportion of lime; and this has been subsequently proved by what takes place in North America. See *Ruffin's Essay on Calcareous Manures.*

CALCEOLA'RIA. (Calceolus, *a small slipper.*) A genus of beautiful herbaceous or shrubby plants with yellow, or orange, or purple flowers, the lower half of which is shaped something like an old-fashioned slipper. They naturally inhabit rocks, rich plains, and woods, in Chili, Peru, or New Grenada. In this country many of them are hardy enough to live in the open air in summer; and some will even endure our winters, if not very severe. They are, however, all cultivated with most success if regarded as greenhouse plants.

CALCINA'TION. The reduction of substances to cinder or ash. The term is derived from the Latin word *calx*, quicklime, which, as is well known, is prepared by the action of heat upon limestone; and hence the old chemists employed the word *calcination* to express any supposed analogous change, metallic substances being apparently converted into earthy matter by calcination.

CA'LCIUM. The metallic base of lime, discovered in 1808 by Davy. This substance has hitherto been obtained in such small quantities, that its properties have not been accurately investigated. It is probably a brilliant white metal, highly inflammable, and more than twice as heavy as water. Combined with oxygen it forms lime, which consists of 20 calcium + 8 oxygen = 28 lime.

CALC-SI'NTER. (German. From kalk, *lime*, and sintern, *to drop.*) The calcareous deposit of certain springs.

CALC-SPAR. Calcareous spar, or crystallized carbonate of lime.

CA'LCULA'TION, CA'LCULUS. (Lat. calculus, *a small pebble*, the Romans having made use of pebbles in casting up accounts.) In modern language, the term *calculus* is employed to denote any branch, or any operation of mathematics, which requires or may involve numerical calculation; and therefore may be applied to the whole of the mathematical sciences, excepting pure geometry. Thus that part of algebra which treats of exponents is called the *experimental calculus.* In like manner the phrases *calculus of definite integrals*, *calculus of functions*, *calculus of variations*, &c., are used to denote certain branches of the higher mathematics. *See* DIFFERENTIAL CALCULUS, INTEGRAL CALCULUS, VARIATIONS.

CA'LCULUS. (Dimin. of calx, *a limestone.*) In Physiology, the general term for inorganic concretions of various kinds, formed in various parts of the body, and bearing in shape or composition a general resemblance to stones. The term *calculus* is, however, generally confined to urinary concretions. *See* URINE.

CALDA'RIUM. (Lat.) In Ancient Architecture, by some authors used in the same sense as Laconicum, was an apartment in the baths heated for the purpose of causing perspiration. Vitruvius, however, used the word to signify a hot bath.

CALEA'NTHUM. Pliny's term for copperas.

CA'LEMBOURG. A French expression for that kind of witticism which in English is denominated a pun. A certain Westphalian Count Calemberg (Kahlenberg), who visited Paris in the reign of Louis XV., and was famous for his blunders in the French language, is said to be the person immortalized by the employment of his name to designate this species of jeu de mots.

CA'LENDAR. A distribution or division of time into periods adapted to the purposes of civil life; also a table or register of such divisions, exhibiting the order in which the seasons, months, festivals, and holidays succeed each other during the year. The word is derived from the ancient Latin verb *calare*, to call. In the early ages of Rome, it was the custom for the pontiffs to call the people together on the first day of each month, to apprise them of the days that were to be kept sacred in the course of it. Hence *dies calendæ*, the calends or first days of the different months.

The calendars in use throughout Europe are borrowed from that of the Romans. Romulus is supposed to have first undertaken to divide the year in such a manner that certain epochs should return periodically after a revolution of the sun; but the knowledge of astronomy was not then sufficiently advanced to allow this to be done with much precision. He placed the commencement of the year in spring, and divided it into 10 months — March, April, May, June, Quintilis, Sextilis, September, October, November, and December. March, May, Quintilis, and October contained thirty-one days each; the other six contained only thirty. The names Quintilis and Sextilis remained in the calendar till the end of the republic, when they were changed into July and August; the former in flattery of Julius Cæsar, and the latter of Augustus.

The year of Romulus contained only 304 days. Numa added two months; January to the beginning of the year, and February to the end. About the year 452 B. C. this arrangement was changed by the Decemvirs, who placed February after January; since that time the order of the months has remained undisturbed. In Numa's year the months consisted of 29 and 30 days alternately, to correspond with the synodic revolution of the moon. The year would therefore consist of 354 days; but one day was added to make the number odd, as being more lucky. In order to produce a correspondence with the solar year, Numa ordered an intercalary month to be inserted every second year between the 23rd and 24th of February, consisting alternately of 22 and 23 days. Had this regulation been strictly adhered to, the mean length of the year would have been 365¼ days, and the months would have continued for a long time to correspond with the same seasons. But a discretionary power over the intercalary month was exercised by the pontiffs, who frequently abused it for the purpose of hastening or retarding the days of the election of magistrates; and the Roman calendar continued in a state of uncertainty and confusion till the time of Julius Cæsar, when the civil equinox differed from the astronomical by three months.

Under the advice of the astronomer Sosigenes, Cæsar abolished the lunar year, and regulated the civil year entirely by the sun. He decreed that the common year should consist of 365 days; but that every fourth year should contain 366. In distributing the days among the different months, he ordered that the odd months, that is, the first, third, fifth, seventh, ninth, and eleventh, should contain each 31 days, and the other months 30; excepting February, which in common years was to contain only 29 days, but every fourth year 30 days. This natural and convenient arrangement was interrupted to gratify the frivolous vanity of Augustus, by giving August, the month named after him, an equal number of days with July, which was named after the first Cæsar. The intercalary day, which occurred every fourth year, was inserted between the 24th and 25th of February. According to the peculiar and awkward manner of reckoning adopted by the Romans, the 24th of February was called the sixth before the calends of March, *sexto calendas.* In the intercalary year this day was repeated, and called *bis-sexto calendas;* whence the term *bissextile.* The corresponding English term, *leap year*, appears less correct, as it seems to imply that a day was *leapt* over instead of being thrust in. It may be remarked, that in the ecclesiastical calendar the intercalary day is still inserted between the 24th and 25th of February.

The Julian year consisted of 365¼ days, and consequently differed in excess by 11 minutes 10·35 sec. from the true solar year, which consists of 365 d. 5 h. 48 m. 49·62 sec. In consequence of this difference the astronomical equinox, in the course of a few centuries, sensibly fell back towards the beginning of the year. In the time of Julius Cæsar it corresponded to the 25th of March; in the sixteenth century it had retrograded to the 11th. The correction of this error was one of the purposes sought to be obtained by the reformation of the calendar effected by Pope Gregory XIII. in 1582. By suppressing 10 days in the calendar, Gregory restored the equinox to the 21st of March, the day on which it fell at the time of the Council of Nice in 325; the place of Easter and the other moveable church feasts in the ecclesiastical calendar having been prescribed at that council. And in order that the same inconvenience might be prevented in future, he ordered the intercalation which took place every fourth year to be omitted in years ending centuries; that is to say, on the 100th, 200th, &c.; excepting on the 400th, and the years which are multiples of 400. The Gregorian rule of intercalation may therefore be expressed as follows: —

"Every year of which the number is divisible by 4 without a remainder is a leap year, excepting the centesimal years, which are only leap years when divisible by 4 after suppressing the two zeros." Thus 1600 was a leap year; 1700 and 1800 were common years; 1900 will be a common year, 2000 a leap year, and so on.

The Gregorian method of intercalation thus gives 97 intercalations in 400 years; consequently 400 years contain $400 \times 365 + 97 = 146097$ days, and therefore the length of one year is 365·2425 days, or 365 d. 5 h. 49m. 12 sec., which exceeds the true solar year by 22·38 sec., an error which amounts only to one day in 3866 years.

If an astronomer were required, without any reference to established usages, to give a rule of intercalation by which the commencement of the civil year, while it always coincided with the commencement of a day, should deviate the least possible from the same instant of the solar year, he would proceed as follows:—The length of the mean solar year being 365·242241 days, the excess above a whole number of days is ·242241, which converted into a continued fraction becomes

$$\cfrac{1}{4+\cfrac{1}{7+\cfrac{1}{1+\cfrac{1}{4+\cfrac{1}{7+\cfrac{1}{1+,\ \&c.}}}}}}$$

Whence the following series of approximative fractions is derived.

$$\frac{1}{4},\quad \frac{7}{29},\quad \frac{8}{33},\quad \frac{39}{161},\quad \frac{281}{1160},\quad \frac{320}{1321},\ \&c.$$

Of these the first gives an intercalation of 1 day in 4 years, which supposes the year to be 365¼ days. The second gives 7 intercalations in 29 years, and supposes the length of the year to be 365 d. 5 h. 47 m. 35 sec., which is somewhat too small. The third fraction, $\frac{8}{33}$, is remarkable, as giving a year which differs in excess from the true solar by 15·38 seconds; so that by intercalating 8 times in 33 years, or 7 times successively at the end of every fourth year, and once at the end of the fifth year, the difference between the civil and solar year would only accumulate to a day in about 5600 years, while in the Gregorian calendar the error amounts to a day in 3860 years. Nevertheless the Gregorian rule has this advantage, that leap year is always readily distinguished.

The Gregorian calendar was received immediately or shortly after its promulgation by all the Roman Catholic countries of Europe. The Protestant states of Germany, and the kingdom of Denmark, adhered to the Julian calendar till 1700; and in England the alteration was successfully opposed by popular prejudices till 1752. In that year the Julian calendar, or *old style*, as it was called, was formally abolished by act of parliament, and the date used in all public transactions rendered coincident with that followed in other European countries, by enacting that the day following the 2nd of September of the year 1752 should be called the 14th of that month. When the alteration was made by Gregory it was only necessary to drop 10 days; the year 1700 having intervened, which was a common year in the Gregorian but a leap year in the Julian calendar, it was now necessary to drop 11 days. The old style is still adhered to in Russia and the countries following the communion of the Greek church; the difference of date in the present century amounts to twelve days.

Ecclesiastical Calendar.—The adaptation of the civil to the solar year is attended with no difficulty; but the church calendar for regulating the moveable feasts imposes conditions less easily satisfied. The early Christians borrowed a portion of their ritual from the Jews. The Jewish year was luni-solar; that is to say, depended on the moon as well as on the sun. Easter, the principal Christian festival, in imitation of the Jewish passover, was celebrated about the time of the full moon. Differences of opinion, and consequently disputations, soon arose as to the proper day on which the celebration should be held. In order to put an end to an unseemly contention, the Council of Nice laid down a specific rule, and ordered that Easter should always be celebrated on the Sunday which immediately follows the full moon that happens upon, or next after, the day of the vernal equinox. In order to determine Easter according to this rule for any particular year, it is necessary to reconcile three periods; namely, the week, the lunar month, and the solar year. To find the day of the week on which any given day of the year falls, it is necessary to know on what day of the week the year began. In the Julian calendar this was easily found by means of a short period or cycle of 28 years (*see* Cycle), after which the year begins with the same day of the week. In the Gregorian calendar this order is interrupted by the omission of the intercalation in the last year of the century. But to render any calculation unnecessary a table is given in the prayer books, showing the correspondence of the days of the year and the week for the current century. (*See* also Dominical Letter.) The connection of the lunar month with the solar year is an ancient problem, for the resolution of which the Greeks invented cycles or periods, which remained in use with some modifications till the time of the Gregorian reformation. (*See* Metonic Cycle, Golden Number.) The author of the Gregorian calendar, Luigi Lillo Ghiraldi, or, as he is frequently called, Aloysius Lilius, employed for the same purpose a set of numbers called Epacts (for an explanation of the use of which *see* Epact). It is to be desired that this complicated system of rules and tables were rendered unnecessary by abolishing the use of the lunar month, and causing Easter to fall invariably on the same Sunday of a calendar month; for example, on the first or second Sunday of April.

New French Calendar.—A new reform of the calendar was attempted to be introduced in France during the period of the Revolution. The commencement of the year was fixed at the autumnal equinox, which nearly coincided with the epoch of the foundation of the republic. The names of the ancient months were abolished, and others substituted having reference to agricultural labours, or the state of nature in the different seasons of the year. But the alteration was found to be inconvenient and impracticable, and after a few years was formally abandoned. (Cycle, Era, Hejira, Year.)

CA'LENDER. A machine for pressing and smoothing cloth and other articles, which when so prepared are said to be *calendered*. It literally means *hot-pressing;* from *calor*, heat.

CA'LENDS, in the ancient Roman calendar, were the first days of each month. The Roman month was divided into three periods by the *Calends*, the *Nones*, and the *Ides*. The *Calends* were invariably placed at the beginning of the month; the *Ides* at the middle of the month, on the 13th or 15th; and the *Nones* (*novem*, nine) were the ninth day before the Ides, counting inclusively. From these three terms the days were counted backwards, in the following manner:—Those days comprised between the calends and the nones were denominated *days before the nones;* those between the nones and the ides, *days before the ides;* and those from the ides to the end of the month, *days before the calends*. Hence the phrases *pridie calendas, tertio calendas*, &c.; meaning the second day before the calends, or last day of the month, the third day before the calends, or last but one of the month (the *calends* or first day of the following month being included in the reckoning), and so on. In the months of March, May, July, and October, the ides fell on the 15th day, and the nones, consequently, on the 7th. In all the other months the ides fell on the 13th, and the nones, consequently, on the 7th. The number of days receiving their denomination from the calends depended on the number of days in the month and the day on which the ides fell. For example, if the month had thirty-one days, and the ides fell on the 13th (as happened in January, August, nd December), there would remain eighteen days after the ides, which, added to the first of the following month, made nineteen days of calends. Hence the 14th day of January was styled the *nineteenth before the calends* of February; the following day, or 15th of the month, was *the eighteenth before the calends*, and so on.

CALE'NDULIN. A mucilaginous substance or species of gum obtained from the *marigold*.

CA'LENTURE. (Lat. caleo.) A delirious fever, produced by the sun, in which it is common for the patient to imagine the sea to be green fields.

CA'LIBER, or CALIPER. (Fr. calibre.) The thickness or diameter of any round or cylindrical body, as of the bore of a gun or of its ball.

CA'LICO-PRINTING. The art of producing figured patterns upon calico; they are transferred to its surface by blocks, copper plates, or engraved cylinders, by which the colours are directly printed, or by which *mordants* are so applied that when the calico is immersed in a colouring bath, the colour only adheres or is produced upon the parts to which the mordant had been previously applied. *See* Dyeing.

CA'LIDUCT. (Lat. calidus, *hot*, and ductus, *a conveyance*.) In Architecture, a pipe or flue for the distribution of heat in an apartment or house.

CALIGI'DÆ. A family of parasitic Entomostracous Crustaceans, belonging to the order *Siphonostoma*, characterized by having the mouth organized for piercing and suction. The parasites of this family prey almost exclusively upon fish, and are commonly called fish-lice. Gold-fish are sometimes infested to an almost incredible extent with a species, the *Monoculus foliaceus* of Linnæus, which is nearly a quarter of an inch long, having the body covered with a broad round transparent shield, notched behind to give free motion to the tail. The first pair of legs are shaped like a cupping-glass, and for the purpose of holding on; the four last pairs are formed for swimming, and terminated each by two long and feathered filaments, probably subservient to respiration.

CA'LIPER COMPASSES, or simply Calipers, are compasses with curved legs, for measuring the caliber or diameter of cylinders, balls, or other round bodies. Calipers of the best sort are made with a scale having different sets of numbers engraved on it, like a sliding rule, for the purpose of exhibiting at once various relations depending on the magnitude of the diameter of the body measured. Thus, as the weights of balls of the same metal are in a constant ratio to the cubes of their diameters

the scale may be so graduated and numbered that the observer may read off either the diameter in inches, or the weight in pounds. Other numbers having a less immediate application are also frequently attached: for example, the degrees of a circle, the proportions of troy and avoirdupois weight, tables of the specific gravities and weights of bodies, &c. It is obvious that these may be varied infinitely, according to the purposes proposed to be accomplished. This word is probably derived from the Greek καλλειπω, *I leave behind*.

CA'LIPH. (Arab. khalifah.) Originally a deputy or lieutenant, but afterwards applied chiefly to the successors or representatives of Mohammed, who exercised the highest spiritual and temporal jurisdiction over the "Faithful." At first there was little difficulty in determining the right of succession to the caliphat, as it devolved on the immediate descendants or relations of the prophet: but in the course of time violent disputes arose upon this point among several Mohammedan dynasties, and led to the establishment of the caliphats of Africa (Fatimide), and of Spain (Omayzade), which were contemporary with that of the Abassides of Bagdad. The splendour of the empire founded by Mohammed reached its highest pitch towards the beginning of the ninth century, under the famous Haroun al Raschid. The period of its decline may be dated from the commencement of the tenth century; and for the last 200 years the appellation of caliph has been swallowed up in *Shah*, *Sultan*, *Emir*, and other titles peculiar to the east.

CALI'PPIC PERIOD. In Ancient Chronology, is a correction of the Metônic cycle proposed by Calippus. The Metonic cycle was a period of nineteen solar years, at the end of which time the new moons return again on the same days of the year. The period contained exactly 6940 days. Now 6940 days exceeds 235 lunations by only seven hours and a half. At the end of four cycles, or 76 years, the accumulated excess of 7½ hours amounts to one whole day and six hours. Calippus therefore proposed to quadruple the period of Meton, and to deduct a day at the end of it by changing one of the months of 30 days into a month of 29 days. (*See* METONIC CYCLE.) The period of Calippus is sometimes referred to as a date by Ptolemy.

CALI'XTINES. One division of the Bohemian Reformers, who in the 15th century protested against the errors of the church of Rome, and maintained their independence by force of arms. After the death of Huss, his followers split into two principal parties, under the names of Taborites and Calixtines; of which the latter were the most moderate, and held out chiefly on the ground of the refusal of the cup (calix) to the laity, whence they derived their name. Their hostility was at length propitiated by indulgence on this point: the church of Rome declaring expressly at the same time that the giving or withholding of the sacramental wine is a matter of ecclesiastical ordinance merely, and neither the one nor the other essential to the reception of the benefits of the eucharist. The council of Basle (1431) says,— Sive sub unâ specie sive duplici quis communicat, secundum ordinationem seu observationem ecclesiæ, proficit dignè communicantibus ad salutem.

The same name is given to the followers of Calixtus, a German divine of the 17th century, who proposed a reconciliation between the Roman Catholics, Lutherans, and Reformed church, on the basis of the Apostles' Creed.

CALLI'GRAPHY. (Gr. κάλλος, *beauty*, and γράφω, *I write*.) The art of beautiful writing. The scribes who made a profession of copying manuscripts, before the invention of printing, have been termed Calligraphers. Their art consisted not merely in writing, but also in embellishing their work with ornamental devices, although illumination (which see) was also practised as a distinct employment. Among the MSS. of the early part of the middle ages which we possess, there are some sumptuous specimens of the art, written in letters of gold, vermilion, &c. and on leaves of different colours, but that fashion went early out of use; and in general it may be said, that the current writing of calligraphers diminished in beauty and in laborious minuteness, especially in Italy, during the centuries immediately preceding the invention of printing.

CALLIO'NYMUS. (Gr. καλλος, *beauty*, and ονομα, *a name*.) A genus of beautiful spiny-finned fishes, with very small gill openings; ventral fins under the throat, and larger than the pectorals; head oblong, flattened; eyes placed near to each other, and directed upwards; no teeth on the palate; intermaxillaries capable of considerable protrusion. They have no air bladder. The gemmeous, or golden dragonet (*Callionymus lyra*), is a British example of this genus.

CALLI'OPE. (Gr. καλλος, *beauty*, and οψ, *the voice*.) In Mythology, one of the Muses usually associated with Homer in the statues of antiquity, and thence considered as the patroness of heroic poetry.

CALLI'TRICHA'CEÆ. (Callitriche, the only genus.) A small cluster of imperfectly organized water plants, the natural relation of which is unsettled. By some they are considered allies of *Urticaceæ*, by others of *Naiadaceæ*, and others Monocotyledons.

CALLORHY'NCHUS. *See* CHIMÆRA.

CA'LLUS. In Osteology, the matter which unites the divided ends of broken bones: it is a secretion of new bony matter.

CA'LOMEL. The old chemical name of *chloride of mercury*. The word is perhaps derived from καλος, *fair*, and μελας, *black*. It is prepared by rubbing mercury with corrosive sublimate, which forms a *black* mixture, which, by the application of heat, yields a *white* sublimate of calomel. It is much used in medicine, especially as a purgative. It consists of 200 mercury + 36 chlorine = 236 chloride of mercury or calomel.

CALO'RIC. (Lat. caleo, *I am warm*.) A term applied by the French chemists to designate *the matter of heat*, it being assumed that the phenomena of heat are dependent upon the presence of a highly attenuated, mobile, and imponderable form of matter. *See* HEAT.

CALORI'FIC RAYS. A term applied to the invisible heating rays which emanate from the sun, and from burning and heated bodies.

CALOR'IMETER. (Lat. calor, *heat*, and metrum, *a measure*.) An instrument for measuring the quantity of heat given out by bodies in passing from one temperature to another.

CALORIMO'TOR. (Lat. calor, *heat*, and moveo, *I put in motion*.) This term has occasionally been applied to a peculiar form of the voltaic apparatus composed of one pair of plates of great extent of surface, the electricity of which, when transmitted through good conductors, produces intense heat.

CA'LOSO'MA. (Gr. καλος, *beautiful*; σωμα, *body*.) A genus of most splendid Coleopterous insects, belonging to the family *Carabidæ*, or ground beetles. In this genus the jaws are toothless, or rather devoid of notches; the maxillary palpes terminate in a large joint, and the abdomen is broad. There are two British species: *Calosoma sycophanta*, so called because its grub insinuates itself into the nests of gregarious caterpillars, and feeds upon them; and *Calosoma inquisitor*. In speculating on the exception which the Calosomes present among the *Carabidæ*, in the brilliant colours which are developed in them, an explanation seems to be afforded by a difference in their habits: they frequent trees, and are more exposed to the light than their hole-and-corner congeners, the ground-beetles.

CA'LOYERS. Monks of the Greek church, who follow the rule of St. Basil.

CALP. An argillo-ferruginous limestone.

CALU'MBA. The root of the *Cocculus palmatus*. It is dried in slices of a yellowish grey colour, and is generally worm-eaten. It has a bitter and slightly pungent taste, and is very mucilaginous. Calumba root is an excellent tonic medicine, especially in debility of stomach and intestines: about ten grains of the powder may be taken twice or thrice a day. The Mozambique name of this plant is Kalumba.

CA'LUMET. (Lat. calamus, *a reed*.) In Modern History, a large beautifully adorned pipe, used by the North American Indians as the emblem of peace. (*Harris's Voyages*, vol. ii. p. 908.) The first notice of the calumet among European writers is to be found in Ferdinand de Soto's account of his expedition through the southern provinces in 1470.

CA'LVINISTS. The followers of Calvin, the second great reformer of the 16th century, and founder of the church of Geneva. The distinguishing tenets of this celebrated theologian refer to points both of discipline and doctrine. He was the first to reject the episcopal form of church government, originally, it is said, with great reluctance, and compelled thereto by the want of regularly ordained ministers; but he afterwards maintained the exclusive divine appointment of the Presbyterian system, which has since obtained favour in Scotland, and among the Protestants of France, and has had numerous adherents in this country and America. The doctrinal opinions of Calvin, however, have not been permanently received among those who have adopted his views respecting the ministry. On the contrary, in England and Geneva, there are many Presbyterians Arminian in sentiment. It was at the Synod of Dort, in 1618, that the points in dispute between the Calvinists and Arminians were most accurately distinguished, and arranged under five heads, upon which the former party asserted the following opinions:—

1. Of predestination—that all men have sinned in Adam, and are become liable to the curse; but that God has by an eternal decree chosen some from the beginning, to whom he should impart faith of his free grace, and consequently salvation.

2. Of the death of Christ—that it is a sufficient sacrifice for the sins of the whole world; and that some only believe and are saved, whereas many perish in unbelief, arises not from any defect in this sacrifice, but from the perversity of the non-elect.

3. Of man's corruption—that all men are conceived

in sin and born the children of wrath, and are neither willing nor able to return to God without the aid of the Holy Spirit.

4. Of grace and free will—that the influence of the Spirit upon our fallen natures does not force, but only quickens and corrects them, inducing them gently to turn themselves towards God by an exercise of their free will.

5. Of perseverance—that God does not wholly take away his Spirit from his own children, even in lamentable falls; nor does he permit them to fall finally from the grace of adoption and the state of justification.

These opinions, which were laid down at the Synod of Dort, represent the sentiments of the founder of this school, and of the ancient or *strict* Calvinists. In modern times another class of *Moderate Calvinists* has arisen, who differ from these in holding lower notions concerning reprobation and the extent of Christ's sacrifice. For other subdivisions among the Calvinists, see articles SUB-LAPSARIANS and SUPRA-LAPSARIANS.

CALX. A name applied by the alchemists to all products of combustion, especially those obtained from the metals, which were supposed to be converted into a species of *earth*.

CALY'BIO. (Gr. καλυβη, *a cottage.*) A name adopted by some carpologists, for such a one-celled, inferior, one or few-seeded fruit, enclosed in a cupule, as the acorn of the oak, the mast of beech, &c.

CA'LYCANTHA'CEÆ. (Calycanthus, one of the genera.) A small natural order of plants related to *Rosaceæ*. They are all shrubs with fragrant flowers, and inhabit North America or Japan. Some of them resemble the genus *Illicium* in their flowers.

CA'LYCERA'CEÆ. (Calycera, one of the genera.) A natural order of plants related to *Compositæ*, from which they differ very little, excepting that their seeds are pendulous and albuminous, and their anthers half united. The species are woody herbaceous plants, inhabiting the warmer parts of South America.

CALY'CULUS. A diminutive of *Calyx*, which see.

CALY'MENE. (Gr. κεκαλυμμενη, *concealed.*) A name devised to express the obscure nature of a genus of Trilobites (fossil crustaceans), to which it is attached, and which is distinguished from all other Trilobites by the faculty which the species possesses of rolling the body up into the form of a ball, in the same manner as the recent genera *Sphæroma, Armadillo, Glomeris;* viz. by approximating the two extremes of the trunk at the under part. The anterior segment or shield of Calymene is as broad or broader than it is long, and supports two compound prominent eyes; the posterior or terminal segment forms a sort of triangular elongated tail.

CALY'PSO. (Gr.) In Fabulous History, a daughter of Atlas, according to Homer, but of Oceanus and Thetys, according to Hesiod, was the queen of the island Ogygia. On this island Ulysses suffered shipwreck; and Calypso, by the united influence of her love and spells, prevailed on him to remain and share her sceptre. After the lapse of seven years, however, his desire to revisit his native country became irrepressible, and he resolved to forego his honours in Ogygia. Calypso tried every expedient, offering him even the bribe of immortality, to induce him to remain; but all her efforts proved unavailing, and on his departure she died of grief. The island of Ogygia, placed by Pliny (iii. 10.) off the Lacinian promontory, between the Tarentine and Scyllian bays, has long since been engulfed in the ocean, along with the famous islands of the Sirens.

CALYPTRÆ'A. (Gr. καλυπτρα, *a covering.*) The name of a genus of Gastropods, having a patelliform shell, to the concavity of which adheres either a smaller conical shell, like a cup in a saucer, or a semicircular testaceous process, forming the commencement of a columella. The branchiæ consist of a single row of long and slender filaments. The foot is circular, expanded, and furnished with two anterior processes. The genus, originally established by Lamarck, is now divided into the subgenera *Calypeopsis, Crepipatella*, and *Calyptræa*.

CA'LYX. (Gr. καλυξ, *a cup.*) The name given by botanists to the outermost of the enveloping organs of a flower. It is usually green, and sometimes bears a great resemblance to leaves; but it is also frequently richly coloured, as in the *Mirabilis, Salvia splendens*, &c. This organ appears to have the office of protecting the more tender parts lying within it, and is therefore usually present in flowers; when absent, its protecting office is always performed by some modification of bracts, as in the Arum and the Willow. If it is adherent to the sides of the ovary, it is called superior; if partially adherent, half superior; and if quite free from the sides of the ovary, it is inferior. In systematical botany these differences are of great importance.

CAMARI'LLA. (Span.) The *little* or private chamber of the sovereign of Spain (equivalent to the *petits appartements* of the old French regime); but the term is generally applied to his immediate confidants, who are usually all-powerful in the government of the country. In England the term is nearly synonymous with *clique*.

CA'MBER. (Fr. cambrer, *to bend.*) In Architecture, the convexity of the upper and concavity of the under side of a beam, by which it is prevented from becoming straight or concave at top either by its own weight, or by the loading it may have to carry.

CA'MBIUM. (A low Latin word for liquid which becomes glutinous.) A viscid secretion formed between the liber and alburnum of Exogenous trees in the early spring, when vegetation recommences. It is supposed by some physiologists to be the matter out of which new wood and bark are formed; by others to be a preparation of organizable matter, out of which the horizontal growth of the cellular system, and the vertical growth of the woody system, may be nourished during their respective development. It disappears as soon as the new wood and bark have been completely formed.

CA'MBRIC. A delicate linen fabric, which was originally manufactured at *Cambray*.

CA'MEL. A machine invented by the Dutch for carrying vessels into harbours where there is not a sufficient depth of water. It consisted of two large boxes, or half ships, built in such a manner that they could be applied on each side of the hull of a large vessel. On the deck of each part of the camel a number of horizontal windlasses were placed, from which ropes proceeded, on one side, and being carried under the keel of the vessel, were attached to the windlasses on the deck of the other part. When about to be used as much water as necessary was suffered to run into them; all the ropes were then cast loose, and large beams were placed horizontally through the port-holes of the vessel, the ends resting on the camels alongside. When the ropes were made fast, and the vessel properly secured, the water was pumped out, on which the camels rose and bore up the vessel. (*Beckman's History of Inventions*, vol. iii. p. 337.)

CAME'LEON or CHAMÆLION MINERAL. Manganesate of potash, obtained by melting a mixture of potash and black oxide of manganese. When put into water the solution is first green, and passes through a variety of tints of green, purple, and red, till at length it becomes colourless.

CAME'LIDÆ. (Camelus, *a camel.*) A family of ruminant Mammalia, which deviates from the rest of the order in the presence of two incisors in the upper jaw, and the absence of cotyledons in the uterus and fœtal membranes. The camel and dromedary of the old world, and the llama, guanacho, and vicugna of the new world, are the existing species of this family.

The old world Camelidæ (*Camelus*) are especially organized for existence in the arid and barren deserts of Asia and Africa. They have a broad, expanded, elastic foot, terminated in front by two comparatively small hoofs, and well defended beneath by a felt of coarse hair. The new world Camelidæ (*Auchenia*) have narrower feet, and the hoofs are bent in the form of claws, adapted to climb the steep passes of the mountain ranges of South America, to which continent they are confined.

Besides the peculiar characters above mentioned, the camels present a modification in the structure of the stomach which is not present in any other family of Ruminantia. There are developed from the sides of the first cavity of the stomach or paunch two series of cells, into which experiment has proved that the water which the animal drinks almost exclusively passes, and where it can be kept apart from the solid contents of the paunch in a quantity of several quarts. Surely the final relation of such a modification of structure to the peculiar physical characteristic of the localities to which the animal possessing it is confined must force itself irresistibly on the mind. But besides a reservoir of water to meet the exigencies of long journeys across the desert, the dromedary and camel are provided with a storehouse of solid nutriment on which they can draw for supplies long after every digestible part has been extracted from the contents of the stomach: this storehouse consists of one or two large collections of fat stored up in ligamentous cells supported by the spines of the dorsal vertebræ, and forming what are called the humps. When the camel is in a region of fertility the hump becomes plump and expanded; but after a protracted journey in the wilderness it becomes shrivelled and reduced to its ligamentous constituent, in consequence of the absorption of the fat. Buffon carried his teleological reasoning, or the ascription of design, so far as to assert that the humps on the backs of the camel were badges of slavery, and intended to adapt them to the burthens of their task-masters; and he supported this ingenious idea by the unfounded assertion that the dorsal prominences did not belong to the camels in free nature. But the true uses of the fatty humps, as of the water-cells, relate to the exigencies of the Camelidæ of the deserts under every condition. The complete adaptation of the camel for the dreary wastes in which it is destined to exist, is further illustrated by some minor modifications in its structure. The nostrils are narrow oblique slits, defended with hair at their margins, and provided with a sphincter muscle, like the eyelids; so that the animal can close them at pleasure. This action

is of great service in excluding the fine and penetrating sand which is drifted along in clouds by the storms of the desert. The expanded sole of the foot, elastic as a cushion, prevents the leg from sinking in the loose surface: the long joints and lofty tread of the camel are equally adapted for a rapid progression along loose sandy plains. Thus to the Arab of the scorching desert the camel is as valuable, and indeed as essential, as the reindeer to the Laplander in his region of perpetual snow. The one animal, like the other, serves, while living, for all the purposes of draught and burden, and supplies his master's family with milk. When dead the flesh of the camel is eaten, though it is coarser than that of the ordinary Ruminants: its hide, which approaches that of the Pachyderms in thickness and strength, is applied to the manufacture of saddles, harness, pitchers, shields, and various other articles. The finer hair is manufactured into articles of clothing, and the coarser hair is woven into a kind of matting for the covering of tents. By day the camels transport their owner and his family, with all their property, from place to place. By night the body of the recumbent beast of burden serves as a pillow for his master; or if the air be agitated, the camels are arranged to windward, so as to form a barrier against the ever-shifting sands.

The camel is the sole medium of communication between those countries which, are separated by extensive deserts; in the beautiful and expressive metaphor of eastern speech, it is "the ship of the desert," and in truth it is the only ship by which the wilderness can be navigated with certainty and safety. A stout Arabian camel can travel with a load of 800 pounds at the rate of about three miles in the hour. The swifter varieties, as the light dromedary or "mahairy," are said to carry a single rider over a space of from 70 to 100 miles in 24 hours, and that for several days in succession.

CAME'LLIA. (In honour of Kamel, a Spanish Jesuit.) A beautiful genus of evergreen shrubs inhabiting China and Japan. Several species are known; one of which, *C. oleifera*, furnishes the Chinese with abundance of oil used for various domestic purposes; others are small-flowered and unimportant; but one, *C. japonica*, is among the most beautiful species in the vegetable kingdom. It is from this that the multitudes of double varieties, now common ornaments of gardens in the spring, have been obtained by sowing seeds. Most of the varieties originated with the Chinese and Japanese; but many very fine ones have been raised in this country and Belgium. They are usually cultivated in pots, but are never seen in perfection unless planted in the open ground beneath a glass roof: under such circumstances they only require to be guarded from severe frost by some kind of heating apparatus. In some parts of England, and even near London, they are occasionally grown in the open air, but with little success.

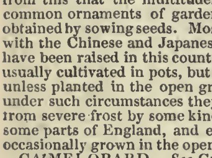
CA'MELOPARD. *See* GIRAFFE.

CAME'LOPARDA'LIS. One of the constellations formed by Hevelius in the northern hemisphere. It is situated between Cepheus, Cassiopeia, Perseus, Ursa Major, Ursa Minor, and Draco.

CA'MEO. A word of doubtful origin, applied to gems of various colours sculptured in relief. The art of engraving on gems boasts of high antiquity, having been practised with various degrees of success by the Egyptians, Greeks, and Romans. It was again revived in Italy in the 15th century, and is even at the present day cultivated with great avidity and considerable success. The cameos of the ancients were usually confined to the agate, onyx, and sard, which, on account of the variety of their strata, were better accommodated to a display of the artist's talents; but they are also occasionally found executed on opal, beryl, or emerald, and even on a sort of factitious stone, the *Vitrum obsidianum* of Pliny, distinguished by the moderns as the antique paste. (*Encyc. Metr.*) One of the most famous cameos is the onyx at present in Paris, called the *apotheosis of Augustus*. It is one foot in height and ten inches in width.

CA'MERA LU'CIDA. The name given by Dr. Hooke to an instrument contrived by him for making the image of any object appear on a wall in a light room either by day or by night. It is described in the *Phil. Trans.* vol. xxxviii. p. 741.

The instrument now known by the name of Camera Lucida is a very ingenious invention of the late Dr. Wollaston, for the purpose of enabling any one, without a knowledge of the rules of drawing or perspective, to delineate distant objects, or trace the outlines of landscapes &c., with perfect accuracy. It consists of a quadrangular glass prism, *a*, *b*, *c*, *d*, by means of which rays of light are bent, by two reflections, into a path at right angles to their previous direction. A ray of light proceeding from O enters the face of the prism at *a*, and continues its course in a straight line till it meets



the adjacent side of the prism at *b*, and making with it a very acute angle, is wholly reflected in the direction *b c*. At *c* it again meets the side of the prism, and is in like manner reflected in the direction *c* E. The eye being placed at E, sees the image of the object on the surface of the prism at *c*, and refers it to P, on a plane M N, which may be covered with a sheet of white paper. The point of a pencil can also be seen on the paper, and thus the accurate outline of the object may be traced. It is easy to see from this the proper form which the crystal should have. Suppose the two reflections to be equal, then the ray will be bent 45° from its original path by the first, and also 45° by the second; and the four angles which it makes with the faces of the prism at *b* and *c* are each 22½°; hence the faces *a* and *d* being perpendicular, the faces *a* and *b* must be inclined in an angle equal to three fourths of a right angle, or 67½°; *b* and *c* must make an angle of 135°, or three fourths of two right angles; and *c* and *d* make an angle of 67½°. By the laws of optics, the size of the picture will bear the same relation to the object delineated, that the distance of the eye from the paper bears to the distance of the object. Hence, in order to increase or diminish the size of the picture, the prism is mounted in a brass frame, supported by brass tubes capable of being lengthened or shortened at pleasure. A thin brass plate, affixed to the upper surface of the prism, and having a small hole in it for the observer to look through, keeps the eye in its proper place, and procures steadiness of vision. A convex lens may be placed over the hole in the brass plate, for the purpose of magnifying the image; or a concave lens placed before the prism at *a* will adapt it to short-sighted persons. The instrument is extremely convenient, on account of its portability.

The construction of the camera lucida may be varied in several ways. The following was proposed by professor Amici. A parallel piece of

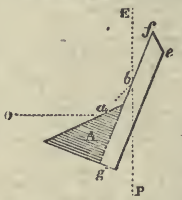


plate glass, *e f g*, is connected with a reflecting speculum A. The ray of light proceeding from O is reflected from the speculum at *a* to the plate glass at *b*, and there reflected again to the eye at E. The frame in which the instrument is placed has a rectangular opening at the top, through which the eye receives the image, and is prevented from receiving the rays coming directly from the metallic mirror. The image is referred to a plane below at P, where the pencil is seen through the glass.

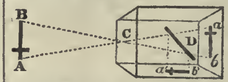
CA'MERA OBSCU'RA, or DARK CHAMBER, is an optical apparatus, by which the images of external objects are thrown on a white surface, and represented in a vivid manner in their proper colours, shapes, &c. Hence the apparatus may be used for the purposes of delineation, as well as the camera lucida; but as it is from its construction less convenient, it is chiefly used as a source of amusement, or for explaining the nature of vision.

The theory of the Camera Obscura is shortly this.



Through a convex lens, or small circular hole at C, the light is admitted into a darkened room or box, so that rays proceeding from an object A B, and falling on a white ground within the room, paint an image of the object on it in an inverted position, *a b*. But the image is easily restored to its natural position by causing the rays to pass through two convex lenses inserted in a draw tube placed in the opening C. Sometimes a mirror D is placed in the interior of the box, making an angle of 45° with its sides, whereby the image is thrown down on the bottom of the box at *a b*, and by means of the reflection restored to its natural position. The best ground for receiving the image is plaster of Paris, formed somewhat concave. The image is viewed through an oblong aperture cut in the box. The most perfect camera obscura is formed by placing an inclined mirror in a revolving frame at the top of a building, by which the rays are thrown down on a convex lens in the roof, and the images of all the surrounding objects received on a table. The images being accompanied by the motions belonging to the objects, a very pleasing picture is formed. The invention of the camera obscura is usually ascribed to Baptista Porta; it was, however, known to Friar Bacon, in the 13th century.

CAMERALI'STICS. (Lat. camera, *a chamber*.) A word that has recently been introduced into the English language to signify the science of public finance. It is of German origin (the equivalent term in that language being *Kammeralien*), and derives its signification from certain officers (called Kammer-räthe) appointed by most of the petty princes of Germany to superintend their accounts, and disburse all payments.

CA'MERATED. (Lat. camera.) A term applied to the shells of certain Cephalopods which are divided by transverse partitions into a series of chambers which are traversed by a siphon. Most of the species are now extinct.

CAMERO'NIANS. The strictest sect of Scottish Presbyterians; so called from the Rev. Richard Cameron, one of the most eminent of their leaders. The origin of this sect is briefly told. Charles II., on his restoration in 1660, found presbytery to be the existing national church; and though he had, at one time, sworn to maintain that faith, yet thinking it incompatible with monarchical government, he lost no time in superseding it, and establishing episcopacy in its room. This he did in direct opposition, not merely to his own solemn obligations, but to the principles and predilections of his Scottish subjects. And the result was such as might have been anticipated. The presbyterian clergy, though driven from their parishes and deprived of their incomes, continued to preach and hold meetings, or *conventicles*, as these assemblages were contemptuously called, for the celebration of religious ordinances; and their influence with the people seemed to increase in proportion as means were taken to silence or crush them. Under these circumstances, Charles, finding that rigour failed in producing the effect at which he aimed, and the number of episcopalian ministers being insufficient to fill the vacancies that had been occasioned by his violent change of the national religion, had recourse to a plan, ostensibly liberal and mild, but which did by no means realize the views which he had anticipated from it. In 1669, he granted what he called an *indulgence*, or permission to such of the ejected ministers as had meanwhile "lived peaceably and orderly," or, in other words, who had not signalized themselves by holding conventicles, to return to their several parishes (if these were vacant), or to accept presentation to such other parishes as were vacant. A similar indulgence was issued in 1672; but both of them were marked by restrictions and conditions which were any thing but agreeable to tender consciences. (*Wodrow's Church Hist.* 8vo ed. vol. ii. p. 130-31.) This indulgence emanated solely from the king, and had not been submitted to the consideration of the church, and was, in consequence, regarded by many as tantamount to a recognition of the royal authority in matters *ecclesiastical* as well as civil, and as subversive both of the national covenants (*Acts of Assembly, apud* an. 1649), to which they had sworn, and of presbytery itself, which acknowledged no head but Jesus Christ. Some of the more moderate of the clergy, however, did not think it inconsistent either with their vows or principles to accept it; others complied with it, regarding it as an encroachment on their religious rights, but satisfying their conscience by giving an open testimony against it and the ecclesiastical authority assumed by the king; while there were some who preferred principle to expediency, and peremptorily refused compliance on any terms, and resisted every effort to procure their acquiescence. These were the persons who were afterwards denominated Cameronians. (*Wodrow*, iii. 202.)

The Cameronians were influenced in the line of conduct which they pursued solely by conscientious motives. Rather than acknowledge the authority of the king in matters ecclesiastical, or abate one iota of their indefeasible rights and privileges, they were willing to separate from their conforming brethren, and to encounter all the evils and disabilities which such a step had evidently a tendency to produce. They became at once the object not only of the disapprobation of their indulged brethren, but of the vindictive and cruel rage of a tyrannical government. On the principle that "oppression drives a wise man mad," they pushed their views to the utmost extremity; and, while they vilified the Presbyterians whose opinions, both religious and ecclesiastical, were more moderate than their own, they stigmatized the king and government as unscriptural and Erastian. In short, while they arrogated to themselves absolute liberty of conscience and of judgment, they exhibited the greatest intolerance towards others who entertained different sentiments. When persecuted and proscribed, when many of them were imprisoned, and not a few of them suffered martyrdom, they began to consider their king as a tyrant; and they publicly declared, that "by his perjury in violating his covenanted vows, by his arbitrary government, and his usurpation over their civil and religious liberties, he had dissolved their allegiance and forfeited all right and title to the crown." (*Laing's Hist. of Scot.* vol. iv. p. iii.) They also protested against the succession of his brother, on account of his popery and his breach of covenant to God and the church. To these sentiments Cameron, their leader, and a party of about twenty others, all armed, gave public utterance in a *declaration* read at Sanquhar, and affixed to the market-cross of that town. (*Wodrow*, iii. 312.) This was the signal for more prompt and decisive measures on the part of government. The party were soon after (20th July, 1680) surprised at Airsmoss, a morass on the confines of the counties of Ayr and Dumfries. Cameron and his brother fell on the field; while sixteen were taken prisoners, and soon after perished as traitors on the scaffold; the remainder of the party, with some peasants who had joined them, fled. But their spirit was not intimidated, nor was their enthusiasm abated. Cargill, who was now their leader, and who was shortly after apprehended and publicly executed, pronounced at a public meeting of the party at Torwood, near Stirling, a solemn excommunication against their persecutors, including the Duke of York and the king himself. (*Hind Let Loose, passim; Laing*, iv. 112-13.)

Meanwhile, the Cameronians had formed themselves into a more regular body; and, in 1681, agreed to hold quarterly or more frequent meetings, and took the name of *The Societies United in Correspondence.* They thus acted more in concert; and their fortitude and zeal became, if possible, more intense. They were now altogether alienated from the indulged ministers and the general public; and their meetings for religious worship and for the celebration of ordinances were, for the sake of safety, confined to the mountains, or to sequestered and remote spots. They still continued the objects of the most ruthless persecution. But while proscribed and chased like beasts of prey by the government, no respect being shown to age or sex or condition, and while numbers of them, including their most popular ministers, perished on the scaffold or at the stake, they began to disagree among themselves. Some of them having been dissatisfied with the language of the *Sanquhar Declaration*, certain portions of it had been amended or explained. A considerable number took offence at the violence of Renwick, now at the head of the party; and not only separated from them, but published testimonies against some of their proceedings. The one party were averse to unite with such as would not go to the same extreme as themselves; while the other, more moderate in their principles, were for making common cause with all who held the same general sentiments, and were exposed to the same persecutions. It was at this period (1687) that Renwick drew up their *Informatory Vindication*, which in spirit was the same as the *Sanquhar Declaration.* But the breach was never healed. It is unnecessary, however, to give a more minute account either of their proceedings or their sufferings. Renwick, who was beheaded in 1688, was the last Scottish martyr. The revolution put an end to the sufferings of the Cameronians, and to persecution for conscience' sake. (*Scotch Worthies*, § Renwick, Hackston of Rathillet, &c.; *Hind Let Loose.*)

The services of this proscribed party at this crisis were of an important kind. Suffering as they had long done at the hand of a sanguinary government, and alive as they were to the value of civil and religious liberty, they espoused the cause of the Prince of Orange with an enthusiasm and bravery worthy of their character. A regiment of 800 Cameronians was speedily raised; and their heroism as displayed at Dunkeld and other places has extorted the praise of history. A regiment bearing the name still exists. (*Laing*, iv. 194. 208. 232.)

But the Cameronians, though they occupy a prominent place in the history of the reigns of Charles, and of James II. his successor, never formed a very numerous body. After the revolution, when they were allowed to worship God according to their conscience without fear or danger, they gradually became an obscure as they were a small sect. Nor did they think of forming themselves into a regular church till 1743, when, under the direction of the Rev. M. M'Millan * and other leaders, they "formed and established a presbytery in the name of Christ, the alone king and head of the church, under the title of the Reformed Presbytery." As they became more numerous, they took the title of the Reformed Presbyterian Synod. But at this moment (1841) the synod consists only of six presbyteries, embracing thirty-five congregations, most of them being very small.

The nature of the tenets and doctrines of the Cameronians may account for their never having become a numerous sect. They denied the authority of civil rulers, unless these had sworn and subscribed the national covenants; and of course they refused to include the names of such rulers, even that of the sovereign himself, either in their public or private prayers. They contended that the civil magistrate is bound to suppress error, and to encourage the true religion; and that the covenants are binding on all posterity. These opinions, however, they have gradually modified or abandoned. They now pray for the sovereign and civil magistrates, and have virtually renounced the covenants. They are also in favour of a national church; and would have no hesitation to unite with the present established church of Scotland

* They are often called *M'Millanites*, in honour of this person. They are also known by the name of *Hills People*, from the circumstance that, till within the last fifty years, they held public worship almost exclusively in the open air on the side of some hill, in honour of their persecuted forefathers in the time of Charles II. This practice they have now laid aside, and avail themselves of stone edifices for churches like other sects. *See* MACMILLANITES.

if patronage was abolished, and if the right of electing their own ministers were conferred on the people. They adopt the Westminster Confession of Faith, and all the standards and formulas of the church of Scotland. Their ministers are strict disciplinarians, adopt the Calvinistic creed in its most rigid sense, are peculiarly assiduous and faithful, and as a body the Cameronians now form a most unobtrusive, respectable, and exemplary sect of Christians.

CA'MISARDS. In French History, the Protestant insurgents in the Cevennes, after the revocation of the edict of Nantes, were so called, from having worn their shirts over their dress by way of disguise on the occasion of some nocturnal attacks. Their principal leader, Cavalier, succeeded so far as to effect a capitulation in their favour with the French government. He subsequently entered the English service, and at his death was governor of Jersey.

CA'MLET. A stuff or cloth, consisting of a mixture of wool and silk, or of wool and camel's hair.

CAMO'ENÆ. (Derivation unknown.) A Roman appellation of the Muses.

CAMP. In the art Military, a word of doubtful etymology, signifying the station of an army, with its artillery, baggage, and other appendages, when it has taken the field for the purposes of war. The history of camps involves that of the military art in all ages and in all countries; and in proportion to the skill displayed by any nation in the science of castrametation, may an accurate estimate be formed of its attainments in other departments of military tactics. The Lacedæmonians appear to have been the first people in profane history who directed their attention to this subject. Their camps, whenever it was practicable, were of a circular form, which was said to possess the advantage that from the centre, where the general with the flower of the troops lay, help could soonest be afforded to any point menaced by the enemy. The other states of Greece, Macedonia, and Carthage borrowed the grand principles of choosing and tracing their camps from the Lacedæmonians; but accommodated the form, the arrangement, and disposition of the same to the nature and strength of the ground which they intended to occupy. It was from the Romans that the art of castrametation first acquired any systematic regularity. The form of the Roman camp was invariably quadrangular; it was surrounded by regular intrenchments, and was so admirably arranged that each cohort, legion, and individual knew exactly the point which he ought to occupy, and the part to which instant attention should be directed in the event of alarm. It would exceed our limits to give an account of the construction of the Roman camps, and of the arrangement of the troops in them. The reader will find ample details and comments upon this subject in the works of Polybius and Vegetius, and in General Roy's *Military Antiquities of the Romans in Britain.* The *Penny Cyclopædia* contains an able account of the different systems of castrametation.

CAMP. In Agriculture, a heap of turnips, potatoes, or other roots, laid up for preserving through the winter; in some places called a *pie*, and in others a *bury*.

CAMPAI'GN. (Fr.) An uninterrupted series of military operations in the field. *See* WAR.

CAMPANI'LE. (It. campana, *a bell.*) In Architecture, properly a tower for containing a bell or bells. Though the word has been adopted in the English language, and applied to the bell towers of churches, it more properly belongs to those towers near churches, but detached from them, to be seen in many of the cities of Italy. The principal of these are the Campanile of Cremona, which is of the extraordinary height of 396 feet; that of Florence, 268 feet high, built from the design of Giotto; the Garisendi tower at Bologna, built in 1110, which is 147 feet high, and is 8 feet 8 inches out of an upright; and very near to it in the same city another tower, bearing the name of Asinelli, 327 feet in height, and leaning from the perpendicular 3 feet 8 inches, but which, seen, as it always is, in company with the first, seems to lean but little. The last we shall name is that which is commonly called the leaning tower of Pisa, and perhaps the most remarkable of all. It is 151 feet high, and overhangs 12 feet 9 inches. Its general form possesses elegance, and is that of a cylinder encircled by 8 tiers of columns over each other, and each with an entablature. The columns are all of marble, and the upper tier is recessed back.

CAMPA'NULA. (Lat. campana, *a bell.*) A very large genus of hardy herbaceous plants and annuals, inhabiting the temperate parts of both the eastern and western hemispheres, but most abundant in the latter. They have blue or white flowers, often of considerable size, on which account most of the species are favourites in gardens. In M. Alphonso de Candolle's account of the genus, published in 1830, after separating from it several groups, 152 species are enumerated. The only useful plant among them is *C. rapunculus*, the radish-like sort of which is sometimes eaten under the name of Rampion.

CAMPE'ACHY WOOD. Logwood. Brought from *Campeachy*, in the bay of Honduras.

CAMPHE'NE, or CAMPHOGEN. A term applied by chemists to a hydrocarbon, composed of ten atoms of carbon = 60, and eight of hydrogen = 8; it is therefore represented by the equivalent number 68. It is identical with pure *oil of turpentine;* and camphor is its protoxide, that substance being composed of 68 camphogen + 8 oxygen; camphor is therefore represented by the equivalent number 76.

CA'MPHOR. A concrete volatile and highly odorous substance, obtained by distillation from the *Laurus camphora*, or camphor laurel, which is a native of Japan. It is also found ready formed in the wood of the *Driabalanops camphora*, a tree which flourishes in Borneo and Sumatra. What is called *crude* or *rough* camphor is in small grey pieces and crystals; it is purified by sublimation, and is found in commerce in circular cakes weighing about 8 lbs. each, white, translucent, and somewhat tough and crystalline in texture. Camphor is chiefly used in medicine: it dissolves very sparingly in water, and the solution is called *camphor julep;* it dissolves abundantly in alcohol, forming *camphorated spirit of wine.*

CA'MPHORATES. Compounds of camphoric acid.

CAMPHO'RIC ACID. An acid obtained by boiling camphor in nitric acid. It consists of 60 carbon, 8 hydrogen, and 5 oxygen; or of one atom of camphor and four atoms of oxygen.

CA'MPULI'TROPOUS. (Gr. καμπτω, *I curve*, and τρεπω, *I turn.*) In Botany, a name given to such ovules as bend down upon themselves till their apex touches the base. They are extremely common in plants, and are more particularly those in which a *raphé* exists; the latter being a bundle of vessels, whose office is to maintain a communication between the base of the nucleus and the base of the seed.

CANA'L. (Lat.) An artificial channel filled with water, formed for the purposes of draining, of irrigation, of supplying towns with water, or of inland navigation. Illustrative of the first, may be cited the canal which extends from the Fúcine Lake (now Lake Celano) into the river Liri; of the second, the canals with which ancient Egypt was intersected; of the third, the artificial aqueducts of antiquity, or in modern times the New River, by which London is in a great measure supplied with water from Hertfordshire; but it is to channels for the purpose of inland navigation that the term *canal* is usually confined.

That the importance of canals as a means of inland navigation attracted attention even in the earliest ages, is manifest from the "fossæ Philistinæ," large canals (*Pliny*, iii. 16.) at the south of the Eridanus in Liguria, the origin of which is ascribed by Mr. Bryant to the Canaanites, who at an early period migrated from Philistia; as well as from the grand design of the Cnidians, a people of Caria in Asia Minor, to dig a channel through the isthmus which joined their territory to the continent. (*Her.* ii. 78.) The attempt, too, of the Egyptians at a later period to unite the Nile with the Red Sea by a canal has been often recorded, though it is difficult at the present day to discover the least traces of its existence. The Greeks, who received the first principles of commerce and the arts from the Egyptians and Phœnicians, and who, improving upon the models transmitted to them, afterwards reached an unexampled pitch of civilisation, conceived the magnificent design of making a navigable passage from the Ionian Sea into the Archipelago, by cutting a canal across the isthmus of Corinth. This undertaking, however, proved abortive; and though the attempt was again renewed by several of the Roman emperors, it still remained without success. In the reign of Augustus, Drusus succeeded in excavating a canal from the Rhine to the Issel, and formed, as we are told by Pliny, a new mouth from the Rhine to the sea. A canal between the Rhine and the Maese, supposed to be that now commencing at Leyden and passing Delft to its junction with the Maese at Sluys, was likewise formed by the Romans. But, as has been often observed, it was by bending nations under the same yoke, and not by uniting them in commercial ties, that the Romans sought to extend international communications; hence their canals were usually formed for the purposes of draining or of warfare. There can be little doubt, however, that it was the Romans who introduced into their provinces the models of internal communication which in modern times have undergone such immense improvement, and which have been converted to a purpose nobler than conquest — the interchange of the productions of labour.

There is no country in the world where the advantages of canals are more appreciated than in China. From time immemorial the rivers that intersect that vast empire have been united by innumerable canals; and the Grand Canal is said to be the most stupendous work of the kind that has ever been executed. (*Raynal, Hist. Phil.* i. 102.) Russia, too, exhibits a remarkable degree of enterprise in the construction of canals for the

purpose of inland navigation; and though innumerable difficulties peculiar to that country for a long period impeded the progress of works of this description, that empire is now traversed by an unbroken line of water communication from St. Petersburg to the Caspian Sea.

The canals constructed during the period of the glory of Italy are very numerous; but though many of these are navigable, their primary object has been to communicate to both banks of the Po the various productions of the country.

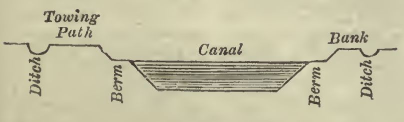
In the Netherlands, the construction of canals commenced in the 12th century, when Flanders became the commercial entrepôt of Europe; and to the large share which canals possess in its economical arrangements is to be ascribed chiefly the prosperity of Holland in the present day. From the structure of that country, canals are formed with peculiar facility; and there is not a town or a village which is not furnished with a canal of greater or smaller dimensions. France has from a distant period exercised its skill in the construction of canals for inland navigation. The first was the canal of Briare, which opens a communication between the Loire and the Seine, and then between Paris and the western provinces, and is of immense importance in inland commerce. Omitting many works of this kind, completed, in progress, or projected in that country, the canal of Languedoc may be mentioned, which was intended to unite the Mediterranean with the Atlantic, and was considered a stupendous undertaking. It is 150 miles long, is supplied by a number of rivulets, and is provided at proper intervals with 114 locks and sluices.

A reference to the earlier history of Spain, Sweden, and Denmark, and to the more recent accounts of Austria, Prussia, and above all America, will show to what extent these several states have endeavoured by the construction of canals to develop internal resources, and to distribute universally the productions of labour.

It is a singular circumstance that Great Britain, generally foremost in the race of civilisation, and possessing so many natural means for the formation of canals, from its insular position and its numerous rivers, was the last country in Europe to avail itself of its advantages. It is true that at different periods of our history the importance of inland navigation was deeply felt, and various expedients were adopted for removing obstructions in the rivers of England, with the view of facilitating internal commerce; but it was not till the middle of the last century that the construction of canals began to enter into the system of British economy. In the year 1755 an impulse was given to the progress of British industry by the project, which originated with the Duke of Bridgewater, of forming a canal between Worsley and Manchester; a project which was altered and extended by three successive acts of parliament to admit of greater comprehensiveness in its execution, and has formed the basis of every succeeding plan of canalisation in this country. The example then set by the Duke of Bridgewater was speedily followed: the large amount of capital in England, which is ever ready to be invested in undertakings that are likely to prove profitable, soon found its way into this channel, and in a short time the country became intersected with navigable canals.

The section of a canal is usually a trapezium, of which two sides are parallel and horizontal, and the other two equally inclined to the horizon. The inclination depends on the nature of the soil. It is least in tenacious earth, and greatest in loose soil; but no soil will maintain itself, unless the base of the slope exceeds its height at least in the ratio of four to three. In loose soils the base requires to be twice as great as the height.

A canal is usually confined between a bank on one side, and a towing path on the other, the breadth of whose upper surface must be sufficient for a road on which the animals employed in draught may easily pass. This requires the breadth of the upper surface to be at least 9 feet. The usual rule for the other bank is to make the breadth at top equal to the height, measured from the bottom of the canal: but in this case there should be a *berm* of a foot, or a foot and half, at the level of the water, which increases the thickness of the bank at bottom, and prevents the wash of the banks from falling into the canal. To prevent the entrance of rain-water, a *counter-ditch* is formed on the outside of each of the banks. The profile of a well-constructed canal will therefore present the following figure:—



The dimensions of navigable canals must depend on the size of the vessels intended to navigate them. In order that they may permit two vessels to pass each other with freedom, the breadth at bottom is usually made twice as great as the breadth of the beam of the vessels: the depth requires to be at least one foot more than the vessel's draught of water.

The bed of a canal must be absolutely level, or have no more slope than is necessary to convey water to replace that which has been wasted. Hence, when a canal intersects a sloping country in a series of channels at different levels, means must be provided to enable vessels to pass from one level to another. This is commonly effected by means of a *lock*.

The invention of locks as a means of carrying a canal through an undulating country has given an entirely new feature to the inland navigation of Europe. Various nations have claimed the honour of this invention; but it would appear that the controversy which has arisen on the subject is not yet settled. "A lock is a chamber, formed of masonry, occupying the whole bed of the canal where the difference of level is to be overcome. This chamber is so contrived that the level of the water which it contains may be made to coincide with either the upper or lower level of the canal. This is effected by two pairs of gates, one of which pairs is placed at each end of the chamber of the lock. By this means, while the gates at the lower end of the chamber are opened, and those at the upper end are closed, the water in the chamber will stand at the lower level of the canal; and, on the contrary, when the lower gates are closed, and the upper gates are opened, the level of the water in the lock will coincide with the level of the water in the upper part of the canal. In the first case, a boat may be floated into the lock from the lower part of the canal; and if then the gates be closed, and water is admitted into the lock from the upper level until the surface of the lock is in a line with the water above, the boat will be floated up, and on the opening of the upper gates may be passed onward. By reversing the course of procedure, boats may be as readily conveyed from the upper to the lower level." *See* LOCK.

The supply of water required for maintaining a canal depends on the *lockage* or quantity wasted in passing a vessel through the locks, on the evaporation from the surface, and on the leakage. It has been found by experiment that the annual quantity of evaporation from the canal of Languedoc is 32 inches; that is to say, the body of water required to supply this waste is equal to a parallelopiped whose base is the whole surface of water in the canal, and whose altitude is 32 inches: in most calculations it has been customary to take this altitude at 36 inches. With respect to the leakage, when the soil is porous the inner surface of the banks may be lined with an earth retentive of water, or a portion of the middle of each bank may be built up with earth of this character. The operation of lining a bank with clay, or earth retentive of moisture, is called *puddling*.

The advantages derived from canals are now so generally known and acknowledged, as to render it almost superfluous to allude to the question. The beneficial effects of canals are felt in a greater or less degree by all classes of society: by their means the manufacturer is enabled to collect his materials and his fuel with less labour and expense; the farmer obtains a supply of manure at a cheap rate, and a ready conveyance of his produce to the most profitable market; and the merchant is enabled to extend his commerce by exporting greater quantities and varieties of goods from places remote from the sea, and by more easily supplying a wider extent of inland country with articles of foreign produce. In short, general arguments in favour of canals are superseded by the rapidly improving and thriving state of all the cities, towns, and villages in their neighbourhood; while the great works of every kind to which they have been conducted, and to which a large portion of them owe their rise, are their best recommendation. Some years ago, when the formation of railroads became a favourite speculation, no small degree of alarm was experienced by those interested in the prosperity of canals, lest they should diminish in importance, or in fact be entirely superseded by the introduction of railroads. Experience has, however, hitherto shown that the fears entertained on this subject were perfectly groundless; for, as railways are constructed chiefly for the expeditious transport of passengers and goods, and from the expense incurred in their construction and maintenance a higher rate of toll must be levied in order to pay the proprietors, this mode of conveyance is not likely to interfere with that description of goods which form the chief traffic of canals, and for which *cheapness*, not *expedition* of transport, is required. (For detailed information on the subject of canals, the reader is referred to *Phillips's General History of Inland Navigation;* and to *Nichols, Priestley, and Walker's Historical Account of the Navigable Rivers, Canals, &c. of Great Britain.*)

CANALI'CULATE. (Lat. canalis, *a water pipe.*)

In Zoology, is said of a surface when it has a longitudinal impressed line or channel.

CANALI'CULATE. (Lat. canalis, *a water pipe.*) Is said of leaves or other parts when the edges are so much turned upwards as to produce the appearance of a channel or gutter.

CANALI'FERA. (Lat. canalis, *a canal;* fero, *I bear.*) The name of a tribe of Zoophagous Univalves, or Gastropods, of which the shell is characterized by a long straight canal terminating its mouth.

CANA'RY-BIRD. Two distinct species of finch (*Carduelis*) appear to have afforded the different varieties of singing bird familiarly known by this name. The one which is best known in its wild state is the *Carduelis canaria* of Cuvier, and is very abundant in Madeira, where its characters and habits have been observed with much attention by Dr. Heineken. "It builds," says this naturalist, "in thick bushy high shrubs and trees, with roots, moss, feathers, hair, &c.; pairs in February; lays from four to six pale blue eggs; and hatches five, and often six times in the season. It is a delightful songster, with, beyond doubt, much of the nightingale's and sky-lark's, but none of the wood-lark's song."—"A pure wild song from an island canary, at liberty, in full throat, in a part of the country so distant from the haunts of men that it is quite unsophisticated, is unequalled, in its kind, by any thing I have ever heard in the way of bird-music." The canary-bird was brought into Europe as early as the 16th century, and is supposed to have spread from the coast of Italy, where a vessel, which was bringing to Leghorn a number of these birds besides its merchandise, was wrecked. As, however, they were males chiefly which were thus introduced, they were for some time scarce; and it is only of late years that their education and the proper mode of treating them have been known.

CANA'STER. The rush basket in which tobacco is packed in Spanish America; whence *canaster tobacco.*

CA'NCEL. (Fr. canceller.) In Printing, is the suppression of a leaf or more of a book, owing to some error of importance having escaped detection, or some fact being mis-stated, or some new discovery being made, or some change having taken place in the author's arrangements after that part of a work has been printed, and substituting for the portion cancelled a corrected leaf, &c. which is usually distinguished by one of the following signs at the bottom of the page, *, †, ‡, §, as a guide to the bookbinder.

CANCELLA'RIA. (Fr. canceller.) A Lamarckian genus of Trachelipod Testacea, having the shell oval or turreted; base of the aperture sub-canaliculate; canal very short; columella plicate; the plaits usually transverse, varying in number; lip internally furrowed; operculum horny. The reticulated Cancellaria (*Cancellaria reticulata,* Lam.) is a well-known species, from the Atlantic Ocean.

CA'NCELLATE. (Lat. cancelli, *lattices.*) Is a term applied to leaves consisting entirely of veins, without connecting parenchyma; so that the whole leaf looks like a plate of open network. Instances of this kind occur in *Hydrogeton fenestralis,* but are extremely rare.

CA'NCER. (Lat.) The *Crab.* The fourth sign of the zodiac, which the sun enters about the 21st of June, when he reaches his greatest northern declination. The parallel circle through this point is called the *Tropic of Cancer.*

CANCER. The Linnæan generic name for the modern Brachyurous family of Crustaceans.

CANCER. A disease chiefly attacking the glands, consisting of a schirrous tumour, terminating in an ill-conditioned and deep ulcer, generally attended by excruciating pain. When the cancerous character of a tumour is once ascertained, its extirpation, where practicable, is the only chance of effectual relief. The large blue veins which ramify round a cancer of the breast were compared by old authors to the claws of a crab, whence the name of this disease.

CANCRO'MA. A genus of *Grallatores* or wading birds, belonging to Cuvier's family of *Pressirostres,* or compressed-billed waders, including only one known species, the Boatbill; so called from the form and structure of the bill, which characterizes the genus. The bill is flattened or depressed, not compressed; and is composed of two boat-shaped or spoon-shaped mandibles, with their concavities applied towards each other, the upper one having a strong and sharp tooth near the point. The Boatbill inhabits the banks of the Orinooko, and other large rivers of South America which are subject to flooding in the rainy season.

CANDELA'BRUM. (Lat. candela, *a lamp or candle.*) A stand or support on which the ancients placed a lamp. Candelabra varied in form, and were highly decorated with the stems and leaves of plants, parts of animals, flowers, and the like. There was no article of ancient furniture in which more taste and elegance were displayed than in the designs of candelabra. The etymology of the word would seem to assimilate the candelabrum to our candlestick; it is, however, quite certain that the word *candela* was nothing more than a lamp, and that the candelabrum was but a support more or less heavy in construction upon which the lamp was placed, or whose top was hollowed out for the reception of oil or some other combustible. The great variety observable in ancient candelabra was not so dependent on the caprice of the artist, as on the different uses to which they were first applied. Before the employment of oil the mode of illuminating an apartment was by means of dry wood burnt on *braziers* (basins for holding fuel) supported by tripods. The Greeks, always delighting to preserve some reminiscence of an ancient usage, thence adhered to the triangular form in this article of furniture, and their example was imitated by the Romans. Generally speaking, there are two species of candelabra: those which ending upwards in the form of a brazier, so nearly approach the form of a portable altar as to be almost confounded with it. This species must be classed with the tripod, and there seems ground for believing that it was used only in temples or in small chapels. Of this sort was that carried off by Verres; and Cicero informs us that in Sicily every house was supplied with one in silver. Of this species also are those most frequently sculptured in friezes, usually accompanied by genii and instruments of sacrifice. The other species of candelabra, whose accessaries and ornaments are of the same character as in those first described, are much higher, and of marble. Of this kind Rome furnishes an abundance of examples; but, as Winkelman observes, not one has been found in bronze.

The marble candelabra exhibit as much variety in the forms of the vase or brazier, which it is their principal end to support, as in the body and base of the support itself. Sometimes they are capricious to excess, the foliage, contrivance, and design being such as to display more skill than propriety of taste. Others, however, there are which are exquisite models of form, taste, ornament, and execution. The museum at the Vatican contains possibly the finest collection in Europe of this species. There is one to be seen there upwards of seven feet high, resting on griffins' or lions' paws. The general form of its shaft is that of a baluster, which supports a vase-shaped basin; it is highly decorated with foliage and bassi-rilievi of bacchantes. Our British museum presents some specimens; beautiful, but not of the first class. For full information on this species, the reader should turn to the splendid works of Piranesi. Lachausse thinks that marble candelabra were used in temples more for the purpose of adding splendour to the service than of lighting it; but it seems probable that many with which we are acquainted, such as those that were found in the baths of Titus, where numbers of the apartments did not receive the light of day, actually held artificial light. The most curious specimens of candelabra, as respects form, use, and workmanship, are those excavated at Herculaneum and Pompeii. These are all of bronze; and that they were employed for domestic purposes is proved from the representation, on an Etruscan vase, of one which serves to give light to the guests assembled round a banquet table. They are slender in their proportions, and perfectly portable, rarely exceeding five feet in height. It is to be observed, that none of the candelabra hitherto found exhibit any appearance of a socket or of a spike at top, from which an inference of the use of candles could be drawn.

CANDIDA'TI. (Lat. candidus, *white.*) In Roman Antiquities, so called from their being arrayed in white garments, were the aspirants for public offices. In this dress they canvassed the different tribes, harangued the people, extolled their own exploits, and, as the case might happen, exhibited the wounds which they had received in the service of their country. The forms of election among the Romans were remarkably strict. Every candidate for public offices was compelled to pass two years in probationary service; and even then his appointment, which could only be ratified by numerous and imposing solemnities, did not generally take place until he had spent five months as magistrate elect in familiarizing himself with the duties of his office. Notwithstanding the severity of the Roman laws against corruption, the practice of bribery was constantly resorted to, and a full purse and fair promises went far to supply the want of ability and integrity.

CA'NDLEMAS. A church festival, held on the 2nd of February, to commemorate the purification of the Virgin. The name probably arose from the number of lighted candles used in the processions of the day; or perhaps from a custom of consecrating candles on that day for the rest of the year. This practice was abolished in England in the second year of the reign of Edward VI.

CA'NDLES. These are an important article of manufacture, and may be composed of a variety of materials: the principal are,—1. *Wax candles,* which are made by pouring melted wax over the wicks, which for the convenience of turning and placing them successively over the cauldron, are usually attached to the circum-

ference of a hoop; when of a proper thickness, they are rolled smooth upon a table, and the ends are cut and trimmed. It is in consequence of this method of manufacture, that when we cut a wax candle we observe it composed of successive layers or coats. Attempts have been made to cast wax candles in moulds, but those which are thus made never burn so well as those which are *poured*. 2. *Spermaceti candles*, or mixtures of wax and spermaceti. This material forms a very good and cleanly candle; but in consequence of its ready fusibility and hardness when concrete, it does not admit of being carried about without spilling the melted material. The fused portions also, which run down the candle, are apt to curl up and fall upon the table. 3. *Composition candles*. This term was originally conferred by a manufacturer who had a large stock of spermaceti candles on hand which were of a dirty hue, and which therefore were unsaleable; he advertised them under the above name, and they were soon disposed of, under the notion of their being composed of some new combination of materials. The term has since been applied to various mixtures; but what are now sold under the name of composition candles are chiefly mixtures of spermaceti, tallow, and a little resin, and occasionally wax. 4. *Tallow candles*, which are either cast upon the wick in pewter moulds, or made by dipping the wicks, attached in rows to proper frames, into melted tallow. 5. *Stearine candles*. Under this term we may include cocoa-nut oil candles, and a few others made of the stearine, or what may be compared to the *spermaceti* of the vegetable oils. The stearine, or rather the *stearic acid* of tallow, is also now extensively employed for making candles.

A candle may be considered as a portable gas apparatus, and its philosophical history involves a number of very curious points, which we can only superficially advert to here. The combustible material, in a state of fusion, is drawn up in successive portions by capillary attraction into the heated part of the wick, the texture, materials, and dimensions of which are matters of much importance. If the wick be too large, the candle flares and smokes, producing a peculiar suffocating smell in the room, and often wanting snuffing, as we constantly see in badly made mould candles; if, on the contrary, the wick be too small, the candle burns dimly and gutters, in the former case, unburned carbon soon collects in the upper part of the flame, and if not removed is apt to fall into the cup of the candle, where it forms a kind of second wick, rapidly melting away the tallow and disfiguring the candle, and occasionally, where candles are inadvertently left burning, falling upon the table and setting fire to any thing within its reach. This evil may to a great extent be prevented by inclining the candle at an angle of about 45 degrees, so as to keep the upper part of the wick out of the flame. In this way the air has access to it, and the charcoal which otherwise collects into a head is burned as soon as deposited. Where it is required to keep a common tallow candle burning during the night, the necessity for snuffing, and the risk of mischief, may be prevented by so inclining it; and candlesticks have been contrived for the purpose, which are useful and effective, but very unseemly. With good wax the wick is more easily adjusted to the wants of the flame, and the necessity of snuffing to a great extent prevented; but adulterated wax is often more troublesome than tallow. Great care is also requisite in selecting the cotton for the wicks of candles, which should be of such a nature as to leave no ash, or scarcely any, when burned. The wick is occasionally impregnated with different substances, and sometimes so platted as to curl out of the flame; but the details of these contrivances would be foreign to the object of this work. The following table contains the results of some experiments made by Dr. Ure, with a view of ascertaining the relative intensities of light and the duration of different candles: —

Number in a pound.	Duration of a candle.	Weight in grains.	Consumption per hour in grains.	Proportion of light.	Economy of light.	Candles equal to one Argand.
10 Mould	5h. 9m.	682	132	12·25	68·0	5.70
10 Dipped	4 36	672	150	13·00	65·5	5·25
8 Mould	6 31	856	132	10·50	59·5	6·60
6 Ditto	7 2½	1160	163	14·66	66·0	5·00
4 Ditto	9 36	1787	186	20·25	80·9	3·50
Argand oil flame		- -	512	69·40	100·0	

In reference to the above table, it appears from Dr. Ure's experiments that one-eighth of a gallon of good oil, weighing 6010 grains, or 13 and 1-10th ounces avoirdupois, lasts in a bright argand lamp 11 hours 44 minutes. The weight of oil it consumes per hour is equal to four times the weight of tallow in candles eight to the pound, and 3 and 1-7th times the weight of tallow in candles six to the pound; but, its light being equal to that of five of the latter candles, it appears from the above table, that 2 lbs. weight of oil, value one shilling, in an argand lamp, are equivalent in illuminating power to 3 lbs. of tallow candles, which cost about three shillings. The larger the flame in the above candles, the greater the economy of light. (*Ure's Dictionary of Chemistry.*) In reference to the comparative cost of coal gas, oil, tallow, and wax, it appears that the cost of a lamp fed by gas, and giving the light of seven candles, will be about one penny per hour; of an argand lamp fed with spermaceti oil, about threepence; of mould candles about threepence halfpenny; and of wax candles about one shilling. Ninety cubic feet of good coal gas, value about one shilling, will produce the light of about 10 wax candles for one hour.

CANE'LLA. (Dim. of canna, *a reed.*) The bark of the *Canella alba*, imported from the West Indies in quilled pieces of a pale buff colour, and a biting aromatic flavour. It is occasionally used in medicine.

CANE'LLEÆ. (Canella, one of the genera.) A small natural order of plants, supposed to be related to *Clusiaceæ;* but very imperfectly known. They consist of South American shrubs or trees; one of which, *Canella alba*, is aromatic, and yields the wild cinnamon of the West Indies. The bark of that species is used medicinally against scurvy.

CANE'PHORÆ. (Gr. κανηφόρος, *bearing a basket.*) In Architecture, figures of young persons of either sex, bearing on their heads baskets containing materials for sacrifice. They are frequently confounded with caryatides, from their resemblance in respect of attitude and the modern abuse of their application. *See* CARYATIDES.

CA'NES VENA'TICI. The *Greyhounds.* One of the constellations formed by Hevelius in the northern hemisphere. It is represented on the celestial globes and charts by the figures of two dogs, which are also distinguished by the names of *Asterion* and *Chara*.

CANI'CULAR DAYS, or DOG DAYS. The name given to certain days of the year, during which the heat is usually the greatest. They are reckoned about 40, and are set down in the almanacs as beginning on the 3rd day of July, and ending on the 11th of August. In the time of the ancient astronomers, the remarkable star Sirius, called also *Canicula*, or the *Dog Star*, rose heliacally, that is, just before the sun, about the beginning of July; and the sultry heat which usually prevails at that season, with all its disagreeable effects, among which the tendency of dogs to become mad is not one of the least disagreeable, were ascribed to the malignant rage of the star. Owing to the precession of the equinoxes, the heliacal rising of Sirius now takes place later in the year, and in a cooler season; so that the *dog days* have not now that relation to the particular position of the *Dog Star* from which they obtained their name.

CANI'CULAR YEAR. The ancient solar year of the Egyptians; so called because its commencement was determined by the heliacal rising of the Dog Star. The Egyptians chose this star for their observations, either on account of its superior brightness, or because its heliacal rising corresponded with the annual overflow of the Nile. At a very early period of history the Egyptians had perceived that the solar year contains 365¼ days; for their common years consisted of 365 days, and every fourth year of 366, as in the Julian Calendar.

CANI'NES. (Lat. canis, *a dog.*) The pointed, often long teeth, which succeed the incisors; called *dentes canini*, or *laniarii.*

CA'NIS. (Lat. canis, *a dog.*) The name of a genus of Digitigrade Mammalia, restricted in the modern systems of Zoology to the species of dog, wolf, and jackal; but by Linnæus applied in a wider sense to include the fox and hyena. With respect to the latter animal its enormously developed anal scent-glands, its brief coition, and its mane indicate it to belong to the family of the skunks and genets rather than to that of the dogs, while the prickly tongue and dentition of the hyena approximate it to the cats. The foxes are generically distinguished from the dogs by the pupils of the eye, which during the day have the form of a vertical fissure, by their less notched upper incisors, and by their longer and more bushy tail. The true characters of the genus *canis* are six incisors and two canines in each jaw, six molars on each side of the upper jaw, and seven molars on each side of the lower jaw, making in all forty-two teeth, of which there are twenty in the upper and twenty-two in the lower jaw. The first three molars in the upper, and the first four molars in the under jaw, are trenchant and pointed or lacerating teeth; the succeeding molar in the upper jaw is very large, with two sharp cutting points towards the outer edge, and a small tubercle on the inner side interiorly; the others are smaller, and all furnished with tubercles: the first of these tuberculate molars in the upper jaw is very large. In all the wild varieties of the species of canis the muzzle is elongated, and the ears are carried erect; the tongue is unprovided with cuticular spines; the fore feet have five toes, the hind feet

four only; both are armed with non-retractile claws; the cœcum is cylindrical, and coiled upon itself; the anal glands are of moderate size; the coitus is prolonged. The dog (*Canis familiaris*, L.) is distinguished from the wolf and jackal by his recurved tail; but the varieties, as to size, form, colour, and quality of the hair, are almost infinite. The dog is the most complete, singular, and useful conquest ever made by man over the brute creation: each individual is devoted to his particular master, assumes his manners, knows and defends his property, and remains attached to him till death; and all this neither from constraint nor want, but solely from the purest gratitude and truest friendship. The swiftness, strength, and scent of the dog have rendered him man's powerful ally against all other animals, and have perhaps mainly contributed to the establishment of society. Some naturalists think the dog is a reclaimed wolf, and others that he is a domesticated jackal; nevertheless, those dogs that have become wild again revert neither into the one nor the other species. The wild dogs, and those that belong to savages, as the dingo, resemble, it is true, the wolf in the shape of the head, their straight pricked ears, rough and thick hair, long bushy tail, and lounging gait; moreover, they never bark, but utter a sharp cry or long melancholy howl, like the jackal and wolf; yet they are plainly distinct from both. The Esquimaux dogs present the first traces of a deviation from the wild type; the figure of the legs is more determined, and their pace bolder and more rapid: still they manifest their near relationship to the wolf in their sharp nose, pricked ears, and inability to bark. The Esquimaux and the people of Kamtschatka use these dogs as beasts of draught: six or seven dogs will draw a sledge laden with eight or ten hundred weight at the rate of seven or eight miles an hour, and will easily, under these circumstances, perform a journey of fifty or sixty miles a day, when the snow is hard and smooth, and the road level. The dogs thus employed have a simple harness of deer or seal skin going round the neck by one bight, and another for each of the fore-legs, with a single thong leading over the back, and attached to the sledge as a trace. "Though they appear," says Captain Parry, "to be at first sight huddled together without regard to regularity, there is in fact considerable attention paid to their arrangement, particularly in the selection of a dog of peculiar spirit and sagacity, who is allowed by a longer trace to precede the rest as leader, and to whom, in turning to the right or left, the driver usually addresses himself."

The Newfoundland dog may be regarded as the next remove from the Esquimaux variety. These fine and sagacious animals are employed in their native island to draw sledges and carts laden with wood and fish, and to render many other useful services performed elsewhere by the horse. The readiness with which the Newfoundland dog takes the water, his aptitude to fetch and carry, and his powerful and active swimming, have been the means of preserving the lives of many human beings. Another variety of dog nearly allied to the Newfoundland breed, and belonging to the same subdivision (*Avicularius*, Linn., or spaniel-tribe), has been trained by the benevolent monks of the convent situated near the top of the mountain of Great St. Bernard, to hunt out and extricate such unfortunate travellers as may have been buried under the snow-drifts or avalanches, while attempting the neighbouring dangerous pass between Switzerland and Savoy. One of these noble animals was decorated with a medal in commemoration of his having saved the lives of twenty-two persons, who must otherwise have perished. In the museum at Berne is still preserved the stuffed skin of "Barry," another of these dogs, together with the bottle and collar which he bore in his lifetime; for the good fathers, with a provident care to afford every chance of escape to the unfortunate travellers, fasten a flask of spirits about the neck of the dog before he starts on his search. Barry having discovered a boy whose mother had been destroyed by an avalanche, unhurt and asleep in the hollow of a glacier, and almost stiff with cold, delivered to him the bottle suspended from his neck; and when he had refreshed himself, found means to induce him to mount upon his back, and thus carried him to the gate of the convent. This dog had been the means of rescuing from death upwards of forty persons before he was superannuated; when he was sent to pass the remainder of his days, on a pension, in a more genial climate at Berne.

In our own country the shepherd's dog offers the example of one of the purest races of the domesticated animal, and that which, in its straight ears, its hair, and tail, approaches nearest to the original stock. The sagacity of this variety in the peculiar department in which his services are rendered to man is well known, and has been illustrated by a hundred interesting anecdotes. The shepherd's dog, though outwardly resembling in many points the "dingo," possesses a greater cerebral development, which continues to increase together with intelligence in the spaniel and barbet. Guided by the form of the cranium, we should associate the spaniel and its intermediate varieties with the shepherd's dog, the wolf dog, the Newfoundland and Mount St. Bernard's dog, and the Esquimaux dogs in one family (*Sagaces*).

A comparison of the crania indicates a closer affinity of the "dingo" with the family *Pugnaces*, including the mastiff and Danish dog, than with the *Sagaces*. After the pugnaceous mastiff and its varieties, as the bulldog, remarkable for the shortness and strength of its jaws, come the hound, the pointer, and the terrier in the order of cerebral development. The varieties of this family (*Venantes*) differ between themselves chiefly in the size and proportions of the limbs; the greyhound is longer and more lank, its frontal sinuses are smaller, and its scent weaker.

The bandy-legged turnspits, and the small pet dogs, as the pugs, poodles, Italian greyhounds, king Charles's breed, &c., are the most degenerated productions of the genus, and exhibit the most striking instances of that power to which man subjects all nature.

With some exceptions among this latter anomalous group all the domestic varieties of the genus *Canis* are easily and naturally referable to one or other of the three great tribes above mentioned, of which the mastiff, the hound, and the spaniel may be regarded as the several types, and which we have named *Pugnaces*, *Venantes*, and *Sagaces*, from their prominent aptitude respectively for the combat, the chase, and those more varied and complicated services which seem to demand for their fulfilment a greater amount of intelligence in our canine auxiliaries.

In all the varieties of the dog the following circumstances in his economy are constant:—He is born with his eyes closed; he opens them on the tenth or twelfth day; his teeth commence changing in the fourth month; and his full growth is attained at the expiration of the second year. The period of gestation is sixty-three days, and from six to twelve pups are produced at a birth. The dog is old at fifteen years, and seldom lives beyond twenty. His vigilance and bark are universally known.

CA'NIS MA'JOR. (Lat.) The *Greater Dog*. One of the 48 constellations of Ptolemy, in the southern hemisphere, and under the feet of Orion. Sirius, the brightest of all the fixed stars, belongs to this constellation.

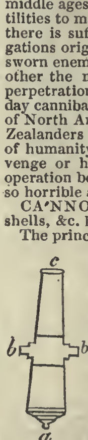
CA'NIS MINOR. The *Lesser Dog*. Is also one of Ptolemy's 48 constellations. It is in the northern hemisphere, just below Gemini. Its most conspicuous star is Procyon, of the first magnitude.

CA'NNELL COAL. (Perhaps *candle* coal, from the flame with which it burns.) A species of coal, found in most of the English collieries, especially at Wigan in Lancashire. It is difficultly frangible, and does not soil the fingers; when burning it splits and crackles, but does not cake, and leaves 3 or 4 *per cent.* of ash. It is sometimes worked into ornamental utensils, like jet.

CA'NNIBALS, or ANTHROPOPHAGI. Persons that devour human flesh. The ancient authors, but especially Herodotus, have recorded instances both of individual and national addiction to this revolting practice, as in the case of Polyphemus, the Massagetæ, and the Issedones; and though there is unquestionably a large portion of fable grafted on these traditional facts, it would be rash wholly to reject an account which the testimony of subsequent history so strongly corroborates. In the middle ages it was customary for parties engaged in hostilities to make mutual accusations of cannibalism; but there is sufficient ground for believing that such allegations originated more in a desire, natural, perhaps, to sworn enemies in those rude times, of fixing upon each other the most barbarous practices, than in any actual perpetration of this deed on either side. At the present day cannibalism is practised by some of the Indian tribes of North America, the Battas of Sumatra, and the New Zealanders; though it must be admitted, to the honour of humanity, that the most violent passions, such as revenge or hatred, or the pressure of want, must be in operation before even the wildest savage will indulge in so horrible a banquet.

CA'NNON. A military engine for projecting balls, shells, &c. by the force of gun-powder.

The principal parts of a cannon are, 1. The *breech*, which is the solid metal from the bottom of the bore or concave cylinder to the extremity of the *cascabel*, *a*. 2. The *trunnions*, *b b*, which project on each side, and serve to support the cannon in equilibrio, their axis being in the vertical plane passing through the centre of gravity, but intersecting it below that point. 3. The *bore* or cylindrical cavity. This in several sorts of cannon is made of smaller diameter towards the breech, thus assuming the shape of two cylinders united by a portion of a spherical surface. The smaller part of the bore is of such a length as to receive the maximum service charge of gun-powder, and is called the *chamber*. The entrance of the bore, *c*, is called the mouth or muzzle.



Cannon are made either of cast iron or brass, the

latter being an alloy of copper and tin in the proportion of about 10 parts of copper to 1 of tin, and called gun-metal. This has a greater tenacity than iron, but is objectionable on account of its greater density and higher price, besides being liable in rapid service to soften and droop at the muzzle, whereby it is rendered unserviceable. Since the advantage of using smaller charges of gun-powder was discovered, cast iron, though possessing less tenacity than gun metal, has been substituted for ship, garrison, and battering guns. But the the smaller species of cannon (field-pieces) continue to be made generally of brass; for by reason of the rapid cooling of the iron in small masses its strength is considerably impaired, so that it is difficult to be procured of the requisite quality.

Cannon were formerly cast with a cave or hollow, but they are now always cast solid; experience having shown that when cast solid they are stronger, and less liable to burst; that the metal is freer from honeycombs; and that the bore can be rendered more perfect, and its axis made to coincide more accurately with that of the piece. In boring cannon, the gun itself is made to revolve about the bit or borer, the size of which is successively increased.

In service cannon are mounted on carriages, by which they may be removed from place to place. They are supported on the carriage by the trunnions, about which they move as on an axle; and the form of the carriage is such as to admit of their being elevated or depressed a few degrees above or below the horizontal plane. *See* GUN, GUNNERY, HOWITZER, MORTAR.

CA'NNON BONE. In Farriery, signifies the single metarcarpal or metatarsal bone of the horse.

CA'NNON METAL. Bronze; an alloy of copper with eight or ten *per cent.* of tin.

CANOE'. A boat made of a single trunk of a tree hollowed out. Some are made of pieces of bark fastened together; these should be properly called boats. They are of various sizes, and are generally propelled by one, or if large by two or more paddles, like wooden shovels.

CA'NON. (Gr. κανων, *a rule.*) A word of various significations, of which we can only enumerate the principal.

1. In cathedral and collegiate churches there are canons who perform some of the services, and are possessed of certain revenues connected with them. These are, strictly speaking, *residentiary* canons: *foreign* canons are those to whom collegiate revenues are assigned without the exaction of any duty.

2. The laws and ordinances of ecclesiastical councils are called canons.

3. The canon of scripture signifies the authorized and received catalogue of the sacred books. The canon of the Old Test., as received by the Romanists, differs from that of the Protestant churches in regarding as inspired those books which we reject under the term Apocrypha. The catalogue received by the Jews themselves, which we adopt, was first enlarged by the Council of Carthage to the extent in which it is held by our opponents, and that decision was formally confirmed by the Council of Trent. In the canon of the New Test., however, the agreement of Christian churches may be considered unanimous. There exist a series of enumerations of the sacred books of the latter covenant in the writings of the first four centuries, the general agreement of which, and the satisfactory reasons which can be assigned in most cases of omission — there are no additions — distinctly mark the universality of the judgment of the early churches in this matter.

CA'NON. In Music, a perpetual fugue. The original method of writing this was on one line, with marks thereon, to show where the parts that imitate were to begin and end. This, however, was what the Italians more particularly call *canone chiuso* (shut), or *canone in corpo.*

CA'NONESS. A description of religious women in France and Germany. Their convents were termed *colleges*. They did not live in seclusion. The college of Remiremont was the oldest establishment of this order in France. Similar noble monasteries still exist in Germany, and the revenues and dignities of some belong to Protestants.

CANO'NICAL HOURS. Stated times of the day set apart, more especially by the Romish church, for devotional purposes. In England the canonical hours are from 8 to 12 in the forenoon, before or after which the ceremony of marriage cannot be legally performed in any parish church.

CA'NONIZA'TION. A ceremony in the Romish church, by which holy men deceased are enrolled in the catalogue of saints. The privilege of canonizing was originally common to all bishops, and was first confined to the Pope by Alexander III. in 1170. When it is proposed to canonize any person, a formal process is instituted, by which his merits or demerits are investigated. Hereupon the *beatification* of the person in question is pronounced by the Pope, and his canonization follows upon the production of testimony to miracles performed at his tomb or by his remains. The day of his death is generally selected to be kept in his honour, and is inserted as such in the calendar. The last instance of canonization took place in 1803.

CANO'PUS, or CANOBUS. (Gr. Κανωπος, the name of a place in Egypt.) A bright star of the first magnitude in the rudder of Argo, one of the southern constellations. As its declination is about 52½° south, it is not visible in our hemisphere beyond the 40th degree of latitude.

CA'NOPY. (Gr. κωνωπειον.) In Architecture, an ornamented covering over a seat of state, and in its extended signification any covering which affords protection from above.

CANT. In sea phrase, to turn over or round; a cant is also a piece of wood laid on the deck for the support of a bulk-head.

CANTA'TA. (It. cantare, *to sing.*) In Music, a song or composition intermixed with recitative, usually for a single voice with a thorough bass.

CANTHA'RIDES. (Gr. κανθαρος, *a beetle.*) Spanish flies. The *Cantharis vesicatoria*, or blistering fly. These insects are chiefly brought from Astracan and Sicily: they should be free from mould and dust, of a peculiar but not very strong or nauseous odour, and of a brilliant golden green colour. These flies furnish us with the only ready and certain means of raising an effective blister upon the skin, for which purpose they are reduced to powder, mixed with ointment or lard, and spread thinly upon a piece of leather, which is then applied to the part affected. Their operation is very different in different habits and constitutions: sometimes they produce much local pain and inconvenience, and great general excitement and irritation of the urinary organs; at others they are comparatively quiet in their action; and the blister being applied at bed-time, is found in the morning to have raised the cuticle with a large quantity of serous fluid underneath it, and the patient has scarcely been aware of its agency. The object of applying a blister is generally to transfer internal inflammatory action to the surface; and in deep-seated inflammations, and painful affections of the viscera and larger joints and muscles, they are often astonishingly effective. But blisters should not be incautiously applied: they sometimes produce troublesome sores, and are followed by erisipelatous inflammation. Care should also be taken to confine then, by a margin of adhesive plaster or other means, to the part upon which they are intended to operate, as they sometimes are displaced, and give rise to awkward accidents. When cantharides are taken internally, they are violently stimulant to the urinary and generative organs.

CA'NTHUS. (Lat.) The corner of the eye, where the upper and under eyelids meet.

CANTILE'VER. (Probably from canterii labrum, *the lip of a rafter.*) In Architecture, a piece of wood framed into the front or side of a house, and projecting from it, to sustain the eaves and mouldings over them.

CA'NTO. *See* SOPRANO.

CA'NTO-FE'RMO. (Ital. *firm song.*) In Music, the subject song. Every part that is the subject of counterpoint, whether plain or figured, is called by the Italians *canto fermo.*

CA'NTON. In Heraldry, an ordinary formed either at the dexter or sinister chief of the escutcheon, by two lines meeting at right angles, proceeding from the top or sides of the shield. By the word canton is always understood a canton dexter, unless otherwise expressed.

CANTON. (Gr. κανθος, *an angle;* or Lat. centum, *a hundred.*) In Geography, originally a quarter of a city regarded as separated or detached from the rest; but applied chiefly at present to the twenty-two districts of which Switzerland is composed, and which, though forming a confederate union like the United States of America, are governed each by a separate judicature and particular laws.

CANTO'NMENT. In the art Military, that distinct situation which soldiers occupy when quartered in different parts of a town, for want of barracks or caserns to contain them.

CA'NVAS. (Ital.) A very clear unbleached cloth of hemp or flax, woven regularly in little squares, chiefly used to make sails for shipping. Besides serving for various domestic purposes, such as for the ground of tapestry work, canvas forms the cloth on which painters usually draw their pictures.

CANZO'NE. (Latin, Provençal, and Italian, cantare, *to sing.*) A kind of lyric poem. Adopted, with some alteration, from the poetry of the Troubadours, it found its way into Italy in the thirteenth century. It is divided, like the Greek strophic ode, into stanzas, in which the number and place of rhymes and metre of verses respectively correspond. The last stanza, commonly shorter than the others (the epodus of the ode), is called *congedo*, or *ripressa* (in old French *l'envoy*), and consisted, generally, of a valedictory address to the canzon itself. This form of poetry was adapted by Petrarch to the expression of

many different veins of thought — sonorous, elevated, and heroic. The Pindaric ode, somewhat more regular than the canzon, was introduced by Chiabrera. The canzonet was a sort of canzon in short verses, a favourite form with the poets of the fifteenth century.

CANZONE'TTA. (Dimin. of canzone.) In Music, a short song. The Neapolitan canzonet has two strains, each of which is, like the French vaudeville, sung twice over. The Sicilian canzonet is n a species of jig-time, with six or twelve quavers in the bar. Sometimes both are rondeaus, and repeat the first strain for an ending.

CAOU'TCHOUC. This curious substance is the inspissated juice or sap of several plants: the principal supplies are from South America, and are derived from the *Siphonia elastica* (Hevea caoutchouc), and probably from other Euphorbiaceous plants. It is often termed *gum elastic* and *Indian rubber*. Its general properties and uses are well known. Among its more recent applications are those of elastic wove fabrics, formed of caoutchouc stretched into threads and covered with cotton; and various water-proof clothing, which is made by interposing a layer of caoutchouc between two folds of the cloth, and then forcibly uniting them by pressure. For this purpose the caoutchouc is dissolved by coal naphtha, and in that state brushed over the surfaces which are to be united.

Caoutchouc is a compound of carbon and hydrogen; when heated it fuses, and afterwards remains viscid; when subjected to destructive distillation at a high temperature, it yields four fifths of its weight of a highly inflammable and very light volatile oily liquid (hydrocarbon), which has been called *caoutchoucine*, and which is a good solvent of the unaltered caoutchouc. Washed sulphuric ether dissolves caoutchouc, and it is also soluble in several essential oils; but of these latter solutions the greater number leave it in a sticky state on evaporation.

CAPA'CITY FOR HEAT. Experiment shows that different quantities of heat are required to raise different bodies to the same temperature, and those substances which require the largest quantity of heat to be raised to a given temperature are said to have the greatest *capacity for heat*. *See* Specific Heat.

CAPE. (Lat. caput, *a head*.) In Geography, is the term used to indicate the extreme point of a promontory, or of that portion of land which juts out into the sea beyond the general line of the coast; as Cape Taenarus or Matapan, the most southern part of Europe; the Cape of Good Hope, the most southern part of Africa; Cape Horn, the southern extremity of America, &c. On rocky and much indented coasts capes generally terminate in acute angles, whence they are sometimes denominated *points*; and if the portion of the land which projects is small or not high, the appellation *ness* in England, and in Scotland that of *mull*, is assigned to it, as Sheerness, the Mull of Galloway.

CAPE'LLA. A star of the first magnitude in the left shoulder of Auriga.

CA'PERS. The buds or unexpanded flowers of the *Capparis spinosa*, in common use as a pickle.

CA'PIAS AD RESPONDENDUM. In Law, a writ for the commencement of personal actions to arrest a party who is at large or already in custody of a sheriff.

CA'PIAS AD SA'TISFA'CIE'NDUM. Shortly called *ca. sa.*) In Law, a judicial writ of execution which issues out on the record of a judgment, where there is a recovery in the courts of Westminster, of debt, damages, &c. By this writ the sheriff is commanded to take the body of the defendant in execution. This is the highest execution which can be had against a defendant, and no other can be afterwards had against his lands or goods, unless he die in custody.

CAPI'BARA. The largest known Rodent quadruped. It is of aquatic habits, and frequents the rivers of South America. It is the type of the genus *Hydrochærus*, signifying "water-hog," by which name it is sometimes known.

CAPILLA'IRE. Simple syrup flavoured with orange flowers, or orange flower water, generally goes under this name, which is derived from the mucilaginous syrup directed in old Pharmacopœias to be made of the *Adiantum capillus veneris*.

CAPI'LLAMENTUM. (Lat. capillus, *a hair*.) An old name of the filament of a flower. *See* Filament.

CAPI'LLARY. Long and slender, like a hair.

CAPI'LLARY A'CTION. (Lat. capillus, *a hair*.) When a very narrow glass tube, open at both ends, is inserted in a vessel containing water, the water immediately rises in the tube, and remains suspended at some height above its level in the vessel. If the same tube is plunged into mercury, the mercury in the tube stands at a lower level than in the vessel. These effects are most sonspicuous when the width of the bore of the tube is so small as to resemble a hair; whence the cause of the phenomena has been termed *capillary action*, from the Latin *capillus*, which signifies a hair.

The operation of the same forces which cause the elevation of water and depression of mercury in glass tubes, gives rise to a multitude of other phenomena with which every one is familiar. If a piece of sugar, or sponge, or blotting paper, is brought into contact with water at one extremity, the fluid immediately passes through it and moistens its whole substance. A mass of wetted thread or cloth, hanging over the edge of a basin from the water within it, will empty it as a siphon would. The rise of the oil in the wick of a lamp, of the sap in trees, the functions of the excretory vascular system in plants and animals, depend on the same causes. Capillary action is, in short, only an instance of the operation of that species of attraction which is exerted among the elementary particles of matter within very small or insensible distances, which is called *molecular attraction*, and which gives rise to some of the most important phenomena of the physical world; such as the vibrations of solid bodies, the refraction of light, and chemical actions of all kinds.

The phenomenon of the elevation of water in narrow tubes began to attract the attention of experimental philosophers about the beginning of the last century; but neither the method of calculating the effects of the forces exerted among the elementary molecules of matter, nor their mode of operation, was then understood, and consequently no satisfactory theory was proposed. Two facts, however, of considerable importance were established by Hauksbee. The first is, that the ascent of the liquid is quite independent of the thickness of the tube; and the second, that if two rectangular plates of glass having their edges joined in a vertical line, and forming a very acute angle with each other, are dipped into water, the fluid which rises between them takes the form of the equilateral hyperbola. On considering the phenomenon attentively, it was easy to see that as the height of the fluid between the plates at any point in the curve was inversely proportional to the distance of the plates at that point, it must follow that in capillary tubes the ascent would be inversely proportional to the diameter of the tube. The theory of the phenomenon, however, still remained unexplained.

Dr. Jurin ascribed the ascent of the liquid to the attraction of the ring of the tube immediately above it. But this was merely a vague explanation, and is now known to be altogether erroneous. Clairaut, in his celebrated work on the Figure of the Earth, was the first who analyzed exactly the different forces which concur in elevating the liquid in a capillary tube, and reduced the phenomena to the ordinary laws of the equilibrium of fluids. Some of his suppositions respecting the nature of the forces in action were erroneous; for example, he supposed the attraction of the internal surface of the tube on the liquid to be exerted not only at a sensible distance, but to extend even to the diameter. He failed to prove from theory that the ascent must be inversely proportional to the diameter of the tube; but he showed that several hypotheses might be made with respect to the law of attraction from which that law of ascent would follow; and he demonstrated a very remarkable result, namely, that if the attraction which the particles of the tube exercise on the fluid and the attraction which the particles of the fluid exercise on each other follow the same law, and differ from each other only in intensity, the fluid will rise in the tube when the first of these attractions exceeds half the second. The error of Dr. Jurin's hypothesis was first clearly pointed out by Professor Leslie, in a paper inserted in the *Philosophical Magazine*, in 1802. Mr. Leslie's argument was shortly this: If the ring of the tube immediately above the liquid in a capillary tube attract it upwards, how does it happen that the ring immediately below the surface does not attract it downwards, in which case the forces would be balanced, and there would be no elevation? The fact is, that as the action of the molecules of the tube is confined within very narrow limits, its direction must be at right angles to the sides of the tube. Nor is it difficult to conceive how a lateral action may yet cause a perpendicular ascent. It is a fundamental property of fluids, that any force impressed in one direction is propagated equally in every direction; the tendency of the fluid, therefore, to approach the glass will occasion it to spread over the internal cavity of the tube, and consequently to mount upwards. Mr. Leslie's explanation, though correct in principle, served in no way to advance the theory; indeed little notice appears to have been taken of it till its importance was pointed out by Mr. Ivory. Another important fact was discovered by Dr. Young, who showed, in a paper on the *Cohesion of Fluids*, in the *Phil. Trans.* for 1805, that the angle made by the surface of the fluid with the sides of the tube is invariable, the fluid and the materials of the tube remaining the same, and being supposed homogeneous.

But a complete exposition of the theory of capillary phenomena was reserved for Laplace. In two Supplements to the *Mécanique Céleste*, published in 1806 and 1807, Laplace, assuming the force of molecular action to extend only to insensible or imperceptible distances, determined the separate influences of the cohesive attraction of the molecules of the fluid to each other, and the adhesive

force with which they cling to the tube. This analysis of the forces by which the capillary phenomena are produced conducted him to an equation in which the whole theory is included. It consisted of two parts: the first belonging to those points of the surface of the fluid whose distance from the sides of the tube is greater than the radius of the sphere of molecular action; and the other belonging to those points of the surface which are in immediate contact with the sides of the tube, or at least within the sphere of the action of its molecules. The first term is general, and the same for all surfaces; the other varies with the curvature in each particular case. Mr. Ivory afterwards showed that of the two quantities which enter into the formula of Laplace, the one denotes the direct pressure caused by the attraction of a fluid mass bounded by a plane; and the other the derivative force acting laterally, which is a necessary consequence of the direct pressure. (*Ency.Brit.* art. "Capillary Action.")

The latest and most important work on capillary action is by Poisson, *Nouvelle Théorie de l'Action Capillaire*, 1831. Its object was to correct the theory of Laplace by supplying an important omission in the physical data, namely, the rapid diminution of density which takes place near the free surface of the fluid, and near the sides of the tube. Now this circumstance, though it had been entirely overlooked by all former inquirers, is not only essential to the right investigation of the effects of capillary action, but it is demonstrated by Poisson that if there was no diminution of density near the superficial parts of the liquid, the surface would remain plane and horizontal, and there would neither be elevation nor depression in the capillary tube. The molecular forces, therefore, which produce the capillary phenomena, are modified not only by the curvature of the surface, according to the previous theory, but also by the particular state of liquids at their surfaces.

The power of supporting the fluid column depends entirely on the width of the tube at its upper extremity. If the tube bulge out below, the water will not rise in it spontaneously; but if plunged into a basin till the water reaches the capillary part, and then lifted up, the water will remain suspended at exactly the same height as in a tube having the same capillary bore throughout. The lower and wide part of the vessel may consist of metal, or any other substance, different from glass. It is sufficient that the cavity terminate above in a capillary glass tube.

The phenomenon of the depression of mercury in capillary tubes may be considered as the inverse of that of the elevation of water. The molecules of water have a greater attraction for glass than for each other; those of mercury, on the contrary, attract each other more powerfully than they are attracted by glass. If a drop of mercury, adhering to the edge of a plate of glass, is presented to a mass of the same fluid, it immediately leaves the glass and unites with the mass. When a plate of glass is plunged into mercury, the mercury is depressed, and forms a convex surface on both sides of the plate. In a glass tube the surface of mercury is always convex, provided the inside of the tube be perfectly clean, and the mercury free from impurities. All these phenomena clearly indicate the excess of the mutual attraction of the particles of mercury above their adhesion to the sides of the glass.

From some experiments made by *Casbois* at Metz, it appeared to result, that mercury purified with great care forms a concave surface in the interior of a glass tube, and consequently rises above the level, like an aqueous fluid. It is now generally admitted, however, that these experiments were fallacious, in consequence of the inner surface of the tube having been lined with a slight, and perhaps imperceptible, oxydation produced by the boiling of the mercury. In preparing barometers, it has been the custom to boil the mercury in the tube; when this operation is performed, great caution is requisite to prevent the oxydation from taking place.

The form of the surface of the fluid in the tube indicates the relation of the cohesive force of its particles to their attraction for the tube. The attraction of water to glass is superior to half the cohesion of the aqueous particles to one another; consequently water within a capillary tube assumes a concave surface, and rises. Mercury, on the other hand, assumes a convex surface, and is depressed; because its molecules attract one another with a force more than double that with which they adhere to glass. The radius of curvature of the bounding surface at the middle point is proportional to the width of the tube. It is stated by Professor Leslie as the result of his experiments, that the depression of mercury in capillary tubes may be estimated at unity divided by 68 times the diameter expressed in inches. Hence if the width of the bore is one fourth of an inch, the depression of the mercury is one seventeenth of an inch. On this account it is necessary, in accurate barometric observations, to apply a correction for capillary action, which is less in proportion as the diameter of the tube is greater. The best treatises on this subject have already been referred to; viz. that of Laplace, in the *Mécanique Céleste*, tome iv.; of Mr. Ivory, in the *Encyclopédia Britannica;* and of Poisson, *Nouvelle Théorie de l'Action Capillaire.*

CAPI'LLARY VESSELS. (Lat. capillus, *a hair.*) Anatomists give this term to the minutest ramifications of the arteries and other vessels.

CAPILLI'TUM. (Lat. capillus, *a hair.*) A kind of purse or net in which the spores of Trichia and similar fungi are retained.

CA'PITAL. (Lat. caput, *a head.*) In Architecture, the head or uppermost member of any part of a building; but it is generally applied in a restricted sense to that of a column or pilaster of the several orders, as in the figures here given, in which it will be seen that the Tuscan capital (No. 1.) consists of an abacus or square shelf at the top, and thereunder an ovolo or quarter round, and under that a neck terminated by an astragal or fillet, which latter is

1 2 3 4 5

always considered as part of the column itself. The Roman Doric capital (No. 2.) here given has an abacus, ovolo, and neck like the last; and also in addition three annulets under the ovolo, and a cyma or ogee with its fillet over the abacus. The Grecian Doric, however, has only a square abacus, ovolo, and small fillets. The Ionic (No. 3.) capital consists of three leading parts: an abacus, composed of an ogee and fillet; a rind, which forms the scrolls; and an ovolo and astragal at the lower part. The Corinthian and Composite capitals (Nos. 4. and 5.) consist of an abacus (*see* Abacus) of peculiar form, and are decorated with leaves.

Ca'pital. In Political Economy, that portion of the produce of labour saved from immediate consumption which is employed to maintain productive labourers, or to facilitate production. (*See* Political Economy.) In Commerce, and as applied to individuals, capital is understood to mean the sum of money which a merchant embarks in any undertaking, or which he contributes to the common stock of a partnership.

CAPITA'TION. (Lat. caput, *head.*) A tax imposed on the population by the head; *e. g.* on every one, or every male, every one above a certain age, &c. (*See* Poll-Tax.) In France, the ancient capitation is now replaced by personal and other direct contributions.

CA'PITE. In Law, tenure *in capite* (Ang. *in chief*) signifies in the language of feudal law a direct holding of the king, the ultimate sovereign, without the intervention of any mesne lord. In England, tenants in capite were either by knight-service or socage; which were converted into common socage by the act 12 Ch. II. c. 24., abolishing feudal tenures.

CA'PITE CENSI. In Roman Antiquity, the lowest rank of Roman citizens; so called because they were rather counted by their *heads* than by their estates. (*Aul. Gell.* lib. vii. cap. 13.)

CAPI'TULA'TION. In its original sense, a writing drawn up in several *capitula* or heads. In the language of Military Law, the articles of surrender, when a garrison or other force surrenders to an enemy on terms, and not at discretion. In Ecclesiastical History, articles sworn by bishops and other prelates on admission to their dignities were styled capitulations. So also was the oath tendered first to Charles V., and then to the emperors of Germany who succeeded him, by the electors, termed the election capitulation (wahl capitulation).

CA'PNOMA'NCY. (Gr. *καπνος, smoke; μαντεια, prophecy.*) Divination by smoke was practised among the ancients, both by throwing on the fire seed of poppy and other herbs, and observing the figures which might be fancied in the smoke; and by observing the smoke of sacrifices.

CA'PNOMOR. (Gr. *καπνος, smoke,* and *μοιρα, part.*) An oily substance of a pungent and rather agreeable odour obtained from the tar of wood.

CAPONNIE'RE. In Fortification, a passage leading from one work to another, protected on each side by a wall or parapet, generally of earth, sloping to the bottom of the ditch. When a passage is thus protected on one side only, it is called a demi-caponniere.

CAPPA'RIDA'CEÆ. (Capparis, one of the genera.) A natural order of Exogenous plants, consisting of annuals, perennials, bushes, and trees, inhabiting the warmer parts of the world. They have all a powerful pungent or even acrid taste, and have been in some cases used as substitutes for the common mustard; in others they have proved severe poisons. In general their flowers are very beautiful, on account not only of their size, but of their long silken stamens, which are often gaily coloured. The common caper-bush, a native of rocky places in the North of Europe, is a species of the genus *Capparis*, and

yields the flower-buds which, pickled in vinegar, are sold in the shops as an agreeable sauce for various dishes.

CAPRE'LLA. A genus of Crustaceous animals belonging to the order *Læmodipoda*, found commonly on sea-weed. Montague, who describes a species of this genus in the seventh volume of the *Linnæan Transactions*, says the female differs in possessing several plates or valves beneath the body, situated between the two pairs of fins, the use of which is to carry and protect its eggs or young; at which time they extend very considerably, and form a kind of pouch distended with ova, fifteen or twenty of which are easily distinguished between the transparent plates. In this part a very strong pulsation is visible. While examining a female under a water-microscope, the author was surprised to observe not less than ten young ones crawl from the abdominal pouch of the parent, all perfectly formed, and moving with considerable agility over the body of the mother, holding fast by their hind claws and erecting their heads and arms. The characters of the genus, or rather family (*Caprellidæ*), are, body of narrow linear form; eyes composite, and placed behind; legs long and slender, and variable in number, the last joint of the second pair being often toothed on the under side.

CAPRE'OLUS. (The tendril of a vine.) The old botanical name of the tendril of a plant; the term *cirrhus* is now preferred.

CAPRI'CCIO. (Ital. *whim, fancy.*) In Music, a term applied to certain pieces, wherein the composer gives way to his fancy, without confining himself to particular measures or keys; called also *Fantasia*.

CA'PRICO'RNS. (Lat. capricornus.) The name of one of the three divisions of Tetramerous beetles; including those which have the antennæ filiform or setaceous, and generally exceeding the length of the body; eyes lunate, and enclosing the base of the antennæ; jaws very robust, with short palpi; thorax often spined at the sides; the three basal joints of the tarsi dilated, and cushioned on the under surface; the third deeply cleft at the extremity, and receiving the minute ball at the base of the slender and long terminal joint. This division comprehends four great families,—*Prionidæ*, *Cerambycidæ*, *Lamiidæ*, and *Lepturidæ;* and corresponds very nearly with the Linnæan genera *Cerambyx*, *Necydalis*, and *Leptura*. The offices of the capricorn beetles in the economy of nature is to restrain the excessive multiplication of vegetable species in the warmer climates of the globe. The larvæ reside within the wood or beneath the bark of trees.

CA'PRICO'RNUS. (Lat.) *The Wild Goat.* The tenth sign of the Zodiac, which the sun enters about the 21st of December, at the winter solstice. The parallel circle passing through the first point of this sign is called the *Tropic of Capricorn.*

CA'PRIFO'LIA'CEÆ. (Caprifolium, one of the genera.) A rather large natural order of plants, consisting of twining and erect shrubs, and herbaceous or woody plants, and even of trees, with simple or pinnated leaves, and flowers of most dissimilar forms, but all monopetalous. The most common plants belonging to this order are the woodbine, the St. Peter's wort, the Tartarian and fly honeysuckle, the numerous species of viburnum, and the elder-tree. These all agree with the natural order *Cinchonaceæ* in most respects, except the absence of stipules at the base of the leaves.

CAPRIFO'LIUM. (Lat. capra, *a goat,* and folium, *a leaf.*) Is the genus to which the wild honeysuckle (*C. periclymenum*) belongs. It consists of twining shrubs inhabiting the northern hemisphere exclusively, and in most cases having long tubular flowers of singular sweetness. Many species are known to botanists, the most interesting of which are those from the north of India, China, and Japan, the fragrance of which is superior to that of all others; of these *C. flexuosum*, now common in gardens, is the best.

CA'PROIC ACID. (Lat. capra, *a goat.*) One of the acids formed during the saponification of butter; it has a rank goat-like odour.

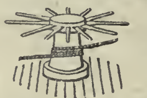
CA'PROMYS. (Gr. καπρος, *a boar*, and μυς, *a mouse.*) The name of a genus of Rodent Mammalia, exclusively confined to the island of Cuba, where they go by the name of Houtias.

They have four molars on each side of each jaw, in which the enamel is so folded as to form three angles on the outer margin and one on the inner, in the upper teeth; the reverse in the lower teeth. The liver is remarkably subdivided in the rodents of this genus.

CA'PROS. (Gr. καπρος, *a boar.*) A name applied by Lacipede to a subgenus of Acanthopterygious fishes, which he separated from the dories (*Zeus*), and of which the boar fish (*Zeus aper*, Linn.) may be regarded as the type. A specimen of this fish has been taken at Mount's Bay, and another near Bridgewater, but is rare as a British species.

CA'PSICUM. (Gr. καπτω, *I bite;* from its pungency.) The berry or seed-vessel of different species of capsicum. The larger pods of the *Capsicum annuum*, and the smaller ones of the *C. baccatum* or *bird pepper*, when powdered, form the *Kyan pepper* of commerce, so well known as a powerful condiment, and often useful as a stimulating medicine. Kyan pepper is often grossly adulterated with common salt, and occasionally red lead and earthy powders are said to be added to it: it often has a disagreeable rancid odour, owing to its being sprinkled with oil to prevent its dust affecting those who powder and sift it.

CA'PSTAN, sometimes called CAPSTERN. (Fr. cabestan.) A strong massive piece of timber, in the form of a cylinder or truncated cone, round which a rope is coiled; and being turned by means of bars or levers, it affords an advantageous mode of applying power to overcome an obstacle. The capstan is chiefly employed in ships, where it is used for weighing anchors, hoisting sails, &c. It is generally placed vertically, the lower end being let down through the deck of the ship, and the levers inserted in holes in the head or top; so that the force of the men can be exerted continuously, and that there may be no necessity for removing the levers from one hole to another, as is the case when it is placed horizontally. The power of the capstan may be greatly increased by adapting an arrangement of wheel work to it — an improvement which has been adopted for several years past in the royal navy.



CA'PSULA. (Dim. of capsa, *a box.*) This word is generally applied by botanists to all dry fruits which are dehiscent, whether they are many-seeded or few-seeded, simple or compound; and in such cases some expletive is added to indicate the particular nature of the fruit. Thus *Capsula circumscissa* is cut round by a circular line dividing it into two parts; *C. siliquiformis* is long and taper, like the pod of a mustard-plant; *C. baccata* is when the pericarp is succulent; *C. tricoccea*, when a dry capsule bursts into three separate closed pieces. Sometimes, for special carpological purposes, the word capsula is limited in its application to such dry compound fruits as open by valves, and have an indefinite number of seeds; as in *Digitalis*, *Scrophularia*, the common lilac, &c.

CA'PSULE. In Chemistry, a small shallow evaporating vessel or dish.

CA'PTAIN. In the Army, the commander of a troop of cavalry or of a company of infantry. The price of a captain's commission is different in the different branches of the British service: in the life guards, for instance, it is 3,500*l.*; in the dragoons 3,225*l.*; in the foot guards with the rank of lieut.-colonel, 4800*l.*; in the infantry 1,800*l.* The full pay of a captain in the life and foot guards is 15*s.* a day, in horse regiments 14*s.* 7*d.*, and in the infantry 11*s.* 7*d.*

CA'PTAIN. In the Royal Navy, is the title of the officer commanding a ship of a certain size. The title of post captain, which was the proper rank of captain, and answered to colonel in the army, has been for some time in disuse. The captain is next in rank above the commander: he rises by regular succession to the rank of admiral; under the condition, however, that he must at some time have commanded a ship of the line.

The heads of small parties or gangs of men in certain stations of the ship are also called captains; as of the forecastle, the tops, &c. The pay of a captain in the navy varies with the rate of the ship, from 61*l.* 7*s.* per month for a first-rate, to 26*l.* 17*s.* for a sixth-rate.

CA'PTION. (Lat. capio, *I take.*) In Law, a certificate signed by commissioners, to testify their execution of any commission in law or equity. Also, the act of taking a man into arrest. The caption of an indictment is the designation of the style of the court before which the jurors make their presentment.

CAPTI'VITY. In Sacred History, a punishment which God inflicted upon the Jews for their vices and infidelity. The first captivity was that of Egypt, from which the Israelites were delivered by Moses; then followed six captivities during the government of the judges: but the greatest and most remarkable were those of Judah and Israel, which happened under the kings of these different kingdoms.

CA'PUCHINS. In Ecclesiastical History. *See* FRANCISCANS.

CA'PUT MO'RTUUM. The inert residue of the distillation and sublimation of different substances. When sulphate of iron, for instance, or green vitriol, is distilled at a red heat it leaves a residue of red oxide of iron, which the old chemists called *caput mortuum vitrioli.* These residuary products were represented in alchemical writings by the symbol of a death's head and cross bones.

CAR. (Lat. carrus, *a cart.*) Any rude cart. The Irish car is a one-horse cart, with very low broad wheels, used for carting out manure and carting home grain in the case of soft peaty soils. The Irish jaunting car is a kind of one-horse chaise, commonly without springs, in

which the people sit back to back, and with their faces looking sideways.

CARABI'DÆ. (Lat. carabus.) A family of Pentamerous beetles, characterized by having a bilobed upper lip, smooth jaws (*maxillæ*), an entire tooth in the centre of the notch of the mentum or chin-process, and dilated tarsi in the males. The majority of the British species have the elytra soldered together. The *Carabidæ* generally defend themselves by discharging from the extremity of the body an acrid fluid, and emit a fetid odour. They are amongst the most ravenous of beetles, and prey on other insects, for which they lurk beneath stones, the bark of trees, &c.

CA'RABINE. (It. carabino.) Called also Petronel. A fire-arm used by cavalry, smaller in the bore and shorter in the barrel than a musket. The soldiers who use this species of arms are called Carabineers.

CARAGA'NA. (Carachana, the Mogul name.) A genus of pretty hardy shrubs, inhabiting the Russian dominions in Asia. *C. sibirica*, *attagana*, and *chamlagu* are common in the shrubberies of this country, where they flower in the months of June and July. *C. jubata* is a singular scrubby plant, with the branches closely covered by the leafy, spiny, ragged petioles.

CARA'NNA. A resin brought from South America, of an aromatic odour; formerly used in plasters.

CA'RANX. (Derivation unknown.) A genus of spiny-finned fishes, belonging to the *Scomberidæ* or mackerel family; but differing from the true mackerel in having a series of scales, with ridges or keels in the middle, ranged along the lateral line. From this resemblance they are commonly termed "bastard mackerel."

CARA'SSÆ. The bony vault which protects the upper part of the body of the Chelonians, or tortoises and turtles, and which results from the union by suture of the dilated and flattened parts of the vertebræ and ribs. The analogous part of the body of the crab is also called carassæ; but this is not composed of corresponding parts to those of the tortoise, but of a calcified integument.

CA'RAT. "The fruit of the tree called Kuara is a red bean, which seems in the earliest times to have been used for a weight of gold. This bean is called *carat*. (*Bruce's Travels*.) Morin derives the word from the Arab *kyrat*, a weight; which he thinks is from the Greek *κερατιον*, a small weight." (*Todd's Johnson*.) A carat is a weight of 4 grains, used in weighing diamonds. The term carat is also used in reference to the fineness of gold; in expressing which the mass spoken of is supposed to weigh 24 carats, of 12 grains each; and the pure gold is called *fine*. Thus, if gold be said to be 22 carats fine (or standard), it is implied that 22-24ths are pure gold, and 2-24ths alloy. In the process of assaying gold, the real quantity taken is very small, generally from 6 to 12 grains; and this is termed the *assay pound*. It is subdivided into 24 carats, and each carat into 4 assay grains, and each grain into quarters; so that there are 384 separate reports for gold. When the gold assay pound is only 6 grains, the quarter assay grain only weighs 1-64th of a grain. This will give an idea of the accuracy required in the weights and scales used for such delicate operations. See ALLOY and ASSAY.

CA'RAVAN. (Pers. cârvân, *a trader*.) A company of merchants, travellers, or pilgrims, who associate together in many parts of Asia and Africa, that they may travel with greater security through deserts and other places infested with robbers or exposed to other dangers. The commercial intercourse of Eastern and African nations has from the remotest ages been chiefly carried on by means of caravans, as the governments that have sprung up in those continents have seldom been able, even if they had had the will, to render travelling safe or practicable for individuals. Since the establishment of the Mohammedan faith religious motives, conspiring with those of a less exalted character, have tended to augment the intercourse between different parts of the Eastern world, and to increase the number and magnitude of the caravans. Mohammed, as is well known, enjoined all his followers to visit Mecca once in their lifetime; and in obedience to a command so solemnly enjoined and sedulously inculcated, large caravans assemble for this purpose in every country where the Mohammedan faith is established. There are four regular caravans which proceed annually to Mecca; the first from Damascus, composed of pilgrims, travellers, and merchants, from Europe and Asia; the second from Cairo, for the Mohammedans of Barbary; the third from Zibith, near the mouth of the Red Sea, where those of Arabia and India meet; the fourth from Babylon, where the Persians assemble. Every caravan is under the command of a chief or aga (caravanbachi), who has frequently under him such a number of troops or forces as is deemed sufficient for its defence. When it is practicable they encamp near wells or rivulets, and observe a regular discipline. Camels are almost uniformly used as a means of conveyance, in preference to the horse or any other animal, on account of their wonderful patience of fatigue, and their peculiarity of structure, which so admirably fits them for travelling through desert wastes. (*See* CAMEL.) For further details on the subject of caravans the reader may consult *M'Culloch's Commercial Dictionary*, and the authorities there referred to.

CARAVA'NSERA. A large public building, or inn, appropriated for the reception and lodgment of caravans in the desert. Though serving in lieu of inns, there is this essential difference between them, that the traveller finds nothing in the caravansera for the use either of himself or his cattle, but must carry all his provisions and necessaries with him. Caravanseras are also numerous in cities, where they serve not only as inns, but as shops, warehouses, and even exchanges.

CA'RAWAYS. The fruit or seed of the *Carum carui*, an indigenous umbelliferous plant. English caraways are more plump and aromatic than the Dutch or foreign, which are apt to be mouldy and of little flavour. They yield about 3 per cent. of essential oil when carefully distilled with water. They are a good addition to purgative and other remedies to prevent griping and flatulency; but their chief consumption is among gingerbread bakers, confectioners, and pastrycooks.

CARBAZO'TIC ACID. A crystallizable acid and bitter substance, composed of carbon, azote, and oxygen; obtained by the action of nitric acid on indigo and some other vegetable and animal substances. It is the bitter principle of Welter.

CA'RBON. (Lat. carbo.) This term is used in chemistry to signify the pure combustible base of the varieties of charcoal and other carbonaceous matters; the diamond is pure carbon in a crystalline form. Carbon is an elementary substance, which combines with oxygen in two proportions, forming *carbonic acid* and *carbonic oxide*.

CA'RBONATES. Salts containing carbonic acid. They are recognized by the effervescence which is excited when they are put into dilute muriatic acid. *Carbonate of lime* is one of the most important of these compounds, forming the varieties of marble, limestone, calcareous spar, chalk, &c. Carbonate of lime consists of

Lime	1 atom	=	28	56
Carbonic acid	1	=	22	44
	1		50	100

Carbonate of potash and carbonate of soda are also important salts. (*See* POTASH, SODA.) *Carbonate of ammonia* is used in medicine; it is a white pungent salt, commonly known under the name of *smelling salt*. *Spirit of hartshorn* is a solution of impure carbonate of ammonia, obtained by distilling bone or horn.

CARBO'NIC ACID. This important compound is obtained when any form of carbon, such as the diamond or pure charcoal, is burned in oxygen gas. It consists of 6 carbon + 16 oxygen = 22 carbonic acid; or of

Carbon	1 atom	6	27·27
Oxygen	2	16	72·73
	1	22	100·00

100 cubical inches of carbonic acid gas weigh 47·3 grains. Under a pressure of 36 atmospheres, at the temperature of 32°, it becomes liquid; and when the pressure which retains it in the liquid state is removed, the rapidity of the evaporation, and the sudden and enormous expansion of the vapour, are such as to produce a degree of cold under which the acid solidifies, forming a white concrete substance possessed of very extraordinary properties. Mr. Faraday was the first who liquefied carbonic acid, but it was first described as a solid by M. Thilourier.

At common temperatures and pressures water absorbs its own volume of carbonic acid; under a pressure of 2 atmospheres it dissolves twice its volume, and so on. Carbonic acid imparts briskness and a slightly pungent and sour taste to water thus impregnated with it; it also confers the effervescent quality upon many mineral springs. Carbonic acid is recognized by its rendering lime-water turbid. It extinguishes flame and suffocates animals; hence the miners call it *choke damp*. Carbonic acid is contained in marble, chalk, and all the varieties of limestone, from which it is extracted by strong heat, as in the process of *burning* lime; or by the action of stronger acids, in which case the carbonic acid escapes with *effervescence*. Mountains of limestone, therefore, are great natural repositories of carbonic acid. This gas is also produced during the respiration of animals, and is evolved in the process of fermentation.

CARBO'NIC OXIDE. A gas composed of

Carbon	1 atom	6	42·8
Oxygen	1	8	57·2
	4	14	100·0

100 cubical inches weigh 30·2 grains. It is fatal to animals, and extinguishes flame; but it burns in contact with air, and forms carbonic acid. It is obtained by passing carbonic acid over red-hot charcoal, or by heating a

mixture of chalk or pounded marble and iron or zinc filings to redness. It is not absorbed by water.

CA'RBONI'FEROUS. (Lat. carbo, *coal*, and fero, *I bear.*) A geological term, generally applied to beds or strata containing coal.

CA'RBOY. A large globular bottle of green glass protected by basket work. Carboys are seldom used, except for containing certain acids and other highly corrosive liquids likely to act upon stone-ware. A carboy of oil of vitriol usually contains about 160 lbs. of that acid, or 12 gallons of water.

CARBU'NCLE. The ancient name of a gem, probably corresponding with our precious *garnet*.

CARBU'NCLE. A hard circumscribed inflammatory tumour, which generally arises on the neck or back, and soon forms a fetid discharge, and acquires a tendency to gangrene. It is a kind of malignant boil, spreading under the skin, and producing a morbid inflammatory action of the surrounding parts. Poultices and free incisions to let out the matter, and afterwards emollient fomentations, are the most effective remedies. This disease is called *anthrax*, from the Greek, signifying a burning coal; of which *carbunculus*, from *carbo*, is the Latin diminutive.

CA'RBURETS. In Chemistry, the generic term for compounds of carbon with the simple combustibles.

CA'RBURET OF SULPHUR. A liquid compound of carbon and sulphur, obtained by passing the vapour of sulphur over red-hot charcoal. It was formerly termed *alcohol of sulphur*. It forms compounds, which have been termed *carbo-sulphurets*.

CA'RBURETTED HY'DROGEN. Under this term chemists describe two gaseous compounds of carbon and hydrogen; the one they call *light hydrocarbonate*, the other *olefiant gas*.

Light carburetted hydrogen is evolved abundantly in some coal mines, where it is known under the name of *fire damp*, and is the cause of those tremendous explosions which were so frequent before the invention of the safety lamp by Sir H. Davy: it is also evolved by the mud at the bottom of stagnant waters, where it results from the decay of vegetable matter. This gas is much lighter than atmospheric air, 100 cubical inches weighing between 17 and 18 grains. It burns with a yellow flame, is inodorous, and not absorbed by water. It consists of 6 carbon + 2 hydrogen. When mixed with three volumes of oxygen, or with eight or ten of common air, it explodes with great violence when inflamed, and produces water and carbonic acid.

Olefiant gas received its name from its property of forming, when mixed with chlorine, a liquid of an oily appearance. It is obtained by distilling a mixture of alcohol with twice its bulk of sulphuric acid, and may be collected over water; which, however, absorbs about one eighth of its volume of the gas. It has a slightly ethereal odour; it extinguishes flame; is unrespirable; burns with a dense white light; and when mixed with three or four volumes of oxygen or ten or twelve of air, it detonates on the approach of flame with great violence. It is nearly of the same specific gravity as atmospheric air; and from the quantity of oxygen required to convert its elements into carbonic acid and water, it is shown to consist of two atoms of carbon and two of hydrogen, its equivalent being 14; or of one volume of carbon vapour and two volumes of hydrogen, so condensed as to form one volume of olefiant gas.

CA'RCASS. In Artillery, a hollow case formed of ribs of iron, covered with cloth, or sometimes iron with holes in it. The carcass, being filled with combustible materials, is thrown from a mortar into a besieged place with a view to set the buildings on fire.

CA'RCERES. (Lat. carcer, *a prison.*) In Ancient Architecture, the cells at the end of a circus, in which were stationed the chariots and horses that contended for the prizes, so that they might be able to start simultaneously at the given signal.

CARCE'RULUS. (Lat. dim. of carcer, *a little prison.*) A name given by botanists to such fruits as those of the lime tree, the *Tropæolum*, &c.; which consist of a small number of dry indehiscent few-seeded cells cohering round a central axis.

CARCINO'MA. (Gr. καρκινος, *a cancer.*) A cancerous tumour.

CA'RDAMOMS. Seeds of the *Alpinia cardamomum*. These seeds are imported from Bengal: there are several varieties; but those pods which are small, short and thick, and heavy, are preferred. The seeds themselves are very pungent and aromatic; the containing capsule is quite insipid. Their chief use is in medicine, especially in combination with cathartics and bitters. They yield an essential oil by distillation, to which their virtues are to be ascribed.

CA'RDIAC. (Gr. καρδια, *the heart.*) Belonging to or connected with the heart. The superior opening of the stomach is called the *cardia*, or *cardiac end*, from its proximity to the heart.

CA'RDIA'CEANS, or CARDIACEA. (Lat. cardium, *a cockle.*) A numerous and beautiful family of Lamellibranchiate Dimiary Bivalve Mollusks, including those species in which the mantle is open anteriorly for the foot; and also has two distinct orifices, one for respiration, the other for excretion, as in the cockle (*Cardium edule*). The shell is characterized by having at the hinge irregular primary teeth, both in form and situation, and generally accompanied by one or two lateral teeth. The genera composing this family are *Isocardia*, *Hiatella*, *Cypricardia*, *Cardita*, *Cardium*.

CARDIA'LGIA. (Gr. καρδια, and αλγος, *pain.*) Anxiety and pain about the region of the stomach, frequently attended by a sense of gnawing and heat, and hence called *heartburn*. It is a common symptom of indigestion, and accompanied by salt and acid eructations. After excess in eating and drinking, a fit of heartburn may often be prevented by a teaspoonful of carbonate of magnesia, taken in cinnamon or in soda water, at bed time; 20 or 30 grains of bicarbonate of soda in cold chamomile tea is also an effective preventive. Where the disease is symptomatic of organic mischief, these antacid remedies must be cautiously administered.

CA'RDINAL. (Lat. cardo, *a hinge.*) An epithet implying importance; in which sense it is applied to the principal virtues, the four points of the compass, &c.; and in theological language originally to parish churches, as distinguished from chapels and oratories; from whence it was transferred to the clergy who ministered in such churches. In later times the epithet was restricted to the seven bishops of Rome, and the sees within its territory, and the clergy of the eight and twenty principal churches of that city: from whence the college of cardinals takes its origin. The number of which this college consisted has varied in the course of time. It has for some centuries been limited to seventy; of whom six are bishops, fifty presbyters, and fourteen deacons; and the election of the pope, which is performed by these personages assembled in conclave, is thus concurred in by the three orders of clergy through their representatives. The period at which this election was confined to the cardinals is variously stated. Some have asserted that such was the case as early as 1058; others not before 1562. It is now understood that the pope must be chosen from among this body. The cardinals are distinguished by a scarlet hat, and a short purple mantle worn over the rochet. Their rank is next to that of the pope, to whom they form a political and ecclesiastical council. For further details on the duties of cardinals, see CONSISTORIUM and CONCLAVE.

CA'RDINAL POINTS. (Lat. cardo, *a hinge.*) In Geography, the east, west, south, and north points of the horizon. In Astrology, the cardinal points are those of the rising and setting of the sun, and the zenith and nadir. (COMPASS.)

CA'RDIOID. (Gr. καρδια, *heart*, and ειδος, *form.*) An algebraic curve, so called from its resemblance to a heart.

CARDI'TIS. Inflammation of the heart.

CARDOO'N. A kind of artichoke. The *Cynara cardunculus*.

CARDUE'LIS. (Lat. carduus, *a thistle.*) A genus of Conirostral Perchers (*Insessores*) or Passerine birds, of the finch tribe (*Fringillidæ*), including the goldfinch (*Carduelis elegans*), aberdevine (*Carduelis spinus*), and other British siskins, the habits of which are less arboreal than in the true finches, and which feed principally on the seeds of the thistle and other composite plants.

CAREE'NING. The laying of a ship over to get at leaks or injuries in the bottom. This is commonly called heaving down. To careen implies also to *heel* or lie over generally. Heaving down is never practised with a large ship, except where there are no docks, as the great forces which must be applied to the mast heads to get her over are liable to strain the hull.

CA'RET. (Lat. careo, *I am wanting.*) In Grammar, a character in this form ʌ, denoting that something has been omitted, and is interlined.

CARIA'MA. *See* DICHOLOPHUS.

CA'RICATU'RE. (It. caricare, *to load* or *charge.*) In Painting, an exaggerated representation of any object, in which any natural defects are overcharged, so as to make it appear ridiculous.

CARI'CHIUM. (Lat. carex, *sedge.*) A genus of land-snails, so called from their habitat among sedge, wet leaves, grass, &c. Of these sedge-shells, *Carichium minimum* is British, and may be found about Acton.

CA'RIES. A decayed bone or tooth.

CARI'LLON. A tune performed upon bells.

CARI'NA. (Lat. carina, *the keel of a boat.*) In Botanical language, is the sharp thin back of any organ; the back of a leaf folded up if thin and sharp, the winged rim that occupies the back of certain fruits, the sharp-backed part of a glume or bract, all bear this name. It is also applied to the two anterior petals of a Papilionaceous flower, which adhere by their lower edges into a body something like a boat.

CARINA'RIA. (Lat. carina, *a keel.*) A genus of

Heteropodous Mollusks, characterized by having the viscera, as the heart, liver, branchiæ, generative organs, &c., protruded from the body, and encased in an extremely fragile, beautiful, sub-transparent, symmetrical, compressed shell. The summit of the shell is slightly involuted, but never enters the aperture; the convexity of the shell is terminated by a single keel.

CA'RINATE. (Lat. carina, *a keel.*) In Zoology, when a surface has a longitudinal elevated line, like the keel of a vessel.

CA'RMELITE. *See* ORDERS, MENDICANT.

CA'RMINE. A brilliant lake, made of the colouring matter of the cochineal insect combined with alumina and a little oxide of tin.

CA'RMINATIVE. (Lat. carmen, *a verse or charm.*) Medicines which allay flatulency, and pain of the stomach and bowels arising from it.

CARNA'TION. (Lat. carneus, *flesh-coloured.*) A favourite florist's plant, obtained by art from the wild *Dianthus caryophyllus*. Its flowers are deliciously fragrant; and although in the unimproved state they are a uniform deep red, they have been rendered beautifully striped and variegated by successive changes in the hands of the gardener. The most succesful cultivators of carnations are the Germans, who possess some hundred varieties, and supply the principal part of the seed used in other parts of Europe. These varieties are arranged in three classes, *flakes*, *bizarres*, and *piccotees:* the first have ten colours in their flowers, and broad stripes; the second have irregular spots and stripes, and not fewer than three colours; the last are spotted or dotted with scarlet, red, purple, &c., upon a white or yellow ground.

CARNA'TION-GRASS. (Lat. caro, *flesh.*) Any coarse species of carex is so named in the north of England and Scotland.

CARNA'TIONS. (Lat. caro, *flesh.*) In Painting, the parts of a picture which represent the naked limbs, &c.

CARNE'IA. (Gr. καρνεια.) A festival observed in most of the cities of Greece, and especially at Sparta, in honour of Apollo, surnamed Carneius. The festival lasted nine days, and was conducted in imitation of the method of living in camps; for nine tents were erected, in each of which nine men of three different tribes lived nine days.

CARNE'LIAN. A red or flesh-coloured calcedony. The finest specimens come from India, and are in great request for seal-stones, beads, &c.

CAR'NEONS. (Lat. caro, *flesh.*) A soft fleshy substance.

CA'RNIVAL. (Lat. carni vale, *farewell to meat.*) A festival celebrated with much merriment and revelry in Catholic countries, and especially at Rome and Venice, during the week before the commencement of Lent; deriving its Italian name from the farewell to flesh or meat which introduces the great fast of the church.

CARNI'VORA. (Lat. caro, *flesh*, and voro, *I devour.*) The second tribe of Cuvier's order *Feræ* (*Carnassiers*), including those species of which the teeth are peculiarly adapted for destroying living prey, and for tearing, dividing, or bruising flesh. They have incisors in each jaw, two long and pointed canines; and the molars are never beset with small conical points or tubercles, as in the insectivorous tribe of the same order. The carnivorous tribe is divided into those which tread on the sole of the foot (*Plantigrades*), and those which run on the last joints of the toes (*Digitigrades*).

CAROCO'LLA. (Lat. caro, *flesh;* and Gr. κολλη, *glue.*) A genus of land-snails, so named from the tenacity with which their fleshy foot adheres to limestone rocks. The variegated carocolla (*Car. lapicida*, Lam.) is a native species, and has been found on Juniper Hill, Box Hill, Surrey.

CA'ROMEL. Sugar melted till it acquires a brown colour and exhales a peculiar odour.

CARO'TID. An artery of the neck. There is one on each side of the cervical vertebræ which supply the head with blood. If these vessels are tied, the animal becomes insensible; hence the term, from καροω, *I put to sleep.*

CARP. *See* CYPRINUS.

CA'RPADE'LIUM. (Gr. καρπος, *fruit*, and δηλος, *plain.*) A little-used name, applied in botany to all indehiscent, many-celled, inferior fruits, with a single seed in each cell; as in Umbelliferous or Apiaceous plants.

CA'RPEL. (Gr. καρπος, *fruit.*) A name contrived by modern botanists to denote the separate pistils out of which a fruit, consisting of more pistils than one, is composed. In its most simple state a fruit consists of a one-celled ovary, and a style and stigma, united into a pistil, as in the plum; but in most cases several such pistils are formed within the same flower, and are united in various ways into one compound body, to which the name of pistil is also applied. In the latter case the single pistils are called carpels. The pistil may nevertheless consist of one carpel only. The theory of the structure of the fruit of plants turns upon the relative position which carpels bear to each other in their united state; and upon their correspondence in this respect with leaves, of which they are undoubtedly modifications.

CA'RPENTER. The third warrant officer on board a man of war. He has the charge of the boats. It is his duty, with his mates, to attend constantly to the state of the well, in order that a leak may be immediately reported.

CA'RPENTRY. (Lat. carpentum, *carved wood:*) In Building and Architecture, an assemblage of pieces of timber connected by framing or letting them into each other, as are the pieces of a roof, floor, centre, &c. It is distinguished from *joinery* by being put together without the use of other edge tools than the axe, adze, saw, and chisel; whereas joinery requires the use of the plane. The leading points to be attended to in sound carpentry are, 1st, The quality of the timber used; 2nd, The disposition of the pieces of timber, so that each may be in such direction, considered with reference to the fibres of the wood, as to be most capable of performing its office properly; 3rd, The forms and dimensions of the pieces; 4th, The manner of framing the pieces into each other, or otherwise uniting them by means of iron or other metal.

CA'RPET. An ornamental covering for the floor. The manufacture of carpets is carried on in great perfection in this country. The principal varieties are the Brussels, Axminster, Wilton, Kidderminster, and Venetian. They are generally composed of linen and worsted. In some the pile is cut so as to give the carpet the character of velvet; as in the Wilton carpets. Kidderminster or Scotch carpets are entirely fabricated of wool.

CA'RPET WAY. Any strip or border of green sward left round the margin of a ploughed field.

CA'RPOBA'LSAMUM. (Gr. καρπος, *fruit*, and βαλσαμον, *balsam.*) The exudation of the fruit of the *Amysis Gileadensis;* a variety of *balm of Gilead.*

CA'RPOLITES. (Gr. καρπος, *fruit*, and λιθος, *a stone.*) Fossil fruits and seeds.

CARPO'PHORUM. (Gr. καρπος, *fruit*, and φερω, *I bear.*) The name of the central column, which, in the fruit of the Geranium, the Euphorbia, or Apiaceous plants, bears the ripe carpels, and holds them together when they attempt to separate at maturity.

CA'RREL, or QUARREL. The arrow used in cross-bows, the head of which was four-sided; a cross-bow bolt.

CA'RRONADE. A kind of short iron gun, which is attached to its carriage by a joint and bolt underneath the piece, instead of trunnions. It is only in this respect and in its dimensions that it differs from other guns or howitzers. The name is derived from Carron, a village in Stirlingshire, where this gun was first made.

CARSE LAND. Alluvial soil in a state of aration.

CART. An open box, placed upon two or more wheels, and constructed with shafts, so as to admit of being drawn by one or more horses. In agriculture, carts are used for carting or carrying from one point to another soils, manures, and produce. For this purpose there are the close cart, single or double, that is, for one or for two horses; the corn cart, single or double, constructed of open work, and used for carrying hay, and for conveying corn in the sheaf from the field to the rickyard, &c.; and the stone or quarry cart, consisting of a strong bottom and low wheels, for conveying large stones. Besides these, there are the three-wheeled cart, with low wheels, for carting soil, stones, &c., to a short distance; the timber cart, which is nothing more than two pairs of wheels and axles joined by a pole, and used for conveying large trunks of trees from the place where they have been felled to the place where they are to be manufactured; and the box cart, or cart with close bottom and sides, which is used for conveying soils, manure, and small articles, commonly constructed so as to admit of discharging the load by elevating one end of the box and lowering the other; and to carts having this contrivance the term coup cart is applied in Scotland, and till cart in England.

CARTE BLANCHE. (Fr.) A paper containing nothing but the signature of the party who grants it, in order that the party to whom it has been delivered may insert such conditions as he chooses to prescribe. This term is used in a general sense to express an unlimited authority delegated by one individual to another: thus a general is said to have carte blanche, when his sovereign has granted him permission to use his own discretion in conducting the operations of war.

CA'RTEL. In Military language, an agreement for the exchange of prisoners. Also, a challenge to fight a duel. A cartel ship is one commissioned, in time of war, to carry proposals of any kind between belligerent powers.

CARTE'SIAN PHILOSOPHY. The philosophical system of René des Cartes (born 1596), a native of France, perhaps the most original thinker that country has produced. Des Cartes was the contemporary of Bacon, and exercised an equally powerful influence, though in a manner widely different, on the progress of philosophy in Europe. Both equally undertook the task of demolishing the old scholastic system, and of substituting in its place a more comprehensive method and a more living

spirit of philosophising. But what Bacon strove to accomplish by calling men's attention to experiment and observation of nature, Des Cartes proposed to attain by the search for a first and self-evident ground of all knowledge. This he finds in the art of consciousness, involving necessarily the idea of self or mind. (*Cogito ergo sum.*) Consciousness is the act of thought, constitutes the essence of the soul, and is that which distinguishes it from matter. The ideas or objects of consciousness are of three kinds,—acquired, compounded, and innate. Of the last sort is the idea of God, or the Absolute Being, which, as being the ground of all reality, is itself its own demonstration. God, the Author of the universe, upholds it in its course by his perpetual co-operation, or, in Cartesian language, assistance. All physical phenomena Des Cartes endeavoured to account for by his celebrated *vortices*—motions excited by God, the source of all motion. The singular mixture of philosophical depth and extravagant hypothesis that prevails in the writings of this philosopher obtained for him, as might have been expected, a large number of warm adherents, and of equally violent opponents. Among the former may be enumerated the celebrated Pascal, Malebranche, and Spinoza. The two latter deviated indeed in many important points from the views of Des Cartes; but the main features of his philosophy are preserved alike in the religious mysticism of the one and the systematic pantheism of the other.

CA'RTHAMUS. *See* SAFFLOWER.

CARTHU'SIANS. In Ecclesiastical History, a religious order, instituted by St. Bruno in 1086: so called from their original seat, Chartreuse. They followed the rule of the Benedictines (quod vide), with the addition of various austerities, and employed themselves in the same literary and mechanical pursuits. Soon after their institution the Carthusians were introduced into England, where in the lapse of time they succeeded in establishing nine houses of their order, among which was the Charterhouse in London. (See *Histoire des Ordres Monastiques*, vol. vii.)

CA'RTILAGE, CARTILAGO. (Lat. caro, *flesh*.) A white elastic substance, intermediate between bone and ligament, and having the chemical properties of condensed albumen. It is commonly called *gristle*.

CARTILAGI'NEANS, CARTILAGINEI. A subclass of fishes, in which the endo-skeleton never passes beyond the primitive condition of gristle or cartilage. *See* CHONDROPTERYGII.

CARTOO'N. (It. cartone.) In Painting, a sketch made as a pattern for tapestry. The name is also given to large sketches on coarse or other paper for fresco subjects; in which case, when the stucco is setting the outlines are pricked through on to it so that a correct outline may be expeditiously obtained. We subjoin the following account of the cartoons of Raffaelle at Hampton Court.—These celebrated works, originally thirteen in number, are a magnificent series of coloured designs, representing the origin, sanction, economy, and progress of the Christian religion. They were made originally for the copies in tapestry, still, we believe, annually exhibited in the colonnade of the Vatican, wrought at Arras by command of Leo X. at an expense of 7000 crowns of gold. These were carried off at the plundering of Rome in 1527 by the Spanish army; but Montmorenci, the French general, found and restored them to their former station. In our own days they were again carried off when the French seized the government of Rome, and were afterwards purchased by that excellent pontiff Pius VII.

Seven of the original pictures were purchased by Charles the First, and are now preserved at the royal palace at Hampton Court. Richardson (*Theory of Painting*) gives an historical and critical description of them, and considers them better calculated to convey a true notion of the genius of Raffaelle than even the loggia of the Vatican. The object that Charles had in view when he purchased the seven cartoons above mentioned, was to supply the manufacture then at Mortlake with subjects of a higher character than Francis Cleyre, its superintendant, could himself invent; and there is evidence that some of them were actually copied there, and that they are still preserved, probably at Petworth.

In whatever light, says Fuseli, we consider their invention—as parts of *one whole* relative to each other, or independent *each of the rest* and as single subjects,—there can be scarcely named a beauty or a mystery of which the cartoons furnish not an instance or a clue. They are poised between perspicuity and pregnancy of moment: the Death of Ananias, the Sacrifice at Lystra, Paul on the Areopagus, will furnish us with conclusions for the remainder. In Paul announcing his God from the height of the Areopagus, the same sagacious critic observes that enthusiasm and curiosity make up the subject. Simplicity of attitude invests the speaker with sublimity; the parallelism of his action invigorates his energy; situation gives him command over the whole; the light in which he is placed attracts the first glance; he appears the organ of a superior power. The assembly, though selected with characteristic art for the purpose, are the natural offspring of the place and moment. The involved meditation of the Stoic, the Cynic's ironic sneer, the incredulous smile of the elegant Epicurean, the eager disputants of the academy, the elevated attention of Plato's school, the rankling malice of the Rabbi, the magician's mysterious glance, repeat in louder or in lower tones the novel doctrine; but whilst curiosity and meditation, loud debate and fixed prejudice, tell, ponder on, repeat, reject, discuss it, the animated gesture of Dionysius and Damaris announce the power of its tenets, and—what the artist chiefly aimed at—the established belief of immortality. We have selected the above as a specimen of the critical examination which the reader may apply to the remaining six of this extraordinary series of pictures, in which the power of combining the drama with pure historic fact has never been surpassed.

The cartoons have been several times engraved; first by Gribelin in the reign of Queen Anne; then by Dorigny; and afterwards by inferior artists, most probably from the engravings themselves of those that preceded them. They were likewise engraved on a small scale by Fittler, and more recently in a superior style by Holloway. The late Prince Hoare, Esq., secretary for foreign correspondence to the Royal Academy, was possessed of a very fine cartoon by Raffaelle, the subject of which was the Murder of the Innocents.

CARTOU'CH. (It. cartoccio.) In Architecture, the same as *modillion* (which see), except that this term is used almost exclusively to signify the blocks or modillions applied at the eaves of a house. Some have used the term to denote the ornament of the key-stone of an arch, which seems to represent a scroll of paper partly unrolled.

CARTOU'CHE. A Military term, signifying a strong case or box for holding balls.

CA'RTRIDGE. A case of paper or pasteboard holding the exact charge of a firearm. Those of cannon and mortars are sometimes of tin or wood, but most frequently flannel, bags of this material being found the most convenient.

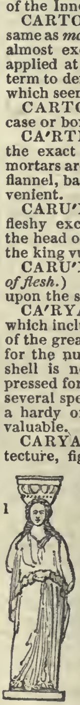
CARU'NCLE. (Dim. of caro, *flesh*.) A naked soft fleshy excrescence, often ornamenting some parts of the head of birds; as, *e.g.* the caruncle on the cere of the king vulture (*Vultur papa*, Lin.).

CARU'NCULA. (Dim. of caro, *flesh; a little piece of flesh*.) A small protuberance found near the hilum upon the seed of *Euphorbia lathyris* and other plants.

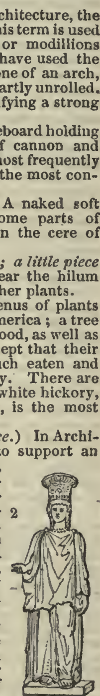
CA'RYA. (Gr. *κάρυον, a nut*.) The genus of plants which includes the hickory nut of North America; a tree of the greatest value, for its tough elastic wood, as well as for the nuts, which resemble walnuts, except that their shell is not furrowed, and which are much eaten and pressed for their oil in their native country. There are several species of Carya; but *C. alba*, the white hickory, a hardy ornamental tree in this country, is the most valuable.

CARYA'TIDES. (Gr. *καρυα, a nut tree*.) In Architecture, figures used instead of columns to support an entablature. The origin of them, according to Vitruvius, is as follows—"Carya, a city of Peloponnesus, took part with the Persians against the Grecian states. When the country was freed from its invaders, the Greeks turned their arms against the Caryans, and upon the capture of the city put the males to the sword, and led the women into captivity. The architects of that time, for the purpose of perpetuating the ignominy of this people, instead of columns in the porticos of their buildings, substituted statues of these women, faithfully copying their ornaments, and the drapery with which they were attired; the mode of which they were not permitted to change."

1



2



The writer of the articles on art in this work was the first author on architecture who endeavoured to show the want of truth in this account, and that on two grounds:—first, because the circumstance is not mentioned by any of the Greek historians; and secondly, because long previous to the time assigned by Vitruvius, figures of men, women, and animals were employed for this purpose. They appear to have acquired their name from their employment in temples to Diana, by whom the Lacedæmonians are supposed to have been made acquainted with the story of Carya, turned into a nut tree by Bacchus, who at the same time transformed her sisters into stones, and thence worshipped under the name of Caryatis. From their employment in temples dedicated to the goddess, they were used in other buildings as representations of the nymphs who assisted at the mysteries of the patron goddess. The figure No. 1. above given is a Caryatid, from the Pandroseum at Athens; No. 2. is a Canephora (see that word). When figures of the male sex are used they are called Persians.

CARYO'CAR. (Gr. *καρυον, a hard-shelled fruit.*) A genus of trees inhabiting the forests of tropical America, especially Guayana; one of them, found in woods near Mariquita, is said to attain the height of 240 feet. The Saouari (vulgarly called Sawarrow) nuts of the shops, a delicious fruit, with a large soft buttery kernel, are the seeds of *Caryocar glabrum* and other species. Properly the name Saouari applies to *Caryocar butryosum.*

CA'RYOPHY'LLIA. *See* MADREPORE.

CA'RYOPHYLLA'CEOUS (Lat. caryophyllus, *the garden pink*), is sometimes said of corollas consisting of petals having long claws dilating into a broad limb; as in the garden pink.

CA'RYO'PSIS. (Gr. *καρυον, a nut*, and *οψις, resemblance.*) The technical name of the grain of corn. It is an indehiscent one-celled fruit, with a membranous pericarp adhering firmly to the seed.

CASCARI'LLA. (Span. dim. of cascara, *bark.*) The bark of the *Croton eleutheria*, imported for medical use from Jamaica and the Bahama Islands. It is bitter and aromatic, and when burned it diffuses an odour much resembling that of musk.

CASE. (Lat. casus; from cado, *I fall.*) In Grammar, that modification of a noun which designates the relation in which a substance is conceived to exist in regard to some other substance. This end is commonly attained in language by changes in the termination of nouns. In English there are but three cases; the nominative, the genitive or possessive, and the accusative or objective case; the last only in pronouns. All other varieties of relation are expressed by prepositions. *See* GRAMMAR.

CASE. (Fr. casse.) Is the receptacle for the types, from which the compositor gathers them separately, and arranges them in lines and pages to print from. They are always in pairs; one of which is styled the upper case, and is divided into ninety-eight boxes or recesses of equal size, in which are deposited the capitals, small capitals, accented letters, figures, &c.; the other is styled the lower case, and is divided into fifty-three boxes or recesses of unequal size, containing the small letters, spaces, &c., the letters most in use having the largest boxes assigned to them. The cases are two feet nine inches long, one foot four inches and a half broad, and a full inch in depth.

CA'SEIC ACID. A peculiar acid extracted from cheese.

CA'SEMATE. In Fortification, a vault or arch of stonework in the flank of a bastion, serving as a battery.

CA'SEMENT. (It. casamento.) In Architecture, a portion of a window sash hung on hinges. It is used also to denote the moulding called a *scotia*, which see.

CASE'RNS, or CAZERNS. Huts erected on the ramparts, or between the ramparts and the houses, of fortified towns, serving as temporary lodgings for the soldiers on duty.

CASE-SHOT, or CANISTER-SHOT, signifies musket balls, stones, pieces of iron, &c. put into cases or tin canisters, and discharged from pieces of ordnance.

CA'SEUM. (Lat.) The basis of cheese. The purified curd of milk.

CASH. In Commerce, the ready money, bills, drafts, bonds, and all immediately negotiable paper in an individual's possession.

CASSAMU'NAR. A root brought from the East Indies, and formerly used in medicine as a warm bitter.

CASSA'TION, COURT OF. The highest judicial institution in France; so termed from possessing the power to quash (casser) the decrees of inferior courts. It is a court of appeal in criminal as well as civil cases. The tribunal of cassation was first introduced, as a court wholly independent of the king and his council, in 1790. This court has a president, and three presidents of sections; but the minister of justice, as keeper of the seals (*garde des sceaux*), has the right of presiding in cases where it sits on appeal from the cours royales. The three sections are,—1. Des requêtes, which decides on the admissibility of petitions of appeal in civil cases; 2. De cassation civile; 3. De cassation criminelle. The decision of the court of cassation has the effect of sending back the case to the inferior courts. If, after a decision has been reversed, a second court decides the same case in the same way, on appeal being entered again the court of cassation must either repeat its reversal by the unanimous consent of all the three sections, or it must request an authentic explanation of the law from the government; and, after a third conflicting decision, such authentic explanation becomes absolutely necessary. The inferior judges of the three sections of the court of cassation are styled counsellors.

CASSA'VA. A species of starch obtained from the roots of the *Jatropha manihot.*

CA'SSIA. (From the Arabic.) The bark of the *Laurus cassia;* its flavour somewhat resembles that of cinnamon, and it yields an essential oil, which is pungent and stimulant.

CASSI'DEOUS. (Lat. cassis, *a helmet.*) When the upper petal of a flower is dilated into a broad helmet-shaped leaf, as in the genus *Aconitum.*

CASSI'DIDÆ. (Lat. cassis, *a helmet.*) A family of Tetramerous Coleopterans, generally known by the name of tortoise-beetles, distinguished by having straight short filiform antennæ, inserted close together in the upper surface of the head; mouth situated on the under surface of the head, with strong and broad mandibles; legs short, with the tarsi flattened, the third joint deeply cleft, receiving between its lobes the terminal joint; margins of the thorax and elytra much dilated, so as to give the insects the appearance of small tortoises The larva of the *Cassididæ* is remarkable for an apparatus, or anal fork, by which it collects and forms of its excrements a kind of parachute, or defensive covering.

The genera of *Cassididæ* are, *Alurnus, Hispa, Chalepus, Imatidium,* and *Cassida;* the latter is the only indigenous genus, and of this the most common example is the *Cassida equestria* of Fabricius.

CA'SSIOPE'IA. One of the constellations of the northern hemisphere.

CA'SSIS. (Lat.) A genus of Gastropodous Mollusks, separated by Lamarck from the Linnæan genus *Buccinum*, and including the species of which the shells are commonly called "helmets." The nacreous or inner layer of these shells are exquisitely sculptured by Italian artists in imitation of antique cameos; the different coloured strata resembling the onyx and other precious stones.

CA'SSIUS, PURPLE OF. So called from its inventor. A beautiful purple used in porcelain painting, and for staining glass. It is formed by immersing tin in a solution of gold. It is probably a mixture of oxide of tin and finely divided gold.

CA'SSOWARY. (Casuarius, from the Malay word cassuwaris.) A genus of Coursers or Struthious birds, inhabiting the island of Java, in which the wings are shorter than in the ostrich, and are armed with strong spines, for the purpose of combat or defence. The head is surmounted by a bony protuberance covered with horn.

CASSYTHA'CEÆ. (Cassytha, the only genus.) A most singular natural order of plants, having the fructification of *Lauraceæ*, and the manner of growth and general appearance of a *Rhipsalis*, or rather a *Cuscuta.* They inhabit the tropical parts of the world.

CAST. In Sculpture. *See* MOULDING.

CASTA'NEA. (Castana, a city of Thessaly.) A genus of trees or shrubs, related to the oak, and producing for fruit the seed-like nuts called chesnuts in this country. The common Spanish chesnuts, of which upwards of 20,000 bushels are annually imported from the south of Europe, are the fruit of *C. vesca;* a much smaller nut is obtained in North America from the *C. pumila*, or the Chinquapin chesnut. The timber of the common Spanish chesnut is good and durable, more so than that of the oak, when the latter is young; but it is a mistake to suppose that the ancient roofs and beams occasionally found in buildings of the Norman era, and which carpenters call chesnut, are the wood of this tree. Such instances all belong to the kind of oak called *Quercus sessiliflora*. The genus *Castanea* differs from *Quercus*, among other things, in having the nuts enclosed in a spiny closed-up cup, instead of a shallow open one; but in the East Indies, where both oaks and chesnuts assume very remarkable forms, the two approach each other sometimes so nearly in this particular, that it is difficult to distinguish them.

CA'STANETS. (Fr. castagnettes.) Small wooden or ivory musical instruments, played by being tied to the fingers, and thus rattled by dancers to the time of the music of the dance. They are chiefly used in Spain.

CASTE. A term borrowed from the Portuguese settlers in India, which is used to denote the hereditary classes into which the population of Hindoostan is divided, according to the religious law of Brama. The origin of these classes is detailed in the sacred book which contains the ordinances of Menu. According to this authority, the Brahmin, the Cshatriya, the Vaisya, and the Sudra sprang respectively from the mouth, the arm, the thigh, and the foot of Brahma. 1. The class of Brahmins, or priests, whose name signifies *scripture*, are far exalted above the rest in honour and privilege, and should be devoted entirely to prayer and meditation, or at least to the most exalted concerns of life. Many Brahmins, however, do in fact engage in secular pursuits, not only as ministers of sovereign princes (an office for which, according to the ordinances above cited, they are indeed peculiarly fitted), but also, in Guzerat and other parts of Western India, as merchants, or in the lower employment of messengers and porters; while many enter the Company's service as private soldiers. These, however, are Brahmins of the first and second classes (Brachmachari and Grihast'ha), youths or married men who as yet live in the world; from which the two higher classes, Vanaprastha and Sunnyassi, are wholly divorced: from these spring the various orders of fanatics with which India swarms. 2. The Kshatriya, or soldier caste, whose name indicates *protection*. To this belong not only the high military classes, but in some parts of India whole tribes, as the Seikhs, &c. 3. The Vaisya, or commercial class (*wealth*). 4. The Sudra, or caste of tillers of the soil
